He confessed to considerable surprise and disappointment that there was no report from one of these committees especially, and that is the one on Cement Specification. He asked the pleasure of the meeting in regard to the committees which had not reported.

A MEMBER moved that the Council be empowered to reappoint them, or appoint other committees in their place.

Seconded and carried.

NEW BUSINESS

THE PRESIDENT here said in connection with new business he would like to get the proposals of British Columbia before the meeting. It was getting late, but the matter was important. He would be glad to hear from the representatives of the Vancouver Branch.

MR. ROBINSON said there were very many matters which frequently came up before the engineers of British Columbia that could best be taken care of if the large number of engineers residing in British Columbia and members of this Society could in some manner co-operate, to the end that their interests will be taken care of. It had frequently happened that the Society, as a Society, had had to appeal to the Provincial Government on matters which should properly come from the Canadian Society of Civil Engineers at the Montreal headquarters. But, unfortunately, matters moved so quickly in the West that they had not time to institute the proper proceedings and appeal to headquarters here and get action from the Council and return answers to the British Columbia engineers until matters have gone so far as to make it impossible to apply any remedy.

They would like to have this Society give the engineers of British Columbia authority to assemble and transact such business as requires immediate action; but let them have a set of by-laws framed up and thoroughly approved by the Council. Make those by-laws uniform if they wished. They did not desire to separate from the Society of Canadian Engineers, nothing of the kind, and they did not wish even to take any powers of government from the main Society, but they would like to have the main Society make it possible for them to be a unit recognizable by the Provincial Government. Let them realize that this Society is established in British Colnmbia. That was the point.

He had not framed the exact wording of a resolution to carry this into effect, but he thought he could safely leave it in their hands for some impartial person to frame a resolution which will permit the British Columbia engineers to get together in a unit for the protection and the advancement of the profession which they represented.

After a long discussion on the question, the meeting was adjourned, the matter to be further discussed the following day.

(To be continued next week.)

ONTARIO LAND SURVEYORS.

The Ontario Land Surveyors held their twenty-first annual meeting on the 25th, 26th and 27th of February, at the Engineers' Club, King Street West, Toronto. Their banquet, Wednesday evening, was a great success and most enjoyable. Several friends and representatives of sister societies of the association were present to enjoy their hospitality and programme. Among these was the Honorable Mr. Hearst, Minister of Lands, who attended and gave a very fine speech. The programme was as follows, and some of the papers presented will be published in The Canadian Engineer shortly.

TUESDAY, 25th FEBRUARY.

Morning, 10 O'clock.—Meeting of Council of Management; meeting of standing and special committees.

Afternoon, 2 O'clock.—Reading of minutes of previous meeting; correspondence; president's address, T. B. Speight; report of council of management; report of the secretary-treasurer; report of the board of examiners; report of committee on legislation, G. B. Kirkpatrick, chairman; report of committee on publication, A. J. VanNostrand, chairman; report of committee on topographical survey, Thos. Fawcett, chairman; report of committee on exploration, J. F. Whitson, chairman; paper, "Colonization in Northern Ontario," H. M. Anderson; paper, "Aliquot Parts of Township Lots," J. S. Dobie; paper, "Gold Mining in Yukon," E. D. Bolton; paper, "International Boundary Survey East of the St. Lawrence River," Thos. Fawcett.

Evening, 8 O'clock.—Lecture on Panama Canal, A. J. Grant, superintending engineer, Trent Valley Canal, Peterborough; paper, "Modern Engineering Improvements," J. G. Sing, district engineer, Ontario Division Dominion Public Works.

WEDNESDAY, 26th FEBRUARY.

Morning, 10 O'clock.—Report of committee on land surveying, C. J. Murphy, chairman; report of committee on polar research, Willis Chipman, chairman; paper, "Methods of Subdivision of Nine Mile Townships in Ontario," H. J. Beatty; paper, "Subdivision Surveys in Alberta," C. E. Bush; paper, "Boundary Line Between Augusta and Edwardsburg Townships," Willis Chipman; paper, "Notes on Survey Act," C. H. Fullerton; paper, "Diagonal Street Surveys in Great Britain and Canada," T. D. LeMay.

Afternoon, 2 O'clock.—Report of committee on engineering, Owen McKay, chairman; report of committee on Drainage, George Ross, chairman; paper, "Forestry in Ontario," E. J. Zavitz, superintendent of Forestry in Ontario; paper, "Concrete Roads," W. A. McLean, chief engineer, Good Roads Department; paper, "Notes on Wawaitan Power Plant," Robert Laird; report of auditors, J. W. Fitzgerald and R. R. Grant.

Evening, 7.30 O'clock.—Dinner at McConkey's restaurant.

THURSDAY, 27th FEBRUARY.

Morning, 10 O'clock.—Report of committee on repository and biography, L. V. Rorke, chairman; report of committee on entertainment, A. T. Ward, chairman.

W. F. STANLEY & COMPANY, LIMITED.

Owing to the continued expansion of business, the W. F. Stanley & Company, Limited, 4 and 5 Great Turnstile, London, W.C., have been compelled to provide for larger office accommodation and will henceforth occupy the premises at 286 High Holborn, retaining their old quarters for export only. All communications to this firm in future should be sent to their new address.

GOOD ROADS EXHIBIT.

The First Good Roads and Construction Exhibition in Canada proved to be more successful than was generally expected. Held in the Dairy Building, Toronto Exhibition Grounds, on Wednesday, Thursday and Friday, 26th, 27th and 28th of February, the Ontario Good Roads Association Exhibit was advantageous to both members in attendance and to exhibitors. The registered attendance at the convention was over three hundred and represented the different cities, towns and counties of Ontario. Some of the papers presented will be published shortly. The following is a list of the exhibitors with names of some of the representatives who were present:

Abram Cement Tool Co., of Windsor, Ont., was represented by Mr. J. D. Abram, who is the inventor of the Abram automatic cement sidewalk tools. The claim made in connection with these tools (finishing trowel, jointer and edger), is that every 20 hours steady use of a full set will save in labor the cost of the tools. The use of these tools was well demonstrated, and they certainly have enough good points to warrant their trial by every contractor who lays cement sidewalks.

Buffalo Pitts Co., of Buffalo, N.Y. This company imported for the occasion a double-cylinder, steel-geared contractor's road locomotive, with several reversible stone spreading cars, which were demonstrated on the roads outside of the building. Also occupied space in the building. This organization presented a good exhibit. The representatives present were Messrs. F. T. Batchellor, B. F. Hoffman and Jas. T. Mack.

Hugh Cameron & Co.—They represented the Waterous Engine Works Co., of Brantford, and exhibited on the road outside the building a Waterous double-cylinder road roller. The exhibit was in charge of Mr. Hugh Cameron. A Buffalo Pitts scarifier was exhibited in their booth.

Canada Cement Co. was well represented by members of the Ontario and Quebec staffs. They exhibited several models of concrete roads. By means, also, of a small lantern, excellent views of roads, bridges, etc., made of concrete were shown. The representatives present were Messrs. Lapierre, Twoey, Dunlop, Cole, Robertson and Wright.

The Canadian Engineer.—This journal had a booth and was ably represented by Mr. P. G. Cherry, circulation manager. Modesty forbids us to mention all our good points. The great thing was, we were there, ready to help, if possible, and still more ready to dispense information of general interest through the columns of our journal for others. Always we are ready to do this, and we trust our readers will bear it in mind.

Corrugated Pipe Co., of Stratford, Ont., represented by Mr. S. R. McConkey, showed samples of their corrugated iron culverts.

Ontario Bridge Co., of Toronto, erectors of bridges, concrete and steel; also showed some photographs of some of the construction work they have undertaken, and exhibited a special type of road dray. Mr. Edgar Price was in charge.

Ontario Government exhibited six models showing the development of the modern type of road construction. The Roman, French, waterbound, macadam and other types were instructively portrayed. Mr. Gray, assistant to the Chief Engineer of Highways of Ontario, had charge of the exhibit.

Ontario Rock Co., of Toronto, exhibited samples of trap rock. The company was represented by the general sales agent, Mr. W. A. Stewart.

Paterson Manufacturing Co., manufacturers of Tarvia Pavements, was represented by Messrs. Smith and Barnett. The claims for "Tarvia" are that it will, in one of its forms or another, solve every Macadam road problem, provide a dustless, cheaply maintained surface, and reduce general road costs. The booth was in a prominent corner and had many visitors.

Rocmac (Ontario) Limited, exhibit was in charge of Messrs. Allen and Seers. Photographs of roads constructed of Rocmac were shown. Many enquiries were received from interested members attending the convention.

Sawyer-Massey Co., of Hamilton, Ont., exhibited their machinery both inside and outside of the building. At the inside exhibit there was shown a stone crusher; outside was demonstrated a Sawyer-Massey steam road roller. This company also manufactures gas tractors, as well as a full line of road-building machinery. Mr. E. Crawford, manager of the good roads machine department, was the representative in charge.

United States Steel Products Co. showed samples of Triangle Mesh concrete reinforcement. The exhibit was in general charge of Messrs. Fred and C. H. Brurcke, the Toronto managers.

Wettlaufer Bros., of Toronto, showed a Wettlaufer traction mixer, with heart-shaped drum, a Mitchell stone crusher and other machinery such as concrete brick-making machinery, etc. This interesting exhibit was in charge of the Wettlaufer brothers and attracted a great deal of attention.

Other companies than those exhibiting were represented at the show. Among them were:

The Barber Asphalt Paving Co., of Philadelphia, represented by Mr. Gordon Smith, of Montreal, and Mr. P. S. Coyne, of Buffalo.

Lecky and Collis, of Napanee, Ont., manufacturers of Napanee rock drills and hoisting engines, and sales agents for Austin cube mixers and trench excavators, Priestman buckets, etc. Mr. Collis represented the company at the show.

The Thew Automatic Shovel Co., of Lorain, Ohio, represented by Mr. H. A. McLaughlin.

The Asphalt and Supply Co., of Montreal, represented by Mr. O. G. Carscallen, the Toronto manager.

The Hagersville Crushed Stone Co., represented by Mr. Robert Hambleton, of Hagersville, the president of the company.

The M. Rumely Co. Inc. of La Porte, Ind., manufacturers of steam and oil tractors and grader attachments.

COAST TO COAST.

Ottawa, Ont.—The revenue of customs receipts for the eleven months ending February 28 was $103,485,000, compared with $17,716,000 for the corresponding eleven months of the last fiscal year. This shows an increase of $25,-769,000 or, in other words, the increase for the eleven months of this fiscal year is greater than the entire customs revenue for the fiscal year 1898-99, which was $25,734,000. The revenue for the month of February was $9,155,000, and for the corresponding month last year $7,447,000, being an increase of $1,707,000.

Port Nelson, B.C.—The cost of surveys of the 420 miles of new road from Le Pas to Port Nelson, which have been made, amounts to $156,430. The construction up to date on McArthur Bros.' contarct has cost $354,830. Supplies, including rails, etc., have cost $105,343, while the bridge over the Saskatchewan at Le Pas was erected at a cost of $108,000.

Ottawa, Ont.—At a recent session of the Senate Senator Chaquette asked for papers relating to the proposed Quebec drydock, which has been under consideration for the past fifteen years without anything definite being done. Senator Power said as there was a great dock in Montreal there did not seem to be justification for the expenditure of a large amount of government money to build another dock so near as the city of Quebec. There would not be enough work for the two docks, and the expense of maintenance would be thrown on the government.

Ottawa, Ont.—The board of control of this city are applying to the Federal Government and also to the governments of Ontario and Quebec to secure the necessary legislation to permit the city to get a supply of water from the lakes of the Gateneau hills. This is the recommendation of the British experts, who estimated the cost to be $7,000,000.

Montreal, P.Q.—The firm of B. J. Coghlin Company, Limited, advise that they are leaving their present offices on St. Paul Street, corner of St. Francois Xavier, on or about the 1st of March, to occupy the new buildings erected next to their factory on Ontario Street East, Montreal. For almost fifty years their name has been associated with St. Paul Street, and while loath to leave a locality where they are well known, increase of business necessitates it.

PERSONAL.

WILLIAM N. ASHPLANT has been appointed city engineer of London, Ont.

MR. W. H. BEMAN, of Montreal, has been appointed commissioner in charge of the street paving for the city of Sherbrooke, Que.

JAMES IRVINE, resident engineer of the Canadian Pacific Railway at Kingston, has been moved to Toronto. L. S. Rudder, of Toronto, will take his place.

MR. PERCIVAL LANCASTER has been appointed city engineer of Belleville, Ont., in succession to James G. Lindsay. Mr. Lancaster commences his duties at once.

JAMES HUTCHEON, ex-city engineer of Guelph, Ont., has accepted a position in the Department of Lands, Forests and Mines at Toronto. He will remain a resident of Guelph for the present year at least.

M. H. BAKER, city engineer of St. Thomas, Ont., has been appointed city engineer of Prince Albert, Sask. It is understood that Mr. Baker will commence his duties in Prince Albert almost immediately.

ALAN FRASER, B.A.Sc., has beeu appointed engineer to the Toronto Iron Works, Toronto. He leaves the office of the district engineer of the Canadian Northern Railway this week to enter into his new duties.

MR. C. H. CUNNINGHAM has just entered into his new position with the Thor Iron Works of Toronto, of which company he is a director. Mr. Cunningham has been associated with Frank Barber, civil engineer, of Toronto, for the past two years.

HUGH GALL, B.A.Sc., has been appointed assistant engineer to Frank Barber, consulting engineer and engineer to the county of York. Mr. Gall will be remembered as having led the Rugby team of the University of Toronto in several of its inter-collegiate and national victories of the last few years.

FRANCIS H. PARR, of the Institution of Municipal and County Engineers, and the Royal Sanitary Institute, has been appointed as permanent engineer for the municipality of Kildonan. He has had ten years engineering experience

in different public works carried on during that time in the suburbs of London. There were about forty applications for the position.

THOS. C. KEEFER, C.M.G., LL.D., of Ottawa, past president of the Canadian Society of Civil Engineers, and also the American Society of Civil Engineers, has been elected honorary member of the Institution of Civil Engineers. Some idea of the extent of the honor conferred may be gained by the fact that there were only twenty honorary members in in 1912, including H.I.M. the Emperor of Germany, H.R.H. the Duke of Connaught, Prince Auguste D'Arenberg, Lord Alverstone, Earl Brassey, Rt. Hon. Joseph Chamberlain, Earl of Cromar, Earl Curzon, Viscount Kitchener, Duke of Northumberland and Lord Strathcona.

COMING MEETINGS.

THE CLAY PRODUCTS EXPOSITION.—To be held in the Coliseum, Chicago, Feb. 26th to Mar. 8th.

AMERICAN INSTITUTE OF CONSULTING ENGINEERS.—A meeting for the purpose of further discussing "Professional Relations," will be held at the Engineers' Club, 32 West 40th St., New York City, Tuesday evening, 8 p.m., March 11, 1913. Secretary, Eugene W. Stern, 103 Park Ave., New York City.

THE CLEVELAND ENGINEERING SOCIETY.—Regular meeting, Chamber of Commerce Bldg., March 11th, 1913. Illustrated Paper on "Storage Batteries," by H. H. Smith, Chief of Research Dept., Edison Storage Battery Co., Orange, N. J. Secretary, David Gaehr.

ILLINOIS WATER SUPPLY ASSOCIATION.—The Fifth Annual Meeting of the Association will be held at the University of Illinois, Campaign-Urbana, Ill., March 11th and 12th, 1913. Secretary, Edward Bartow.

CANADIAN MINING INSTITUTE.—Annual Meeting will be held at Chateau Laurier, Ottawa, March 5th, 6th and 7th. H. Mortimer Lamb, Windsor Hotel, Montreal, Secretary.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, T. S. Young, 220 King Street W., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memorial Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, P. Pardo Wilson, Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

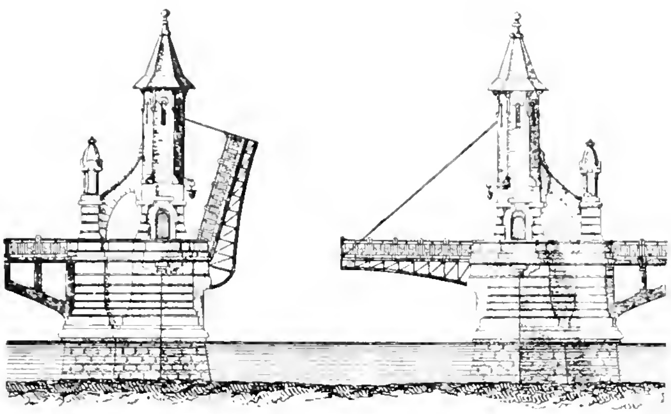
An Engineering Weekly

BASCULE BRIDGES

By H. G. TYRRELL.*

Early French Bascules.—The Belidor system of drawbridges, invented by M. Belidor in 1810, consists of a leaf or platform hinged at one side of the waterway and supported at the outer end by chains or cables passing up over elevated sheaves on the shore structure, either castle wall or tower, and fastened to two separate rolling counterweights, one at each side of the roadway, moving on curved tracks of special form, the outline being called a "sinusoid." The essential idea of the invention is that the centre of gravity of all moving parts, including both leaf and counterweight, travel on a horizontal line. Instead of one large rolling weight at each side, two or more smaller ones connected together may be used.

A modification of the Belidor system was invented prior to 1820 by Captain Délille, who proposed joining the rollers with the outer end of the platform by a bar or stiff member instead of a flexible cable, and working them by an endless chain. When the drawbridge adjoined a building or walled enclosure, vertical grooves for the bars were left in the masonry at each side of the roadway, but, as in the Belidor design, the centre of gravity of all moving parts still travelled horizontally. Equipped in this way, the bridge was very easily worked by hand, and because of its simplicity came rapidly into favor. Exact methods for determining the outline of the "sinusoid" were evolved and the construction henceforth presented no difficulty. The two rolling counterweights were sometimes connected by a shaft or stiff member across the roadway, and in open situations apart from buildings the curved tracks were supported by timber framing.



Bascule in Spain.

A further modification of the methods of Belidor and Délille appeared prior to 1840, the invention of Colonel Bergére. The counterweight in this case described precisely the same curve as in the former methods, but the weight of leaf and balance is supported by a connecting bar or lever mounted at its centre on wheels which roll back and forth on a horizontal track, the principle being similar in this respect to a recent American patent. Another of Colonel Bergére's designs shows the connecting lever mounted on large wheels with their treads at the roadway level instead of smaller wheels on an elevated track.

Mr. J. C. Ardagh, of the Royal Engineers, devised a system somewhat similar to Belidor's, with the platform supported by chains passing over sheaves and connecting at the rear to counterweights which, instead of travelling on a rigid curved track of special form, were guided in their course by other cables, the ends of which were fastened in the proper positions, that the rolling sheaves would describe exactly the same curve as that followed in the Belidor and Délille systems. The bridge was balanced in all positions. Dobenheim's draw was counterweighted with blocks or bars on the chains, the weight being great enough to balance the platform when horizontal, but it was in complete equilibrium in only 3 positions. The Noggerath system was somewhat similar.

An opening span of the Belidor type was incorporated in a design proposed in 1885 by Ordish and Matheson for crossing the Thames at London, and since then several have appeared in America, one of the first being a railroad bridge over the Morris Canal, between Jersey City and Lafayette, completed in 1890. It was all framed in timber and was worked by hand power. The leaf was 25 feet long and the whole draw weighed only 3 tons. Counterweights were 3 feet in diameter.

Another bridge, completed in 1896, to carry four tracks of the Erie Railroad over Berry's Creek, on the Hackensack meadow near Rutherford, N.J., had a span of 32 feet and a clear opening of 24 feet, and at the time was the largest of its kind. It was 44 feet wide between outside girders, and had a total weight of 70 tons. Beside the moving span, it had two fixed plate girders 50 feet long. The counterweights were 6½ feet in diameter, each one weighing 51,000 pounds. They consisted of several circular parts fastened together with bolts, the heads of which at each side were countersunk into the casting. The four railroad tracks were 13 feet apart on centres and were each supported on a pair of deck plate girders. The bridge was operated by hand power by means of 9/16-inch wire ropes passing over 23-inch sheaves.

The longest bridge of the kind and the first important bascule in America was completed in 1897 over the river at Michigan Avenue, Buffalo, N.Y., the span being 153 feet between trunnions and 150 feet between piers. It has two

---

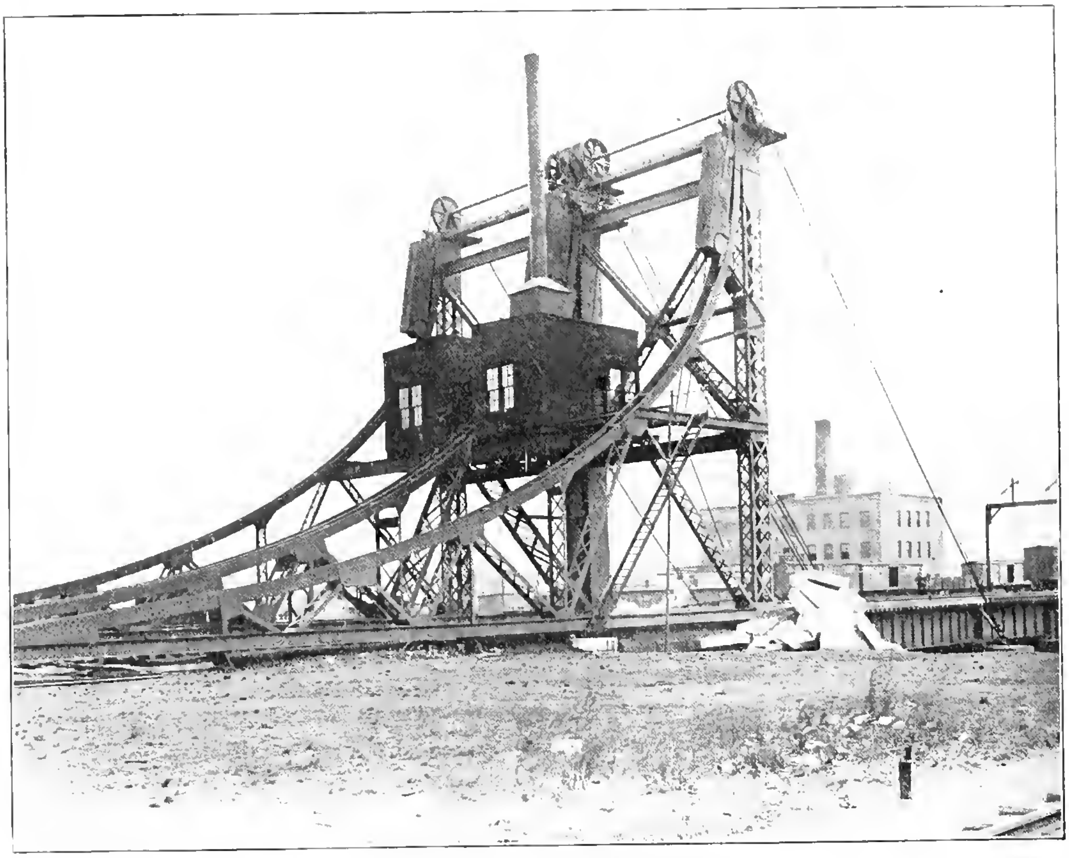
* Consulting Engineer, Evanston, Illinois.

leaves with trusses 77 feet long and 9 feet deep, drawn up by ropes attached to shore towers 77 feet high. Each counterweight consists of ten castings 6½ feet diameter and six others 5½ feet diameter, mounted on a 6-inch shaft 8 feet long. The weights running on double rails are attached to the leaves by four 1½-inch crucible steel cables worked by steam power. At each side of the centre opening is an approach span. The dead weight of each leaf is 60 tons, and the total counterweight at each side is 70 tons. It has a central road 22 feet wide and a 6-foot walk outside each of the trusses. The superstructure cost $38,700, on which there was probably a considerable contractor's loss. It is opened forty to fifty times per day and can be operated by steam power in one minute by means of 6-inch screws 18 feet long, lying horizontally, and attached at one end to the trusses at the upper shore panel point. The screws have three threads ¾ inch square and 4½-inch pitch.

The bridge over the west fork of the south branch of the Chicago River for the Chicago Terminal Transfer Railroad has a clear span of 61 feet, with girders 70 feet long, and was completed in 1899 from plans by George S. Morison. Two ropes and one chain are attached to each of the counterweights, the chains having a rigid hold on the sheaves, while the ropes carry all or most of the load. Provision was made at first for two spans meeting on a centre pier, but the towers and lifting machinery were put in for one span only. The light centre pier gives rigid bearing to the girders and offers less obstruction in the channel than would the centre pier of a swing bridge. Since it was first built the bridge has been raised 4 to 5 feet with new masonry. It has four tracks with sixteen girders 70 feet long and eight girders 27 feet long. The part that is moved is underbalanced in its lower position and overbalanced in its upper position, thus requiring power to start it from either extremity. After its completion, the designer stated that if building another one he would have it underbalanced throughout, and would raise and lower it with a winding engine. The bridge is in two parts, each of which can be operated separately. The sheaves at the tower are six feet in diameter and each counterweight weighs 27 tons.

The Harway Avenue lift over Coney Island Creek, at Brooklyn, was completed in 1898 at a cost of $25,000. The clear span is 50 feet and it is worked by a five-horse-power electric motor, but has also hand power gearings. It is 31 feet wide between railings, and has three main girders 10 feet apart on centres. Each counterweight weighs 45,000 pounds and is supported by 1¾-inch ropes passing over sheaves at the top of towers which are 35 feet high.

A temporary bridge of this type was placed over the Passaic River a few years ago and was built complete in forty days. The clear opening is 40 feet, the hoisting towers being framed of timber, but the girders are of steel. Adjoining it is 280 feet of pile trestle, the total cost of the whole construction being $12,000.



A Belidor Bridge at Chicago.

A patent was recorded on March 4, 1899, in favor of Mr. Montgomery Waddell for a bascule bridge with trusses counterbalanced by weights attached to the upper panel points and rolling on curved tracks similar to the design invented by Belidor, but differing therefrom by having open web truss supports instead of simple beams.

One of the most recent of this type is that completed in 1908 at Tiverton, over Sakonet River. The original design was made by Mr. Augustus Smith, and was revised and approved by Mr. J. R. Worcester. The road is 32 feet wide with a 5-foot cantilever walk on each side, the central way being proportioned for 40-ton electric cars. The opening span is of the Délille system, with two leaves and a clear water width of 100 feet, and at each side of it is a 70-foot girder which supports the counterweight. There are also masonry approaches 581 and 439 feet long, with concrete arches and earth filling between the spandrel walls. The counterweights are rigidly attached by struts to the moving leaves and instead of separate circular rollers, as on the previous design, the counterweight in this case extends clear across the roadway, being mounted at each end on four-wheeled trucks. Motors are connected directly to the track wheels and ropes are not needed. The moving span is without tail pits and all parts are open for inspection. The steel superstructure weighs 430 tons and the total cost of the whole bridge was $250,000.

Tower Bascules With Vertical Moving Counterweights.—Three different methods of counterbalancing draw-bridge leaves were evolved in France during the first part of the eighteenth century by Messrs. Derché and Poncelet.

The Derché System.—In the Derché system, invented by Captain Derché about 1810, chains from the front end of the moving leaf passed over fixed pulleys on shore, and the

counterweights were suspended over spiral sheaves. As the leaf rose and less weight was required to balance it, the spirals revolved to such a position that the counterweights hung over a smaller radius than when the leaf was down. Derché evolved easy methods for determining the exact form of these spirals, and on the spiral axes he placed sprocket wheels with hand chains, by means of which the leaf was operated. Overhead balance levers of the Dutch portal type were also installed in some cases, so the movement could be affected either by chain or lever. Movable hinged struts bracing back diagonally to the abutments, and revolving in against the shore as the platform was lifted, were sometimes placed beneath the leaves. This method of counterbalancing the leaves in all positions was so simple that it became quite popular in France and other parts of Europe.

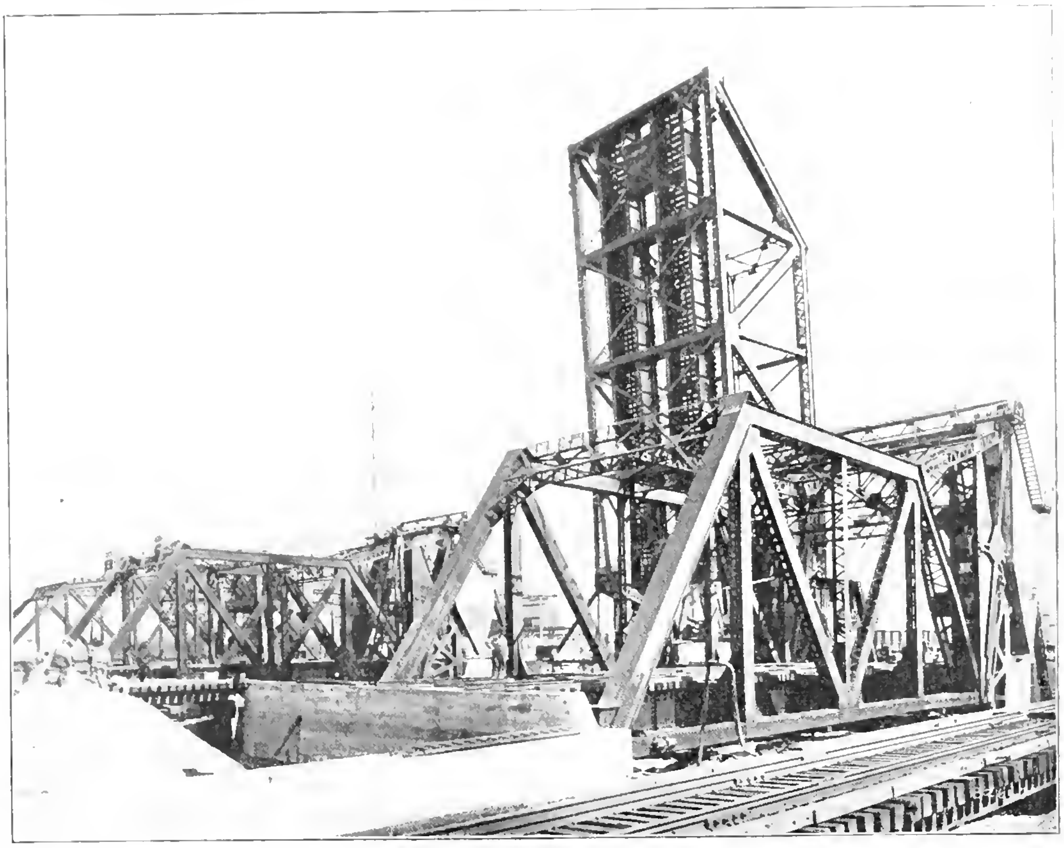
A bridge with varying counterweights had previously been proposed by Colonel Bergére, who intended using weights immersed in water, but his method was not greatly favored.

A modification of the Derché type was used some years ago in San Domingo. At the foot of the shore tower was a conical drum, to the small end of which was attached the balance chain from the outer end of the platform, while to the larger end of the drum was fastened the chain from the counterweight. Two applications of the Derché principle have recently appeared in America, the first of them being proposed in 1901 for the 95th Street bridge at Chicago. The plans showed a double leaf bridge with a clear opening of 140 feet. The leaves act as a three-hinged arch when closed, and are united by centre locks driven by a five-horse-power electric motor. The arch ribs are drawn up by cables passing over two 24-foot drums at the tops of towers, which are 80 feet high, and between these drums and on the same axle are spirals from which the counterweights are suspended. The spiral radius decreases from 12 to 3 feet. The total weight of each leaf is 120 tons.

Another design involving the Derché principle was invented and patented in 1904 by Mr. Wilbur J. Watson. In this design the cables are attached to fixed points on the trusses, and pass around sheaves of the proper diameter to which they are securely fastened, and on which they wind up upon themselves as the bridge rises. The counterweights are carried by chains built up of steel plates and pins. These chains pass around, and are wound from spiral sheaves mounted upon the same shafts as the first-mentioned ones. Chains are used instead of cables for hanging the counterweights because chains can be wound around drums of a smaller diameter. The counterweights are claimed to be less than half of those ordinarily used on bascule bridges, and the stresses in the structure, machinery and foundations are proportionately reduced.

The Poncelet System.—The other two types of bridges with compensating counterweights were invented in France by Poncelet prior to 1840. In one case, the leaves are supported by cables passing over fixed pulleys on shore, and over sheaves behind them, from which counterweights of heavy chain links are suspended, the lower ends of the chains being fastened to the shore structure. As the leaf rises and the chain links descend a greater part of the chain weight is transferred to the lower support, and less to the cables which pass over the sheaves to the bridge. The counterweight is self-acting and extremely simple, and it has, therefore, been extensively used. Small bridges thus equipped can be worked by a sprocket chain and wheel. The principle has been used to some extent in recent moving bridges of other types, as on the Halsted Street vertical lift bridge at Chicago.

A design for counterweight which is a modification of that described above, appeared in 1896 in the competition for a bridge over Newton Creek, the work of J. D. Wilkins and R. W. Creuzbaur. The clear opening of 100 feet was crossed by a single leaf which was drawn up by ropes passing over sheaves on a symmetrical tower on one shore, and it was balanced by a metal box 21 feet long filled with pig iron, and compensated with chain, the whole being described as "the Wilkins system of counterweight." A somewhat similar regulating system was, as previously stated, used on the Halsted Street bridge.



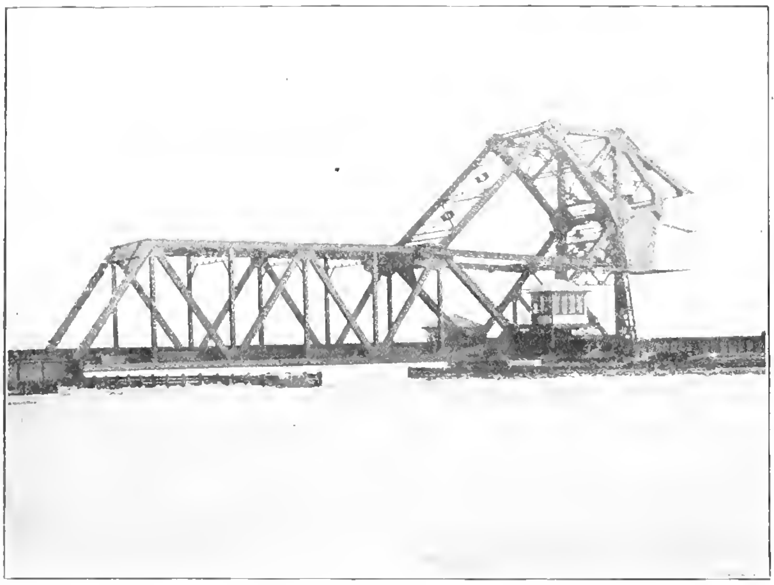
Bridges at Indiana Harbor, Michigan.

Revolving Arch With Bascule Floor.—An unusual design for a bascule bridge appeared at the Newton Creek competition, the work of Mr. W. H. Breithaupt, a Toronto engineer, a patent for which was recorded July 3, 1896. It consisted of movable ribs meeting when closed above the channel centre and forming a three-hinged arch with suspended bascule floor leaves beneath. It was somewhat similar to a bridge previously erected at Liverpool, where the lower bascule leaves are suspended from double swing spans on

each shore, the deck of which is at a higher level. The chief merit of Mr. Breithaupt's design is that, for tugs and small craft the bascule floor only need be raised without opening the arch. The arches and bascule floor had separate counterweights consisting of chains, each link of which weighed two tons.

A patent was granted to Mr. Montgomery Waddell and filed April 6, 1897, for a somewhat similar type of bridge with lenticular or cigar-shaped arch ribs meeting at the centre when closed. The platform, instead of being suspended, as in Mr. Breithaupt's design, was in this case hinged to the arch ribs. Another patent granted to Mr. Waddell at the same time shows double bascule trusses hinged at the foot of the shore towers and supported underneath by diagonal struts bracing back to the abutments.

Suspended Series of Falling Counterweights.—Another system of compensating counterweights was invented by William Burdon and described in the Scientific Canadian of February, 1879. The lifting was accomplished by ropes



Strauss Trunnion Bascule Bridge, Hackensack River, Erie Railroad.

from hydraulic pistons, and the leaves were balanced by cables from their outer end passing over sheaves at the top of shore towers in which a series of weights were suspended, which came to a bearing on the ground as the leaf ascended. A somewhat similar type of small bridge was used many years ago at the Liverpool docks, the chains going down inside the shore columns to the hydraulic machinery below. In 1892, a plan on a larger scale was proposed by Mr. Charles Steiner, of Minneapolis, in which double leaves, each 25 feet long, were used over a 250-foot channel, the leaves being supported by chains passing over pulleys on shore towers and fastened to hydraulic rams. Another bridge at Birkenhead, over the Great Passage at Granaries, carried two tracks of railroad on double leaves over a 30-foot opening. When in their lowered position, the girders were strengthened by hinged struts supported by chains which guided the ends of the struts into sockets on the abutment faces. The bridge was raised by chains passing over pulleys on vertical pillars 10 feet high, set 8½ feet back from the abutment face. It was very light, had no tail end or balance and occupied a very small dock space.

Bridges of this type were brought into active use in America in 1890, when one over the Harlem River was completed for the New York Central Railway, near 135th Street and 4th Avenue. It was designed by Mr. G. H. Thomson, assisted by Mr. J. D. Wilkins. The principle involved is identically the same as that which is so commonly used in crossing gates, which, when open, fold up at each side of the street against their weight cases. The bridge was 106 feet long and 32 feet wide, with four tracks, the two outer ones curving in at the bridge and making it possible for only two trains to cross at one time, notwithstanding the heavy travel of more than five hundred trains daily. Switches were not used. The sheaves at the tower tops were quite unusual, being made of old locomotive driving wheels, 6 feet 10 inches diameter grooved out for the cables. Three years after its completion the bridge was removed and re-erected over the Harlem at Spuyten Duyvil. In 1897 there was a similar one on the Wisconsin Central Railway at Manitowoc, Wis., and another was proposed about the same time by Mr. C. E. Bidell for crossing Newton Creek. The clear opening in the latter case was 150 feet, and towers 112 feet high on each shore support 9-foot drums, over which the cables pass, holding the 65 tons of counterweight in several separate blocks. It was provided with a 36-foot road and 11-foot walks outside the trusses, the whole bridge being supported on cylinder piers. When the leaves were lowered they were to be supported by eye bars from the towers, the bars being hinged at the centre to fold up as the leaf was raised.

One of the last bridges of this kind, completed in 1905, crosses the New Basin Canal at New Orleans. It has an effective span of 70 feet over a 63-foot channel, crossed by through plate girders 9 feet deep, for double track. Towers are 104 feet high, inside of which hang the counterweights in successive blocks weighing 3,000 pounds each. It is operated by a 35-horse-power electric motor, but also has an auxiliary 10-horse-power gasoline engine.

Between the years 1897 and 1900, designs for several bridges of this type were made by I. G. Tyrrell, including those at Elizabeth City, N.C., with a span of 24 feet; Chatham, Mass, with span of 25 feet; Charleston, S.C., with span of 60 feet, and Kennebunk with span of 81 feet. A small one for single track, designed by the writer in December, 1899, had a 21-foot clear opening, and was founded on piles. It was proportioned for light locomotives equal to Cooper's specification E.30, and had hand machinery only. The estimated quantities for superstructure only, without foundation or floor, are:—

Structural steel	20,000 lbs.
Machinery	3,000 lbs.
Counterweight	16,000 lbs.
Total	39,000 lbs.

If the clear opening were increased to 30 feet, the estimated quantities would then be:—

Structural steel	30,000 lbs.
Machinery	3,500 lbs.
Counterweight	24,000 lbs.
Total	57,500 lbs.

A patent was filed February, 1908, in favor of Louis H. Shoemaker, of Sewickley, Pa., for a counterbalanced lift bridge, in which the pull on the cables from the bridge and fixed counterweight is equalized. As the bridge rises, the angle of the cable changes, making a nearly constant pull in the cables from the girders at all times.

Poncelet Bascule System.—This was evolved by M. Poncelet, in France, prior to 1840, and is a modification of the Derché draw. It was revived in 1896 during the Newton

Creek competition by Mr. T. E. Brown, for a double leaf bridge with a clear span of 150 feet. Mr. Brown, four years earlier, submitted a plan for crossing the canal at Duluth, which is said to have been the first important bascule design in America. It had no counterweight, and the estimated cost was $125,000. The towers of the Newton Creek design, standing on each side of the water, were 74 feet high and unsymmetrical, the width of road being 30 feet, with a 9-foot walk outside the trusses at each side, making a total width of 50 feet. The six cables at each side, passing over two 10-foot sheaves made of riveted steel plate, support a permanent counterweight hanging inside the towers, and each span is operated by eight hydraulic rams, the leaves being pushed open by struts connected to the heels of the trusses which swing on trunnions fixed in the tower legs. An unusual feature of the design is, that swinging hinged bents attached to the ends of the leaves gave them a centre bearing under live loads. These bents were to rest on the cast iron caps of submerged piers which could be cleaned of sediment or silt by water pressure from pipes especially laid for this purpose beneath the river bed. Mr. Brown also proposed an alternate plan for disposing of the bents and supporting the leaves by cables from the towers. The estimated cost was:—

Superstructure and machinery	$105,000
Foundations	105,000
Total	$210,000

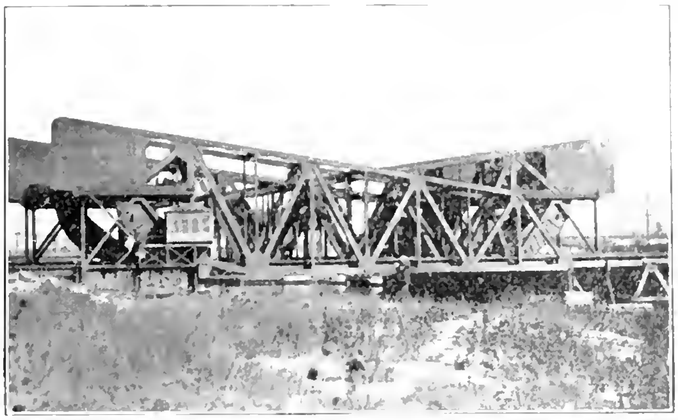
In this design, the tower height could be fixed by the required vertical movement of the counterweight without special reference to the inclination of the lifting cables. But the design with its unsymmetrical towers was complicated. Referring to the various plans which appeared at this time, the Engineering Record, in commenting thereon, rather harshly declared that "the Newton Creek competition has produced an exhibition of more structural ugliness and awkwardness than any other event of its kind in this country." A design somewhat similar to Mr. Brown's was prepared in 1900 for another place, by a structural company in Milwaukee.

The first bridge of the kind completed is at Ohio Street, Buffalo, finished in 1906, with a single leaf 166 feet long and lattice trusses 21 feet deep, over a channel 140 feet wide. One leaf was evidently more economical than two, since it required only one tower, one set of machinery, and one operating house. It replaced an old swing bridge, which was removed when the channel was deepened from 19 to 23 feet. The roadway, 30 feet wide, carries two car tracks, and 7-foot walks project out at each side, making a total width of 44 feet. The span is balanced by twelve plough-steel wire ropes, 2¼-inch diameter, passing over 10-foot cast-steel sheaves (cast in halves) at the top of tower, the two counterweights, each containing 180 tons of cast-iron, moving vertically between guides. The lifting is controlled by hydraulic power from a tank in the tower, under which are girders 52 feet long, and the approach span at the opposite end is 100 feet. Its total cost was:—

Superstructure (including plans and royalties)	$117,700
Foundations	59,300
Total	$177,000

The cables have a heavy bending stress, due to winding over their sheaves, and the breaking load of each one is 190 tons.

The Burel drawbridge, invented prior to 1840, is a modification of that by Poncelet. The counterweight is placed at the extreme end of a 90-degree revolving segment, over which the cables pass when the bridge is in motion. The system has been recently revived and a patent thereon granted February, 1900, to Elmore D. Cummings, of St.



Cambell Avenue Bridge, Chicago.

Paul. It is described as "having a counterweight pivoted to a separate approach framework and connected to the moving leaf by chains which pass under the counterweight framing and over the top chords of the trusses in such a manner that equilibrium is maintained in all positions. The operation is by a rack and pinion on the top chord."

REPORT ON FORESTS.

At the fourth annual meeting of the Commission of Conservation, held at Ottawa January 21st and 22nd, the report of the Committee on Forests was approved, covering recommendations with regard to the following points:

Approving the plan of co-operation in effect between the Board of Railway Commissioners and the Dominion and Provincial Governments for the enforcement of the fire regulations of the board; urging the establishment of a fire-protective service along the Intercolonial and National Transcontinental Railways similar to that provided for in the fire regulations of the Railway Commission; urging the governments of New Brunswick and Nova Scotia to organize separate branches devoted especially to forest fire work and to appoint technically educated provincial foresters as has been done in British Columbia, Ontario, and Quebec; calling attention to the necessity of considering the requirements of brush disposal in the issuance of new licenses and the renewal of old licenses by Dominion and Provincial Governments; approving the organization of co-operative associations of limit holders and the principle of contribution by the Dominion of Provincial Government in proportion to the benefits received; urging the Dominion and Provincial Governments to begin a systematic study of the extent and character of forest resources; emphasizing the necessity for the collection of complete fire statistics; approving co-operation with the government of Ontario in an examination of forest conditions west of Sudbury and south of the Clay Belt; approving the proposed extension of the Dominion Forest Reserves and the establishment of a game preserve in the southern portion of the Rocky Mountains Forest Reserve and in southeastern British Columbia adjoining the Glacier National Park; urging that all appointments in the forest services of the Dominion and Provincial Governments should be based solely on capability and experience; urging the government of Ontario to undertake a systematic classification in the Clay Belt in advance of settlement to the end that settlement may be properly directed, and that non-agricultural lands may be reserved from settlement and entry.

REPAIR AND MAINTENANCE OF ROADS.*

By Dr. L. I. Hewes.†

The primary defect in road repair and maintenance to-day is lack of business management. The management of road construction is slowly improving, but repair and maintenance continue neglected. There is a certain enthusiasm and interest about new work which is entirely lacking for repair and maintenance operations. It is now well recognized, however, that no system of roads will remain a good system unless continuously cared for.

It is necessary to distinguish between repair and maintenance. When a road is finished, traffic and the elements act continuously to deteriorate it, and will ultimately destroy it. To oppose such deterioration, maintenance equally continuous is required. If maintenance is neglected the best roads will very soon require repair and longer neglect will even require reconstruction. It has been customary for a long time to classify repair as maintenance. It is a natural mistake in view of the fact that, generally speaking, roads on this continent have not been continuously maintained and therefore if maintenance is referred to, it necessarily signifies repair.

Under the organization which prevails throughout Canada and the United States, town and county roads are largely in charge of local officials elected at short intervals. Road management constitutes, as a rule, only a part of a miscellaneous list of duties. Consequently local officials are not elected because of their skill in road making. The typical road official has abundant confidence in his ability and usually proceeds to try out his ideas at the expense of the community. He has his own definition of gravel, crown, grade, etc., and usually has spent considerable money before he is willing to seek advice; and then it is time for electing a new man. Now, any system in business where an executive officer was dismissed as fast as he learned his duties would be unhesitatingly condemned. Why do we continue to use such a system on our highways.

The difficulty is largely because the local civil unit for highway purposes is too small. Too small because the annual appropriations for highways do not warrant the employment of skilled supervision; too small because with the permanent practice of rotation in office the annual appropriation is handled by each official as *his* appropriation, without reference to what has preceded or what is to follow. Too small because the experience in road construction and maintenance does not cover a wide enough range to supply information which already exists beyond the borders of the local community. The remedy for this condition, which so universally prevails, is co-operation in some of its various forms. A possible form of co-operation is for townships to collectively organize road districts and hire a salaried road engineer. Another possible form is to delegate more authority over local roads to county officials and to require a high-class county engineer. A still more effective form is to invite co-operation from the state or province, even in the matters of township roads, as well as in county roads and inter-county roads. It has been done in the State of New York.

You will observe that all of these methods suggested involve more centralization in the matter of roads. If there is objection to such centralization, the answer must be that there must then continue a "road problem," for an actual study of the scant records that have been kept on the cost and method of earth road work always reveals the startling fact that enormous sums of money have already been spent under the old system without visible improvement in the roads. I do not hesitate to condemn the use of statute labor upon highways. It has never proved effective. There are several fundamental objections to its use. First, under the statute labor system, work upon the roads cannot be, in any sense, continuous. Neither can it be applied "in point of time." Second, the attitude of freemen toward such work is careless and indifferent, and the days of working out the taxes are too often regarded as more or less of a jollification period. Statute labor is not economy even for those who advocate is strongly. For those who advocate it strongly are the residents who see in the custom an opportunity to avoid cash payments and to discharge a duty to the community with a minimum of effort. Now, the dwellers along the road are the ones to use the roads, and in proportion as the repair and maintenance of their roads is poor, so is the transportation burden per ton mile of useful produce increased. Those who advocate statute labor in preference to cash taxes simply shift the payment of a road tax to the payment of a mud tax. The road tax is a definite sum of cash, the mud tax has the never-ending invisible burden on the cost of hauling.

Let us consider, then, the repair and maintenance of a typical well organized county road system. In the first place, there should be a map of the county showing plainly all the roads within its borders. These roads should be classified. A possible classification is market roads, through roads and neighborhood roads. Necessarily many market roads will also be through roads and usually every through road is in part a market road. When the roads have been classified according to their service, there should be indicated the nature of construction on the already improved portions in each class. By consulting records, the average annual appropriations for all road and bridge purposes for a series of years may be determined. It will usually be found that some of this money has been spent for the new work, but that a large percentage of it must go for annual repairs. The county highway engineer or other highway engineer in charge of the road system must then adopt a financial plan, not for one or two years, but such a plan as will, within a series of years, result in a general betterment of the highways under his jurisdiction. A certain large percentage of the roads will receive a minimum of expenditure proportioned according to their importance. These roads will, many of them, be neighborhood roads which serve, in many instances, but one or two families. A plan of improvement system established for all improved roads and especially for the important roads which must wait for improvement.

The order of improvement to the relatively small percentage of most used roads should be definitely determined, and the type of improvement should be carefully planned. In making such plans, it must be understood that the first mile of any highway radiating from a market centre receives an annual traffic many times greater than a mile of the same road which is six or seven miles away from the market. Therefore, the type of improved surface adopted near the town must necessarily be more expensive than that adopted on the outlying mileage. A great deal of permanent improvement may be brought about on earth roads by the expenditure of the money which is usually classified under annual repairs. The engineer should first determine the existing profile of such roads and establish a grade line toward which some work may be done each season. The necessary improvement of the culverts, such as replacing wooden and other cheap construction by more durable construction such as concrete, should be planned so that some permanent

* Paper presented to Ontario Good Roads Association meeting, Toronto, February, 1913.

† Director, Maintenance Division, U.S. Office of Public Roads, Washington, D.C.

piece of work may be done each year and the whole effort should be to produce ultimately a road which may be adapted to this service, and which shall require low annual repair and maintenance charge. You must see that no such scheme of work can be planned and carried out by any road official who sees only the expenditures of one year ahead.

To get a little nearer to details, there must be begun a systematic set of highway accounts. All operations of repair and maintenance, as well as construction, should be classified as grading, ditching, repairing culverts, dragging, etc., and the unit costs of the various items must be obtainable from the records. To accomplish such a result, distributing tables may be printed on the backs of warrants and vouchers for labor paid. A great defect in maintenance and in repair has been the unintelligent management of materials and machinery. If a macadam road is to be maintained, there must be a supply of No. 2 stone stacked in considerable quantity at intervals along the road. The hauling of this material should be done at the most economical season of the year, and it should be continuously available for small repairs. The same applies to gravel. A great many roads may be constructed successfully and maintained as gravel roads with good results. For this purpose the location of the sources of supply of gravel and gravel pits should be plotted on the road map and a record of the quantity in each pit kept. Very frequently gravel is hauled necessarily great distances for various insufficient reasons. Too often the owner of the gravel pit is also managing some of the roads and may prefer to haul a mile or two from his pit when there exists a supply of good gravel within a quarter of a mile of his job. There is frequently, however, good gravel handy to work, but which has never been discovered or developed. It will pay to make a most careful investigation of the source of gravel supply along every road.

With reference to the repair of earth roads, the custom of scraping sod and refuse of all kinds into the road centre with a scraping grader cannot be too severely condemned. It is a universal cause of bad roads and waste of highway funds. In repairing an earth road with a scraping grader, the sod may first be scraped off and carted away or the sod may be raked off or picked out with forks and carted away, but never should sod or rotten leaves or manure or any organic substance be placed on the road. The operations of the road grader have been positively damaging in some cases. Many country roads have gutters that are too far from the travelled way and the road supervisor runs the scraping grader a little outside of the wheel tracks to form a new gutter which wanders in and out and up and down and has no outlet. The cost of operating a scraping grader with from two to eight horses attached is very great, and unless very effectively managed is a source of tremendous waste. Where new gutters must be formed, lines must be run before work is commenced, and broad shallow outlets should be constructed through the turf at all low points and all intermediate points on hillsides. Frequently the repair operations with a road grader can best be accomplished by scraping old material off the road toward the gutter and carting it entirely away. A great defect in most country roads is a high shoulder just outside the wheel track. The road grader can be used effectively to lower the shoulder by beginning at the wheel track and working in successive trips toward the gutter. The earth can then be moved to the centre of the road more quickly and without moving a constantly increasing mass. Very frequently the blade of the road scraper is run too deep at the gutter and not deep enough upon the shoulder.

When an earth road has been put in repair, it can be maintained by the road drag. The original form of the road drag was a split-log drag made from the split halves of a six to eight-foot log, six to eight inches in diameter. The two halves of the log are placed face forward and are set two and a half feet apart and at an angle of 45 degrees to the axis of the road. They are suitably braced and supplied with double-trees. In using the split-log drag, two horses are usually needed. Dragging begins at the outside edge or the gutter line of the earth road and proceeds toward the centre. The effect of the drag is to pair off ruts and move a small quantity of earth toward the centre of the road. It also has the capacity to puddle the surface material and form more or less impervious layers which prevent moisture from soaking into the roadbed. To drag a road twenty-four feet wide will require three round trips. A team of horses can draw a drag in ten hours about twenty-four miles, so that with three round trips, about four miles of road can be dragged in a day. This is probably the maximum. On steep grades or with unfavorable conditions, such as irregular gutters or stones in the road, the performance will be less. The minimum cost, figured on a four-mile basis, depends on the price of a man and team; at $4 a day, a complete dragging for three round trips is $1 per mile. In the experimental work by the United States Office of Public Roads in Alexandria County, Virginia, the cost of dragging has been about $1.25 per mile of three round trips.

The first year of dragging an earth road will require a greater number of trips than in subsequent years. Possibly 24 draggings will be required. As the road gets harder under continued dragging and traffic, fewer trips are needed. Important problems to determine immediately are how to establish the dragging system. Probably the best way will be, for the present, for road officials to contract with men who live along roads to drag sections from two to four miles in length. The dragging should be done after every rain and the section men may be required to fill out and forward to the supervisor a post card for each day of dragging. As time goes on, it may be possible for many communities to combine the road patrol and dragging system. This will require the continuous employment of men for probably seven months in the year. If they are paid $45 per month with the understanding that they are to do all dragging, when necessary, the annual cost will be $31.50 per mile on a ten-mile section. This is not an excessive cost per mile. It would no doubt pay to establish such a system in those counties which are spending around $40 per mile on any considerable mileage in the community. The presence of the patrolman during storms to prevent erosion and keep drainage in working order is a great permanent benefit to the road. In the experiment by the United States Office of Public Roads, as above referred to, about 43 per cent. of the patrolman's time was devoted to repairing, cleaning and improving ditches and under-drains and 23 per cent. to dragging. Whatever system of dragging or continuous maintenance is adopted, and the continuous maintenance is the best system, there must be competent inspection and daily reports to the inspector.

On the continent of Europe, the road men are frequently supplied with written instructions covering the slightest detail of their work. There is no reason why such a system could not be adopted on this continent. There is need for written instructions covering a great variety of details; for example, the care of the road at driveway entrances, particularly on hill-sides, is extremely imperative to prevent wash from adjacent lands. This is also true of road intersections.

With reference to the method of maintenance of macadam, gravel and bituminous macadam roads, there is much to be said. Written instructions should be issued covering all such points as the selection of stone, the preparation of worn holes and ruts to receive repair material, sweeping, scouring and picking up of the old road, etc. Wherever a

roller is present there should be instructions to roll all macadam roads in the spring as soon as the frost is out. The management of the hauling of gravel and broken stone, the balancing of men and teams, offers a great opportunity for economy and detailed instructions on such matters are not superfluous.

It is scarcely necessary to add to what has been said above that the repair and maintenance of our highways is a business which requires trained men for its management and skilled workmen for its performance. There is no need to argue and waste oratory over the road question longer. We know it needs business management and we know that it costs an excessive amount of money under the old system. Furthermore, we know that the roads do continue poor. Happily, it has been found that all road work responds amazingly to organization and skilled supervision, nor is it necessary for a general election or overhauling of official positions to make a beginning in the improvement of repair and maintenance operations upon our highways.

FIRE CLAY TESTS.*

The term "fire clay" as it is generally interpreted has a very indefinite and elastic meaning. Usually it is applied to any clay which may be made up into wares that will withstand high temperature. This might mean any degree of heat from that attained in an open fire-place to that reached in a furnace for ore smelting. Obviously a clay suitable under the first set of conditions would not, in all probabilities, be suitable under the second. Fire-clays are frequently found associated with coal seams and in consequence miners invariably call any clay so associated a fire clay. In general this is far from the truth. The clay worker, at least, must have a more definite conception of the meaning of the term.

It is commonly accepted that the dividing line between refractory and non-refractory clays, as regards their temperatures of fusion, lies at or near 1,650 degrees centigrade, although this cannot be taken as a safe criterion for classifying refractories. It can be safely said, however, that very few No. 1 fire brick are made from clays fusing below this point. Since a high tension fusion point is the prime essential, its determination might well be made the first preliminary test.

The clay to be tested is moulded into a small "trial" the size and shape of a Seger cone (a tetrahedron or triangular pyramid about two inches high and measuring about half an inch at the base. This is placed in a vertical position on a fireclay slab, lowered into a suitable furnace, and the temperature gradually raised until fusion has proceeded to such an extent that the sharp edges of the cone have assumed a rounded appearance and the tip has fallen over until it touches the base. The temperature at this point is recorded as the temperature of fusion.

At first this might appear as a very reliable index to the character of a clay, but upon carefully considering the facts this is found not to be the case. Clays, being mixtures of minerals rather than definite chemical compounds, have no well defined melting points. The change from the solid to the viscous state is very gradual, often extending over a period of several hundred degrees. If two clays are taken whose cones show the same temperature of fusion, it may occur that if an appreciable load be applied to each at temperatures approaching their fusion points, great difference will be noted in their failure temperatures. This is due to the difference in their periods of softening; the one having the longer softening period failing first.

To this end, a test of fire brick under load at high temperatures has been devised by Bleininger and Brown at the Pittsburg Testing Laboratory. The furnace used for this work was of special design and is described by them in detail in Vol. XII, transactions A. C. S. It is fired by means of natural gas and compressed air and it is possible to bring the temperature up to 1,350 degrees Centigrade in about five hours. The load is applied to the brick by a lever outside the furnace and is carried to the brick through a high-grade fire clay bar acting as a column. The lever is fitted with adjusting bolts by means of which it can at all times be kept in a horizontal position. The movement of the lever can be observed by the operator and is an index to the action of the brick under test. Their final recommendation is that the brick be placed on end under a load of 50 pounds per sq. in., and subjected to a temperature of 1,350 degrees Centigrade for one hour. They further recommend that a one-pound fire brick should show no other marked deformation than a shortening of not to exceed one inch in the total original length of nine inches.

Some objections might be raised to this test on the ground that the time factor at high temperature figures prominently in the failure of fire brick and that in this case the specimen is held at the maximum temperature for only one hour. On the whole, however, the test relatively approximates actual conditions of use and gives such consistent results that it is likely to become, in time, a standard test for fire brick.

The furnace used for making the actual fusions are of several different types. The "Carbon Resistance Furnace" is probably the most convenient and satisfactory of those in use. It is described by Coggeshall and Bleininger in Vol. X. Trans. A. C. S. The casing is made from a high-grade fire clay and is supported on a wrought iron plate. A wrought iron ring and the crucible complete the list of parts. An annular space between the crucible and casing is packed with carbon; a grade known commercially as "Electric Furnace Carbon." The electrical connections are made through a supporting plate below and a ring above. The heat is generated by the resistance of the carbon to the flow of current. The current from the power line is stepped down through a suitable transformer so that it is available at five volt intervals from twenty to seventy volts. With this apparatus it is possible to get sufficiently high temperatures to fuse almost any clay. With the one in use in the Ceramics Laboratory of the Iowa State College, temperatures of over 3,200 degrees Fahr. have been obtained and this limit was determined only by the failure of the crucible by melting.

Methods for the testing of fire clays and fire clay products have not yet been standardized but considering the progress that is being made in Ceramics work, it should not be long before methods for systematic examination are available.

* From the Iowa Engineer, by M. F. Beecher, B.S., assistant in Ceramics, Engineering Experiment Station, Ames, Iowa.

DOMINION STEEL CORPORATION.

The nail plant of the Dominion Steel Corporation at Sydney is being steadily enlarged and although the company has been making nails on a commercial scale only a few months it is already becoming a large factor in the market.

A galvanizing plant of modern type is in operation. The only thing needed to complete it is the installation of the permanent power

The company's wire mill is equipped not only to provide wire for the nail mill and galvanizing plant, but wire for sale as well, including wire already drawn to be made into nails. The new annealing department to supply that part of the wire market is being rapidly pushed forward to completion.

WATER FRICTION IN WROUGHT IRON PIPE.*

Due to widely varying tables that appear in different handbooks and the necessity of elaborate interpolation to make them usable, a great deal of time is generally wasted in solving problems in which friction of water in pipes is a factor. Ira N. Evans (Power, July 9, 1912), has taken six of the best formulas for the friction of water in commercial wrought-iron pipe, together with the results of several tests, and compared them in tabular form.

The following were the principal formulas used by Mr. Evans in obtaining his average:

(1) Williams & Hazen formula:

$$V = cr^{0.63} \left(\frac{h}{l}\right)^{0.54} 0.001^{-0.04}$$

V = Velocity in feet per second;
c = Constant varying with condition of the pipe;
r = Hydraulic radius = $\frac{d}{4}$ in feet;
h = Friction head;
l = Length of pipe in feet.

The constant 120 gave results for most of the sizes higher than the average, while the factor 125 would give results checking closely with the average.

(2) Darcy's formula:

$$h = 0.003732\ l\ V^2 \frac{D + 1}{D^2}$$

D = Diameter in inches.

This formula gives values higher than the average.

(3) Meier's formula:

$$h = 0.0038\ l \frac{V^{1.86}}{D^{1.25}}$$

D = Diameter in feet.

(4) Harrison's formula:

$$h = 0.00375\ l \frac{V^2}{D}$$

D = Diameter in inches.

The results from this formula are below the average for pipe up to 6 in. in diameter.

(5) Fanning's formula:

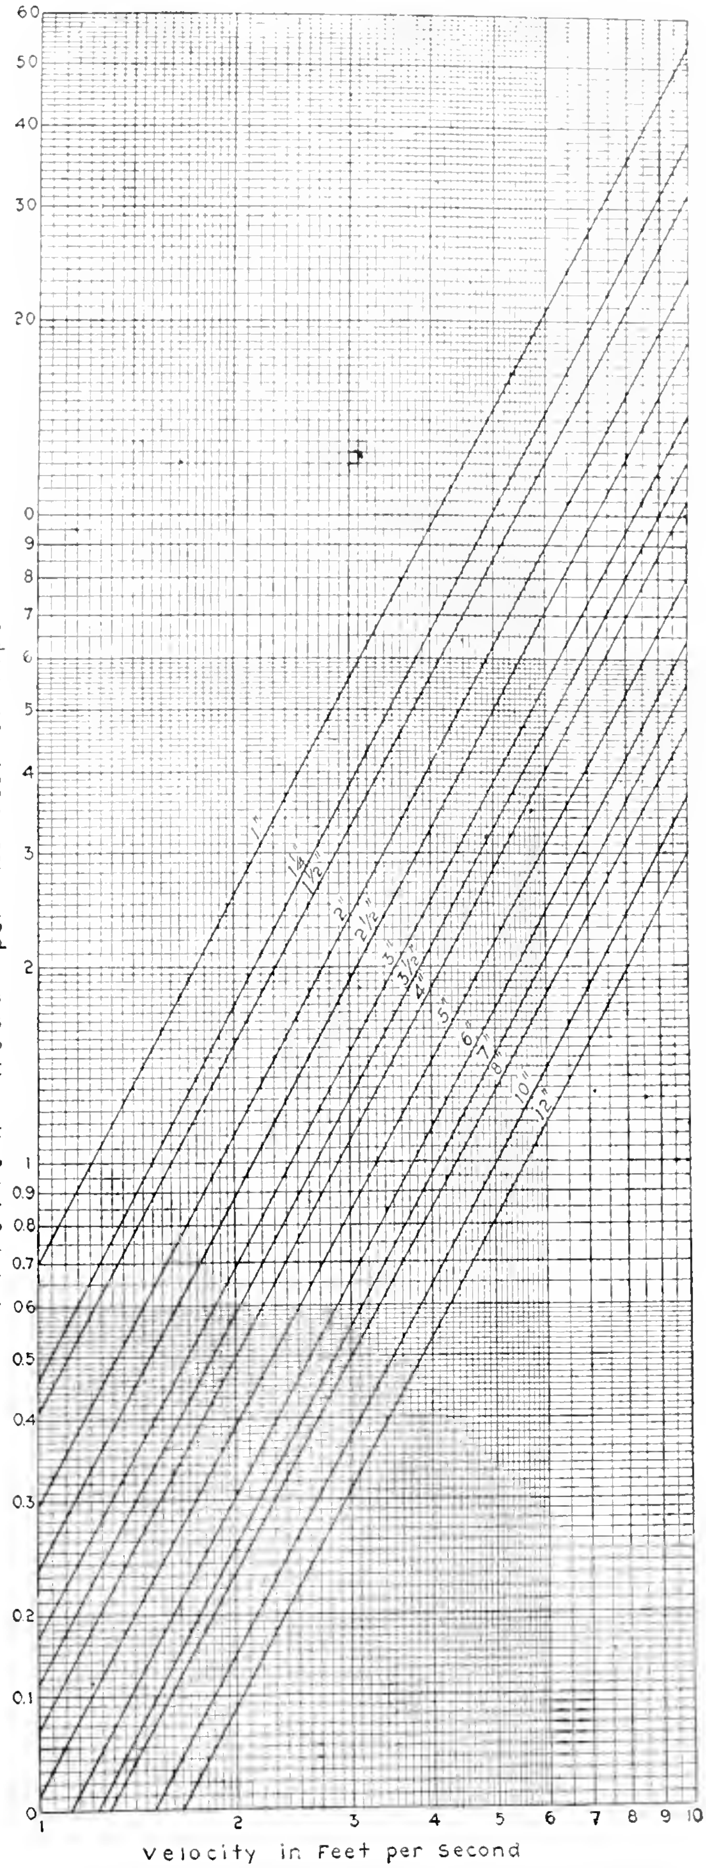
$$h = f \frac{l\ V^2}{d\ 2\ g}$$

The constant f varies for each change in size and velocity. This formula follows the average closely and gives results more consistent than the others except that of Williams & Hazen.

(6) Serginsky's formula, compiled from the latest German authorities, was also used. It gives results above the average for small sizes and below the average for large sizes.

The average values derived by Mr. Evans, mainly by the foregoing formulas, have been plotted by W. L. Durand, on logarithmic paper, as shown in the accompanying curves (Power, Oct. 29, 1912). All equations of the general form $y = B x^n$ will plot at straight lines. Several of the formulas are

* Taken from Engineering and Mining Journal, Vol. 94, No. 23.



FRICTION HEAD IN PIPES 1 TO 12 IN. IN DIAMETER

of this form, and those that are not vary from a straight line to only a slight extent. The average values then may safely be represented by a straight line, as the greatest variation will be much less than the difference between any two values that make up the average.

The method of using these curves is self-evident, there being three variables and in any problem containing two of them the third can be found immediately from the chart. If only one variable is known, several values of one of the other two may be assumed and the corresponding values of the third found from the chart. The values that seem to best fit the problem may then be chosen.

The chart is plotted with velocities from 1 to 10 ft. per sec. as abscissas and friction head per 100 ft. from 0.1 ft. to 100 ft. as ordinates. Each curve is for a definite pipe size as indicated, and with a little variation, all the way through for velocities of 1 ft. per sec., the chart shows values practically identical with the averages in Mr. Evans' table.

For example, take a 3-in. pipe with a velocity of flow of 6 ft. per sec., the friction head per 100 ft. of pipe would be 5.45 ft. To produce a drop in head of 2 ft. in 100 ft. of 5-in. pipe would require a velocity of 4.7 per second.

ROAD CONSTRUCTION COURSE AT UNIVERSITY OF TORONTO.*

By A. T. Laing, B.A.Sc.†

Mr. Chairman,—I appreciate very highly the time given on your programme in order to make a statement regarding the attitude of the University toward the movement for better roads, and to tell you of what we are attempting in the way of training men for the duties and responsibilities of highway engineers.

For some years Dean Galbraith, who has given practically his whole life to the training of young men to meet the varied needs and ever increasing demands of this rapidly developing country, has felt that something special should be done to promote this important branch of engineering, and I am glad to be able to tell you that a beginning has been made.

That a technical course of instruction is of great importance in this connection must be admitted by all. There is perhaps no line of engineering work in which the demands are so varied and which require a wider range of knowledge and experience. Called upon as the highway engineer is to deal with constantly changing physical conditions and a varied supply of materials of construction, it is highly important that he should be thoroughly familiar with the fundamental sciences and their application.

He should know how to make surveys, plans and profiles,

Hydraulics.
Strength of materials.
Machinery.
Bridge design.
Masonry and concrete.
Geology.
Chemistry.
Structure of earth crest.
Laboratory methods.
Interpretation of reports.

*Address to Ontario Good Roads Association held Feb. 27th, 1913.

†Secretary University of Toronto.

Now, it is not the intention to establish a four-year course in highway engineering, but to make it a part of the final year in civil engineering. We have started by giving a lecture course in roads, pavements, maintenance, construction, and a laboratory course in the examination of materials, both in road metals and bituminous materials. But we do not expect by this means alone to turn out highway engineers. Superadded to all the instruction that can be given must be a wide experience, and here is where, I trust, this Association and the University may be able to co-operate.

DEFECTIVE CULVERT RECONSTRUCTION.*

By Mr. W. H. Mills.

A defective culvert at Killyman, on the Great Northern Railway, Ireland, was about 160 feet long and was surmounted by an embankment 50 feet in height. It was properly placed in the lowest point in a ravine, and afforded the only outlet for streams and surface water which gathers on the higher side of the railroad.

After carefully considering the many difficulties which arose, a cast-iron tubular culvert was decided on, the system being somewhat similar to the "Two Penny Tube" in London, only it was cut through compact earth, whereas in the Killyman tube the excavation was through loose ground of a railway embankment 50 feet high, consisting of tipped clay, boulders, roots of trees, etc.

The cast-iron tubular culvert was circular in section, with an internal diameter of 10 feet, the outer shell being 1⅛ inches in thickness. There were 91 rings, making a total length of 159 feet 3 inches. Each ring was 1 foot 9 inches wide, and consisted of six large segments, and one small segment, or key-piece, 10 inches long, at the top. These segments were all bolted together with ⅞-inch bolts and washers, placed at about 9-inch centres in the vertical direction, and at about 6½-inch centres in the horizontal direction. All butting surfaces of the castings, both vertical and horizontal, were machined perfectly true, and were thickly coated with white lead as they were bolted together during the progress of the work. To guard against any compression at the crown, which might be caused by the loose or made ground of the embankment overhead, transverse tie rods, ⅞-inch in diameter, and about 7 feet 5 inches long, were bolted to the upper joints of every third ring.

When the 159 feet 3 inches length of cast-iron tube was fixed in position, and bolted together, the lower half of the circumference was lined for the entire length with a half brick (4½ inches) lining of hard brick laid in cement. For 7 feet in length at each end of the culvert the half brick lining was continued all round the inside circumference. A strong masonry face wall and wing walls were built at each end, with large pitching stone invert between the wing walls.

It is interesting to note the comparison of weights. The cast-iron culvert, when taken full of water, weighs 137 tons less than the mass of earthwork which it replaced, and so, instead of an increased weight on the soft surface ground, there is a very considerable diminution. And we must also remember that the culvert, which weighs 511 tons when at its fullest capacity, is never more than one-third full when in its normal condition.

The total cost of the work was $8,500, and proved a perfect success, as work was carried on without hampering the railroad schedule in the least.

*Given in an address before the Institute of Civil Engineers, Ireland.

REPORT TO CITY OF OTTAWA ON SOURCE OF WATER SUPPLY.

The city of Ottawa lately engaged Sir Alexander Binnie and Dr. C. A. Houston as the most capable experts on water supply in Great Britain, to examine into and report to the city on a suitable water supply. The preliminary report of these engineers has lately come to hand and is published herewith. A feature of the report, outside their condemnation of the Ottawa River as the best source of supply, is their calculation that about seventy-five per cent. of the water at present pumped for the city is wasted.

"1. The Ottawa River, in our opinion, is unfit for domestic use in its present unpurified state. Moving the intake higher up the river might improve matters, but would not alter our settled conviction that this source of supply is unsafe in the absence of an approved process of purification. We are convinced that the up-river population is likely to increase rather than to decrease and despite all arguments to the contrary, we remain unconvinced that any rules and regulations can so control pollution in the future as to render the Ottawa River safe for domestic use in its unpurified state. To eliminate the chief risks of these pollutions would entail the construction of intercepting sewers on both banks of the river for many miles above the town at an enormous cost, nor would the fulfilment of this project completely remove our objections to this source of supply.

Must Use Chemicals.

"2. Apart from its liability to sudden accidental pollution of a specific sort, the Ottawa River water is highly colored and it would be a physical impossibility to render such a supply satisfactory without the aid of chemicals. Apart from the merits of the question we recognize that the use of chemicals is repugnant to a large proportion of the citizens of Ottawa.

Waste of Water.

"3. Our difficulties in pronouncing on a permanent source of supply have been greatly increased owing to the apparent consumption of water per head of the population being vastly in excess of all reasonable requirements. The system of distribution obviously requires a thorough investigation and the gross wastage of water not attributable to the consumer should receive immediate attention. At present the wastage would appear to amount to 75 per cent. of the total quantity pumped. In addition, we are strongly of the opinion that the climatic or other local conditions afford an insufficient excuse for any reckless waste of water on the part of consumers. It is essential to recognize that the supply of water per head of the population, hugely in excess of actual requirements, may involve the rejection on financial grounds of new schemes of water supply which otherwise appear to be eminently well suited for the needs of the city.

Lake Water Sources.

"4. In considering schemes for a permanent supply we have ruled out unpurified river water altogether and have contrasted the lake sources of supply with Ottawa River water after efficient purification.

"5. We have arrived at the conclusion that there is a bountiful supply of clear and wholesome lake water available for the needs of Ottawa for many years to come.

"6. Subject to the engineering difficulties of bringing lake water to Ottawa not proving financially too onerous a burden to be borne, and assuming that the drainage area chosen for the purpose would be protected from all sources of human pollution. We have finally decided to recommend the ultimate abandonment of the Ottawa River as a source of supply and to advocate the choice of a virgin lake water.

"7. It is absolutely impossible for us at this stage to discuss ways and means or the precise localization of the northern lake or lakes at present contemplated for water works use and so we have contented ourselves with dealing with general principles. We propose, however, to institute such further inquiries as will enable us to make specific recommendations as soon as is reasonably practicable.

"8. We consider that the present is a golden opportunity for securing for the Capital of the Dominion an unimpeachable source of water supply and of providing for the city without any form of treatment a water neither too hard nor unduly soft and of a bright, clear and transparent appearance.

Temporary Precautions.

"9. Until this great work can be accomplished it is necessary to adopt certain remedial measures and we suggest:—

"(a) That the water in the pipe line between the intake and pumping station should be kept uniformly under pressure.

"(b) That a sedimentation basin should be constructed at a cost which we estimate should not exceed $17,000 by connecting the piers at the intake with the high land on Lemieux Island.

"(c) That the double chlorination treatment now in operation should be stopped and a single treatment of the water as it enters the basin substituted for it. This, in our opinion, would enable the present dose to be reduced or, if the same dose were retained, the treatment would be rendered much more satisfactory than is the case at present.

"(d) That steps should at once be taken to reduce the extravagant rate of consumption per head of the population.

"10. We desire to point out that it is not our function to deal with health matters in the city, but it is obvious that provision of a pure water supply is only one of the steps necessary to secure the safety of the people of Ottawa from undue incidence of preventable diseases.

"In conclusion, we desire to place on record our appreciation of the courteous manner in which the mayor, his colleagues and various officers of the corporation have assisted us in our investigation. (Signed) ALEX. R. BINNIE, A. C. HOUSTON.

"February 10, 1913.

ONTARIO'S PIG IRON PRODUCTION

Ontario's iron and steel industries have received considerable attention since the intention of the United States Steel Corporation to build a plant to cost $20,000,000 at Sandwich, Ontario, was made public. It is probable that the corporation will erect a number of blast furnaces in addition to wire, rail, structural and bar mills.

At present there are nine blast furnaces in Ontario for the production of pig iron. The Algoma Steel Company, at Sault Ste. Marie, has three, the Canada Iron Corporation, Midland, two; the Steel Company of Canada, Hamilton, two, and the Atikokan Iron Company, Port Arthur, and the Standard Chemical Company, Deseronto, one each, reports Mr. T. W. Gibson, deputy minister of mines in the 21st annual report of the bureau of mines. In all, these plants turned out 526,610 tons of pig iron, valued at $7,716,314, an average of $14.65 per ton.

Much the greater part of the steel output of the Algoma Steel Company is rolled into "standard tee" rails, of which the production last year was 243,703 tons, the remainder, 24,617 tons, being in the form of merchant bars, tie plates, angle splice bars, light rails, bolts and nuts.

RAILWAY STATISTICS.

Statistics of steam railways, prepared by the Deputy Minister of Railways and Canals, have lately come to hand and are published below.

Railway Capital.

During the year ended June 30th last, $21,251,664 was added to the stock liability of railways, and $38,996,661 on account of funded debt—representing a total addition of $60,248,325. This increase over 1911 brought the total capital liability up to $1,588,937,526.

The facts with respect to capital liability in 1911 and 1912, for purposes of comparison, are as follows:—

Capital.	1911.	1912.	Increase.
Stocks	$ 749,207,687	$ 770,459,351	$21,251,664
Funded debt	779,481,514	818,478,175	38,996,661
Total	$1,528,689,201	$1,588,937,526	$60,248,325

It will be observed that, with double the operating mileage added in 1912, the amount of capital liability was slightly more than half the increase for 1911. This is explained by (1) market conditions, and (2) the issue of stocks and bonds prior to the completion of line mileage. In other words, the obligation is incurred before track mileage can be officially recorded.

The funded debt of railways was, in 1910, 1911 and 1912, distributed under the following heads:—

Funded debt.	1910.	1911.	1912.
Bonds	$696,677,305	$732,693,760	$772,532,108
Miscellaneous obligations	8,365,077	13,079,015	12,608,718
Income bonds	5,036,546	20,036,546	17,119,466
Equipment trust obligations	12,661,372	13,672,193	16,217,883
Total	$722,740,300	$779,481,514	$818,478,175

If the total capital liability of $1,588,937,526, as given above be divided by the 26,727 miles of operating line shown on a preceding page, the result would be $59,454 per mile of line. It would be quite misleading, however, to make such a calculation. Neither the divisor nor the dividend is correct. The mileage, for example, includes Government-owned and operated lines, to which no capital liability attaches. On the other hand, the capital figures embrace the liability of unfinished lines, such as the Grand Trunk Pacific, which do not appear in the mileage column. The deductions under this head amount to $134,321,020. Then there is considerable duplication. It has not been practicable to ascertain the exact amount thereof, created chiefly by the issue of stocks and bonds for the purchase or control of smaller roads by the larger, but it is known to be not less than $210,000,000. Joining these two sums, and subtracting the total from the $1,588,937,526 already indicated, the remainder is $1,244,616,506. For immediate statistical purposes that might be regarded as the proper capital liability of Canadian railways.

The elimination of Government-owned lines, and such other lines as should not figure in the mileage column, reduces the total to 24,485. Using these factors, it will be seen that the capital liability of railways in Canada amounts to $50,832 per mile. This is a relatively low figure

The mileage, capital cost, and cost per mile of Government-owned and operated railways are given in the following table:—

Government lines.	Miles of line.	Capital cost.	Cost per mile.
Intercolonial	1,463	$94,746,391	$64,761
Prince Edward Island	269	8,687,727	32,296
Temiskaming and Northern Ontario	302	17,665,500	58,495
New Brunswick Coal and Railway	58	1,936,600	33,398

Following is a table showing the facts with respect to the capital liability of Canadian railways since 1910:—

Year.	Stocks.	Funded debt.	Total.
1910	$687,557,387	$722,740,300	$1,410,297,687
1911	749,207,687	779,481,514	1,528,689,201
1912	770,459,351	818,478,175	1,588,937,526

The relationship of dividends and net earnings to share capital during the past three years is shown in the following tables:—

Year.	Dividends paid.	Share capital.	Per cent.
1910	$21,747,914	$687,557,387	3.16
1911	30,577,740	749,207,687	4.08
1912	31,164,791	770,459,351	4.04

Year.	Net earnings.	Share capital.	Per cent.
1910	$53,550,777	$687,557,387	7.78
1911	57,698,709	749,207,687	7.70
1912	68,677,213	770,459,351	8.91

Of the foregoing payment of dividends, $18,487,000 was paid in common stock, and $12,677,791.31 on preferred stock.

Aid to Railways.

During the year $5,892,818.34 was given in cash as aid to railways. This sum includes $4,994,416.34 paid to the Grand Trunk Pacific under the Implement Clause of the agreement between the Dominion Government and that company. That clause provides that Government shall make up the difference between the amount realized on certain bonds and their par value. This is not exactly a subsidy; but there can be no question as to the propriety of classifying such a payment as aid. The whole amount of aid in cash for the year was made up as follows:—

By the Dominion	$5,858,163.34
By the Province	26,155.00
By municipalities	8,500.00
Total	$5,892,818.34

A discrepancy appears as between the aid given by Provinces in the table next succeeding and the table on a later page. It has arisen through defective records between the years 1875 and 1890, which cannot now be corrected: so both statements are published.

Following is an analysis of the cash subsidies paid by the various Provinces since 1910:—

Year.	Ontario.	Quebec.	Nova Scotia.	New Brunswick.
1910	$9,198,616.04	$12,328,196.52	$6,384,299.75	$4,851,486.71
1911	9,204,616.04	12,333,196.52	6,384,299.75	4,907,486.71
1912	9,204,616.04	12,333,196.52	6,440,454.75	4,907,486.71

Year.	British Columbia.	Manitoba.	Totals.
1910	$702,209.00	$2,878,887.02	$36,424,305.04
1911	798,209.00	2,878,887.02	36,506,605.04
1912	804,209.00	2,878,887.02	36,532,850.04

Following is an analysis of the various forms in which cash aid has been given to railways by the Dominion, by the Provinces and by Municipalities:—

Dominion.

Cash subsidies	$ 80,558,911.30
Loans	25,576,533.33
Cost of lines handed over to C.P.R.	37,785,319.97
Paid to Quebec Government	5,160,053.83
Implement Clause, G.T.P. agreement	4,994,416.66
Total	$154,075,235.09

The Dominion Government is also constructing the Eastern Division of the National Transcontinental Railway, on which an expenditure of $116,533,768.53 had taken place up to March 31st, 1912.

Provinces.

Cash subsidies	$ 32,895,485.16
Loans	2,750,030.00
Subsriptions to shares	300,000.00
Total	$ 35,945,515.16

Municipalities.

Cash subsidies	$ 12,807,324.98
Loans	2,404,498.62
Subscriptions to shares	2,839,500.00
Total	$ 18,051,323.60

Land Grants.

Following have been the land grants to railway:—

	Acres
By the Dominion	31,864,074
By the Province of Quebec	13,625,949
By the Province of British Columbia	8,119,221
By the Province of New Brunswick	1,647,772
By the Province of Nova Scotia	160,000
By the Province of Ontario	635,039
Total	56,052,055

Summarizing the guarantees by the Dominion and Provinces, the result is as follows:—

	1911.	1912.
Dominion	$ 52,439,865	$ 91,983,553
Manitoba	20,899,660	20,899,660
Alberta	25,743,000	45,489,000
Saskatchewan	11,999,000	32,500,000
Ontario	7,860,000	7,860,000
Nova Scotia	5,022,000	5,022,000
British Columbia	23,196,832	38,946,832
New Brunswick	700,000	1,893,000
Quebec	476,000	476,000
Total	$148,336,357	$245,070,045

The above total of guarantees represents an increase for 1912 over 1911 of $96,733,688.

Public Service of Railway.

The public service of railways in 1912 was represented in the carrying of 41,124,181 passengers and 89,444,331 tons of freight.

In passengers carried there was an increase over 1911 of 4,026,463, and in freight hauled of 9,560,049 tons.

Passenger Traffic.

The number of passengers carried in 1912 was 41,124,181—an increase of 4,026,463, or 10.8 per cent. over 1911.

The number of passengers carried one mile was 2,910,-251,636, which was 304,282,712 more than in 1911.

The number of passengers carried one mile per mile of line was 108,888, as compared with 102,597 in 1911. This represented an increase of 6,291 in passenger density.

The number of passengers carried per mile of line was 1,539—an increase of 79 for the year.

The average revenue per passenger per mile was 1.943 cents, which was .001 below the figures for 1911.

The aggregate earnings from passenger service which included express, mails, baggage, etc. was $65,046,186.[illegible] This represented a gain over the preceding year of $[illegible],730,188.21.

The earnings directly from ticket sales to passengers were $56,543,063.60, or $5,976,769.62 more than in 1911.

The average number of passengers per train was 62, as compared with 60 in 1911.

The average passenger journey was 71 miles a gain of one mile over the preceding year.

The average receipts per passenger, using only the revenue from ticket sales as the chief factor, were $1.375 a betterment of .015 as compared with 1911.

The mileage of passenger trains was 40,440,[illegible]3, and of mixed trains 6,473,882 an increase of 3,454,482 miles in the former and of 106,414 in the latter. In preceding calculations these two mileages were combined and used as the total passenger train mileage.

The earnings from passenger train service per passenger train mile—which includes express, mails, baggage, etc.—was $1.387. This was an increase of .030 over 1911.

Freight Traffic.

The volume of freight traffic was 89,444,331 tons, which, as compared with the preceding year, showed an increase of of 9,560,049 tons, or 11.9 per cent. This was the largest increase in the history of Canadian railways.

The number of tons hauled one mile was 19,558,109,52[illegible]—a gain of 3,560,712,232 ton miles as against the figures for 1911.

The number of tons hauled one mile per mile of line was 731,776, which represented a betterment in the density of freight traffic, as compared with 1911, of 99,947.

The average revenue from freight per ton per mile was .757 cent, as compared with .777 in 1911.

Revenue from freight proper amounted to $148,030,898.60, a betterment of $23,287,883.29 over the preceding year.

The aggregate revenue from freight service for the year was $149,961,140.13, which represented an increase of $23,-390,606.61 over 1911.

The gross earnings from freight were equal to $5,610.85 per mile of line—an advance of $626.76 over 1911.

Per ton, gross earnings from freight amounted to $1,655, or .004 better than in 1911.

The average number of loaded cars per freight train was 18.19, or .16 better than for the preceding year.

The average number of empty freight cars per freight train in 1912 was 5.17. The number in 1911 was 5.04.

The average number of tons per loaded freight car was 17.87, showing a gain over 1911 of .96.

The average freight haul was 218 miles, as against 200 miles in 1911—a gain of 18 miles.

The mileage of revenue freight trains was 60,126,023, which included mixed train mileage. This total represented an increase, as compared with 1911, of 6,627,157.

The mileage of loaded freight cars was 1,102,719,543, as against 946,946,917 in 1911.

Following is an analysis of the commodities which are placed in classes that constituted the freight traffic since 1910:—

	1910. Tons.	1911. Tons.	1921. Tons.
Products of agriculture	12,891,351	13,809,536	17,300,945
Products of animals	2,765,006	3,190,702	3,159,280
Products of mines	26,152,022	28,652,236	31,467,709
Products of forest	13,068,940	13,238,347	14,152,721
Manufactures	10,014,279	13,573,987	16,241,081
Merchandise	2,518,190	2,438,089	2,711,963
Miscellaneous	7,073,078	4,981,385	4,410,542
Totals	74,482,866	79,884,282	89,444,331

Of the total freight tonnage of 89,444,331, 63,186,732 tons were returned as "originating on this road." The tonnage so returned in 1911 was 55,152,430.

Earnings and Operating Expenses.

The gross earnings for 1912 were $219,403,752.79 as compared with $188,733,493.81 in 1911. The increment was $30,670,258.98, or equal to 16.2 per cent.

Operating expenses for the year were $150,726,539.87—an increase of $19,691,754.92, or 15.0 per cent.

The ratio of operating expenses to gross earnings was 68.7 per cent.—a decrease of .7 as compared with 1911.

The following table gives the gross earnings and operating expenses, with the ratio borne by the latter to the former, since 1910:—

Year.	Earnings.	Operating expenses.	Percentage of operating expenses to earnings.
1910	173,956,217	120,405,440	69.2
1911	188,733,494	131,033,785	69.4
1912	219,403,753	150,726,540	68.7

Earnings.

The difference between gross earnings and operating expenses was $68,677,212.92, as compared with $57,698,708.86 in 1911. These are popularly regarded as net earnings; but correct accounting methods require that certain deductions, such as interest on funded debt, taxes, rents, etc., shall be made before the real net corporate income is declared Table No. 9, in the body of the subjoined report, deals with the revenues of railway companies in this way.

The balance actually carried forward to profit and loss for the year according to the method followed in the preparation of Table No. 9, was $20,146,869.29, as against $14,150,464.67 in 1911.

The revenue during the year from outside operations amounted to $21,221,774.67, and operating expenses attached thereto, $15,333,617.50. The net revenue from this source in 1912 was $5,888,157.17, or $593,728.35 more than in 1911.

DECREASED PRODUCTION OF IRON ORE

An interesting white paper was recently issued by the British Government, containing statistics of the production and consumption of iron ore and pig-iron and the production of steel in the United Kingdom and the principal foreign countries in recent years, with additionally the imports and exports of certain classes of iron and steel manufactures. It states that the combined output of iron ore in the ten principal countries dealt with exceeded in 1910 139 million tons, and if the output of the minor countries be added it is probable that the world's total production during that year was about 145 million tons. Complete statistics are not yet available for 1911, but the provincial figures show that the world's total output is unlikely to reach more than 120,000,000 tons, the United Kingdom's production figures, however, showing a slight increase.

The total quantity of pig iron produced in the world during 1911 is estimated at about 63,000,000 tons, the principal producing countries being the United States, Germany, and the United Kingdom, which between them account for about seven-ninths of the world's output. Particulars for the first half of 1912 show that the output of pig iron for the five principal producing countries during that period was about 29,400,000 tons, which compares with 27,600,000 tons during the second half-year of 1911. For the second half of 1912 the United States produced about 15,600,000 tons of pig iron, Germany 9,277,000 tons and Belgium about 1,203,000 tons.

EARTH AND GRAVEL ROADS.*

By Robert C. Terrell.†

I feel a delicacy in discussing this very important problem of earth and gravel roads. As this class of roads comprises more than ninety per cent. of the total mileage of roads in the United States, and since there are more than 2,150,000 miles of road, you can readily see how important it is to have the earth and gravel road maintained in good condition for travel.

Earth and gravel roads—as is the case with most of our roads, it matters not of what material they may be constructed—have two natural enemies—water and politics—and the latter point is not to be overlooked. Water, however, is the subject that attracts the greatest attention in the road maintenance; and, since water and politics do not mix very readily, we will discuss the former.

Thorough drainage is the most important problem that confronts the engineer or road builder. Earth roads must be well drained and properly crowned, in order to be serviceable at all times. The maintenance of a road thus constructed is comparatively easy and not very expensive if the work is done at the proper time, but good drainage is very costly, if not altogether impossible, unless the road is properly located.

A road, in order to be properly drained, must have the proper longitudinal grade; a minimum grade of 0.5 per cent., with a maximum grade of 5.0 per cent., which may be increased, depending upon the amount of traffic and the obstacles met in locating. The minimum grade is necessary in order to give the side ditches the proper amount of fall to carry the water quickly and rapidly along and away from the road. The side ditches should be built of a sufficient width to successfully carry all of the water coming into them, having side slopes of 1½ to 1, or 1½ horizontal to 1 foot vertical, which will prevent the earth from the side caving in either from excessive wet weather, or from freezing and thawing. Side ditches should never be made deep and narrow. If extra drainage is necessary, they should be underdrained by use of tile or by excavating a deep ditch, filling with large stones, or making stone boxes and covering these stones with smaller ones and finally covering with sod, the sod side down, or hay, straw, or shavings from a planing mill, to prevent dirt from washing into the inside drain, leaving a shallow ditch on top. Deep, narrow ditches are dangerous to travel and otherwise objectionable, in that they catch trash and cause clogging, thus forming pools along the side of the road, permitting the water to seep into the foundation of the road and soften it. Where roads are located along sidehills a ditch on the upper side sufficient to take all the water coming down the hill is necessary and if it cannot be constructed immediately along the side of the road, there should be an additional ditch constructed above the road and parallel to it, intercepting the water from the hill and carrying it along the same general direction with a sufficiently small grade to prevent washing or gullying of the ditch. Where the grade exceeds 5 per cent., the ditch should be paved with stone and the water should be carried under the road from the upper side at short intervals and disposed of without permitting it to collect in sufficient quantities to damage the side of the road or break across it.

---

* From a paper read before ninth annual convention of American Road Builders' Association, held at Cincinnati,

† Commissioner of Public Roads of Kentucky.

NOTE.—Space allowed only a short abstract of this paper in an earlier number. On account of the number and importance of earth and gravel roads in the Dominion, it has been deemed advisable to publish the paper in full.

Under, or subsoil, drainage is frequently necessary where roads are located on low or marshy soil and should be secured by a line of farm drain tile on either side, or by placing the tile immediately under the road. This farm or porous tile placed 34 to 36 ins. deep, and with a grade of ½ to 1 per cent. longitudinally, will keep the foundation of the road free from water, thus leaving the road hard and compact at all times.

Earth and gravel roads should have more care given to their location than roads surfaced with more permanent material, and probably receive less attention. In locating roads attention should be paid to the character of the surface of the soil over which the road is to pass. Clays form very poor surfaces and even among the clay soils there is as much variation of the fitness of the material for forming road surfaces as there is in variation of soils for farming purposes. These poor soils require more careful study and can withstand the effect due to bad location less than any other materials used for road building purposes. However, in many instances the roads have already been located with little or no prospects of change and to relocate a road means, in many instances, the purchase of expensive rights of way, and the changing of routes often causes trouble, because of the improved property along the old right of way.

For the clay soils, roads should be located where the sun has free access to the surface—preferably having a southern or western exposure and having a small amount of shade from trees and shrubbery. Where sandy or gravelly soil is available, it makes a better location for a road than the softer and less durable soils. As a sandy or gravelly soil sheds water very readily, being more porous, permitting the water to seep down and out; it requires less attention for drainage and shade. Sand makes a better surface for roads when damp.

If the road has been properly located and properly drained, probably the point of most importance is the crown or cross grade. There are several forms of cross section, but the parabola form, in my judgment, is the best, having a centre elevation equal to 1/24 of the width of the road. This form permits the more general use of the entire width of the road, as wagons getting across the middle of the road do not slide immediately into the side ditch. However, the parabola form is more costly, as it requires more care in construction. The uniform slope may be used to an advantage on account of the cheapness of constructing the uniform grade by means of the scraping grader, and probably is just as effective. If the uniform slope is used, ½ to 1 in. to the foot will be sufficient, and if traffic is not permitted to concentrate at the centre of the road and form ruts, the water will be carried quickly and effectively to the side ditches.

Mud holes have no place in roads well crowned, properly located, and properly ditched, and ordinarily they will not occur. However, the surface will become soft by constant pressure of water from underneath and can only be maintained in good condition for travel by putting in the subsoil or porous tile drains. Other frequent causes of mud holes are the unevenness in the texture of the soil and the combining of vegetable matter with the soil while working the roads; this vegetable matter holds water, thus damaging the surface. In no case should stone be piled into a mud hole, as it only forms a rough and unsatisfactory surface and permits the formation of mud holes at either end from the impact of loaded vehicles dropping from the harder surface of stones to the soil surface beyond. The road, however, can be successfully repaired by the removing of the softer soils, or soils containing vegetable matters and replacing with clay, or soil of the same consistency as the remaining portions of the road, and by removing the [illegible] so that the sun may have free access to that portion of the road.

An earth road, like all farm land, should have its principal working in the spring of the year when the soils will work most readily and will have time to become consolidated before the fall rains begin. A scraping grader drawn by a traction engine will do excellent work in giving a road sufficient crown, and the side ditches may also be opened by the use of the scraping grader. The earth removed from side ditches should not be thrown into the centre of the road but should be thrown out to the opposite side or left in such condition that it could be easily removed from the surface of the road entirely and should never be placed where it could be carried back into the ditches by reason of water falling on the surface.

In crowning a road in early spring with a road machine care should be taken that no second or shoulder ditch be left between the centre and the edge of the ditch supposed to carry the drainage, as such a ditch only tends to hold water falling on the surface and soften the subgrade rather than offering an opportunity for the water to be carried away. After the road is properly crowned in the early spring, it will need only slight care during the summer and fall months and in most instances this work can be effectively accomplished by the use of the split log drag. A light drag is preferable, which can be easily drawn by two horses.

It is not necessary for me to go into detail with reference to the construction of one of these excellent pieces of road machinery, as everyone who is interested in road building knows perfectly well the advantages to be gained by the use of a drag.

The amount of road improved by gravel more than equals the amount of road constructed by the use of other materials—probably next to earth roads is the most important—because of the quantity of road surfaced with this material and its low cost and easy method of construction. The same care should be given to the location and drainage as is given to the earth road. In the construction of the gravel road, beginning with the subgrade, it is probably best to open the trench to receive the gravel, giving it the same crown or cross section as the finished roadbed should have, which should be a parabola, with the centre height equal to 1/40 of the width of the road. The subgrade should be properly rolled, beginning at the edges and rolling toward the centre, as you would the finished road, and where soft places or uneven surfaces appear, they should be filled and shaped and the rolling continued until the surface is entirely smooth. The gravel should not be dumped in piles as it forms a wavelike appearance after the road becomes thoroughly consolidated, but should be dumped on boards or shoveled out of the wagon and to the roadbed, spreading evenly and in layers of from 4 to 6 ins.

Gravels containing clay or sand, or even loam, not exceeding 20 per cent. of the entire quantity, make excellent road material and will bind or compact very readily. After the gravel has been properly placed on the subgrade it should be thoroughly sprinkled and rolled, the rolling beginning at the edge of the ditch and rolling the shoulder in the same manner as the gravel, so as to have an even surface for the water to shed from the centre to the side ditch.

In many instances, however, it is not possible to secure a roller for consolidating the gravel. In that case the gravel can be properly shaped and thrown open to travel, care being taken to fill wheel ruts by moving the loose stones in with a rake until the road has been consolidated to an even surface and having proper cross section. If this care is not given to the gravel when first placed and unrolled, ruts will form on either side by the constant rolling of vehicles in the

same tracks and will prevent the water from reaching the side ditches and form channels in which the water will collect and cause much damage.

In western Kentucky our gravel roads cost approximately $1,000 per mile, while in eastern Kentucky, where the country is more hilly and less attention has been paid in the past to the proper maintenance of earth roads, which are being converted into gravel roads, the cost is slightly higher.

In my opinion the maintenance of earth and gravel roads will never be effectively accomplished until we receive government aid for all post-roads and until every road becomes a post-road. I do not mean, however, by "government aid" that the government shall bear the entire or major portion of the expense of constructing or maintaining any road or roads in the Union, but that the government will merely assist in the construction and maintenance of roads to such an extent as will enable the government to direct the local authorities how the work must be done before the federal aid is available, and then that these roads be put under direct government inspection by making each and every rural mail carrier the inspector of his route, reporting deficiencies in the road as they occur to the local authorities and to make reports to the federal government once each month as to the condition of the road.

THE CONSTRUCTION OF REINFORCED CONCRETE SYPHONS OF THE CHENAB IRRIGATION CANAL.

The Chenab Canal, Punjab, India, is the most advanced of what is called the triple canal project now under construction, and with which Mr. Scott, who gave this description at the Institute of Civil Engineers, Ireland, is connected. It obtains its supply from a weir that is thrown across the river just below the point of the offtake of the canal, about 40 miles from the point where the river emerges from the Himalayan Mountains. It has a bed width of 240 feet and a full supply depth of 12 feet, with a discharge of 12,000 cubic feet per second.

The first 26 miles of the main line of the canal passes through a fertile district which has a plentiful rainfall, therefore, no irrigation will take place within its reach, but owing to its proximity to the hills the alignments had to be carried across several drainage lines which, during the rainy season, carry high supplies, therefore, in order to pass the storm water safely under the canal it was necessary to construct several syphons in the upper portions of the head reach.

Of the twelve syphons used eleven were of reinforced concrete, which is an experiment in India, and especially in the Punjab, owing to the extremes of temperature that the concrete will be exposed to, and will be an experience as to how it stands the test. The syphons are cheaper to build and will stand the pressure better than would massive deep foundations of brick masonry, these being more or less submerged, will offer a great protection for the concrete

The dimensions of the largest of these syphons is as follows:—

Estimated discharge	2,550 cusecs
Number of barrels	8
Length of the barrels	342 feet
Diameter of the barrels	6.5 "
Thickness under canal bed	6½ inches
Thickness under canal banks	7½ "
Head of internal hydraulic pressure	15.00 feet
Depth of foundation below spring level	12.00 "
Design of foundation—slab of concrete	2 ft. thick

The Portland cement concrete used in the barrels of the syphons was made up in the following proportions:—

Portland cement	60 lbs.
Sand	100 lbs.
Ballast	160 lbs.
Water	22 lbs.

The Portland cement was obtained from England by indent of the secretary of state of India, and complied with the specifications of the India office. The aggregate consisted of broken quartzite boulders obtained from the bed of the Chenab River and broken in a Baxter stone-breaker to a size that each piece should pass through a ring of half-inch diameter. The sand consisted of the same material crushed to a much finer degree. A block of this concrete, tested after one month, gave a resistence to crushing of 1,380 lbs. per square inch.

The exact proportions of the concrete used in the foundation are as follows:—

Brick ballast	120 cubic feet
Kankar lime	30 "
White lime	10 "
Crushed brick or Surkhi	10 "

It was hand-mixed on brick platforms, carried in baskets to the work, and rammed in 6-inch layers which formed a very hard concrete and was also hydraulic. This syphon will cost in the neighborhood of $50,000 (£10,333).

Nearly every person who has not travelled to India are generally under the erroneous impression that work is done in a leasurely fashion. With only two European engineers to supervise the work of the reinforcement, centrings and laying of the concrete, what would be a simple operation in this country assumed large proportions in India, as the work was new to the men and the staff and coolies had to be trained up to the work, which was done under awnings to protect the concrete from the heat of the sun. But, despite all this, and with the temperature nearly always in the neighborhood of 90 degrees Fahr., the work was completed well within the anticipated time.

UNION FREIGHT STATIONS.

Union freight stations will in time be established in all large commercial centres, says L. C. Fritch, chief engineer of the Chicago Great Western Railroad.

A plan for consolidating the passenger and freight terminals in Chicago has recently been proposed. The plan is commendable, although to bring it about certain railroads would have to give up valuable vantage points in the interests of economy and improved service for all. The union terminal should, Mr. Fritch believes, be operated by a terminal company, equal service being rendered to all lines. This undertaking, tremendous at first thought, is nevertheless feasible and is simplified by the fact that Chicago is the terminus of all the lines entering the city, so that only small portions of the ends of main lines would be out of the hands of the individual railroad companies.

A step toward such a plan would be the aquisition of all belt lines now existing in the Chicago district. They should be owned jointly by all the railroads entering the city, and should afford all such railroads equal access to all facilities and industries located on them. There are four or five principal belt lines in the district, and in some cases lines badly congested are paralleled by lines little used. Common ownership would make it possible to balance the traffic on the different lines, would eliminate the necessity for increased facilities on the lines now congested, and would enable each road entering the city to get its belt line service at actual cost.

CONTENTS OF THIS ISSUE.

A COURSE IN HIGHWAY ENGINEERING.

In an address given before the recent Ontario Good Roads Association meeting, Mr A. T. Laing, the secretary of the Faculty of Engineering, University of Toronto, outlined the plans of that institution to meet the present-day requirements of trained highway engineers. Dean Galbraith, as the head of the Faculty of Engineering, is again to be congratulated on his continued putting into force of those lectures and courses which improve the value and opportunities of his graduating students. In their final year they are to be given besides lectures on roads, pavements, maintenance, etc., a laboratory course in the examination of road metals and bituminous materials.

Modern highway engineering cannot be properly carried on without the employment of technically trained men. With the present-day movement towards good roads throughout the country, every school of engineering should make provision for special lectures in that branch of work. Some of the state road associations across the border make special provision for keeping young men working with them on practical work in the summer and attending schools and lectures on highway engineering in the winter. No doubt some such arrangement will be arrived at in this country as the demand for such men increases.

Students spending their summers on practical road work of different types, obtaining in the winter supplementary technical information on the subject, ought to be in a position to be of considerable service when they graduate. The schools of engineering and road associations in all parts of Canada should work together to this end. The full text of Mr. Laing's address on this subject is given on another page.

ELECTRIFICATION OF RAILWAYS.

The Chicago, Milwaukee and Puget Sound Railway is preparing to operate electrically through part of Montana and Idaho, and has signed a contract for the electric energy needed. In so far as many Canadians expect to see some of our steam railways finally forced through economy of operation to electrify in many localities, it is of interest to note the terms of the contract made for power by the railway in question.

The railway is not to be liable for interruption to its consumption of energy due to causes beyond their control, such as strikes, fires, etc. Neither is the power company liable for interruption to supply due to the same causes. Two years' notice to commence delivery of energy must be given the power company, and the railway must electrify its line before 1918. The railway agrees to buy energy at the rate of 10,000 kilowatt for a full period of ninety-nine years. It has options to buy more power from the power company up to a maximum of 25,000 kilowatt. The permissible call for additional energy from the power company is scaled both as regards amounts and necessary time notice beforehand. These additional amounts once called for will be delivered for the entire remaining time of the contract. The power company in making delivery of energy, is to provide

energy at either 50,000 volts or 100,000 volts, three-phase, sixty cycle, and is not to be called on to deliver at more than five stations; the railway company to be responsible for distribution. The railway is also forbidden to sell to others any of the energy purchased.

In an endeavor to avoid any misunderstandings, provision has been made for a board of arbitrators to settle disputes of any nature between the companies interested. This board is to consist of three parties, one representative from each company and the third party selected by the first two.

Such a board is to be commended, and ought to facilitate the efficient operation of such big contracts where it is almost impossible to cover all the details of construction and operation beforehand. The more general adoption of such a board of arbitrators in connection with contracts of this character should rather be encouraged.

The power company pays the federal government a tax of five mills per 1,000 kilowatt hours for energy crossing domains. The rate paid the power company by the railway for energy is 5.36 mills per kilowatt hour. This is subject to a minimum bill of 60 per cent. of all the energy contracted for by the railway. It will be seen that this provision of a minimum charge makes it incumbent upon the railway to operate so efficiently that 60 per cent. of the energy supplied is under use. Otherwise, they will not benefit by the low rate.

UTILIZATION OF TIDAL ACTION.

Readers will remember a few years ago that the newspapers had considerable in their columns regarding a scheme for utilizing tidal action for developing electricity. The Bay of Fundy has a tidal movement of 50 or 70 feet, and was spoken of as the locality where electric development by this means would be immediately started. A site was spoken of, but it is our impression that no construction work was ever started. Apropos of the above comes word of plans for development in Europe of 5,000 horse-power by this means at Husum on the North Sea.

A reservoir of 4,000 acres is to be constructed by means of two embankments running from an island to the mainland. The reservoir is to be further subdivided into an upper and lower tank by another embankment. The assumptions for operation are as follows: When the water in the sea is higher than in the lower reservoir or tank, it will flow in through turbines, the flow starting sometime after high tide and stopping after the beginning of low tide. If the water in the sea be lower than in this tank, then through sluices it is to flow into the sea. In the upper reservoir, when the sea is higher than the tank, it will be filled through sluices, and when lower the water will flow off through turbines. A uniform tidal amplitude of three meters is counted upon and a difference of level of one and a half meters between the sea and the tank actually in operation. The cost of producing electricity by this means is estimated at 20 to 25 mills per kilowatt hour. No necessary expense for accumulators is expected, and the cost of construction is placed at about $1,000,000.

The scheme has been very severely criticized in a German technical paper by Mr. L. Benjamin. While it is not our purpose to pay any attention to his criticisms of the estimated expense of the project, we think criticism of the practical operation of such a plant worth considering and interesting. If it is a feasible and practical plant at all, with a tidal amplitude of only three meters, it ought to mean wonderful possibilities for electrical development in Canada in the Bay of Fundy. In the criticism of the practical operation of such a scheme by the German paper before mentioned, the objections are principally on the following points:—

After making allowance for back pressure and the head necessary to bring the water from the remoter parts of the reservoir to the turbines, the maximum head available would only amount to one meter, and falls to zero in a working period. In the most favorable case the dynamos would only work for a period of about four hours, followed by a standstill of two hours. The energy would have to be stored for distribution to consumers, and expensive accumulators would become necessary. Turbines suitable for one meter head are not suitable for less than one-half meter, and consequently more turbines become necessary.

Summing up the criticism, it amounts to the fact that the final cost of electric energy delivered to the consumer by this plan would be prohibitive and far beyond a properly designed steam plant.

The affair, as far as a proposed plant at Husum is concerned, savors of wild-catting and stock promotion. The market for the distribution of energy is at considerable distance from the proposed site, and in every way it would appear to be a very expensive and impractical plant.

In Canada it is probable that the inland water powers are sufficient, and can be more economically developed for the use of the people of New Brunswick and Nova Scotia than any possible present harnessing of the high tides on the shores of the Bay of Fundy. It is interesting, however, in looking forward, to see a tremendous field for electric development as above in Eastern Canada. The Bay of Fundy is the locality of the greatest tidal amplitude of movement in the world. It will be strange, indeed, if the first works to put the scheme to practical test are not located there. Any urgent demand or necessity for power in that region will probably lead to an attempt to develop electric energy by the above means.

EDITORIAL COMMENT.

Oil production in Canada, as shown in the statistics published on another page, is steadily decreasing. This is probably the only product of Canada's wealth or natural resources, the production of which has steadily declined in the last five years. We are of the opinion that this movement is only temporary. There are yet tremendous and promising tracts of land to be properly prospected for oil. It is to be hoped the engineer and geologist will soon locate it in abundance. It would be unfortunate, indeed, if, as a country, we were lacking in such a product, so largely used in the arts and manufactures.

STORM WATER DISCHARGE.

R. O. Wynne-Roberts * and T. Brockmann.†

(Continued from page 375).

Before proceeding to explain the method of constructing flow areas and curves, it will be necessary to submit the following formulæ:—

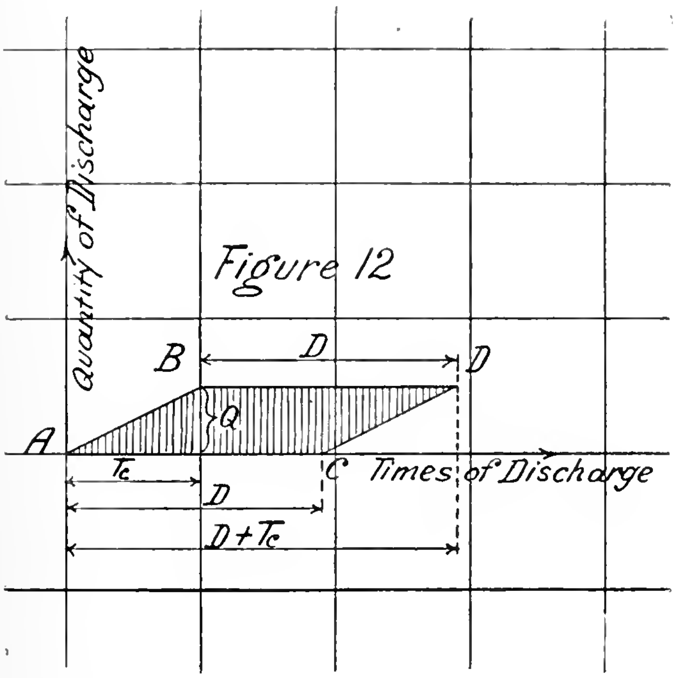
Let Q = Volume of storm water discharged in cubic feet per second, when the whole of the drainage area is contributory.

Qt = Volume of storm water discharging at any time during or after a storm, in cubic feet per second.

P = Coefficient of impermeability, taken from diagram or table.

R = Quantity of rain, reduced to cubic feet per second per acre.

I = Coefficient of rainfall intensity, see table or diagram.



A = Drainage area, in acres.

Tc = Time required for storm water to concentrate at the lower end on the sewer of "L" length, in minutes.

L = Length of sewer, in feet.

V = Mean velocity of flow in sewer, in feet per second.

D = Duration of storm, in minutes.

T = Any time, in minutes.

Then (1) $Tc = \frac{L}{V}$

and (2) $Q = P \times I \times R \times A$.

In the preliminary design of a sewerage system the length of any particular section is known, and the velocity of flow may be assumed at, say, three feet per second, when running half-full or full, so that the time Tc required for the storm water under such condition to flow from point to point can be easily ascertained by formula (1).

The duration of a storm is "D," and the ordinates representing the volume of storm water "Qt" for any time "T" will be as follows:—

If "T" is greater than zero and less than "Tc," then

$$Qt = \frac{T}{Tc} \times Q.$$

If "T" is greater than Tc and less than D, then Qt = Q.

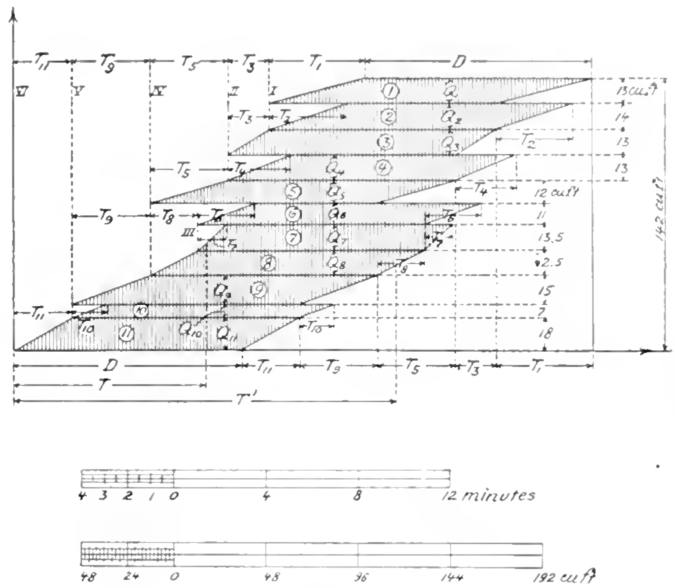


Fig. 14.

If T is greater than D and less than D + Tc, then

$$Qt = \frac{(Tc\ D) - T}{Tc} \times Q.$$

If (D + Tc) is less than T, then Q = O.

(See Figure 12.)

The left-hand slope A-B (of Figure 12) of the flow-area is parallel to the right-hand slope C-D.

The volume of storm water run-off is represented by the flow area, having the shape of the rhomboid A-B-D-C, and the period of concentration, as well as the quantity discharged at any time at the lower end of any sewer having "L" length, and during any storm of "D" duration is clearly indicated in the diagram (Figure 12). It may be explained that in this case the direction of the flow is from the right

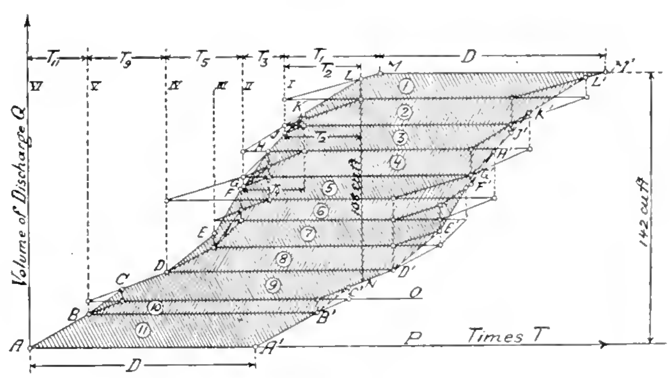

Fig. 15.

to the left, and the outlet is situated at the toe-point A.

Recapitulation.—It is to be hoped that what has already been stated regarding the problem of calculating the quantity of storm water, to be dealt with in any district, has been expressed in explicit terms, and that it will be recognized that, having regard to the variable factors which have to be considered, the best way of arriving at a satisfactory solution will be by drawing flow-areas.

* M. Inst. C.E., F. R. San. Inst., Consulting Engineer, Regina.

† Dipl. Ing. (Berlin), Civil Engineer, Regina.

The engineer will, therefore, have first to

1. Assume the intensity of the rainfall.
2. To ascertain if retardation takes place.
3. If retardation does not take place, then use formula.
4. If retardation does take place, then to draw flow-areas.

Example.—A complete example will now be worked out to illustrate the method which the writers submit is the more rational one to follow.

Plan shown in Figure 13 is presented as a typical layout of a sewerage system for storm water. There are six sections to which eleven areas are to be drained.

Assumptions—

Duration of storm = 10 minutes, or 600 seconds.

Rainfall = 2 cubic feet per second per acre.

The volumes of discharge for the other ten areas can be arrived at by analogous calculations and the following results will be obtained:—

Section	1	13 cubic feet per second.
"	2	14 " " "
"	3	13 " " "
"	4	13 " " "
"	5	12 " " "
"	6	11 " " "
"	7	13.5 " " "
"	8	12.5 " " "
"	9	15 " " "
"	10	7 " " "
"	11	18 " " "
Total		142 cubic feet per second.

So that the total discharge at manhole VI. amounts to 142 cubic feet per second.

Figure 14 shows the floor area for each section and drainage area illustrated in Figure 13.

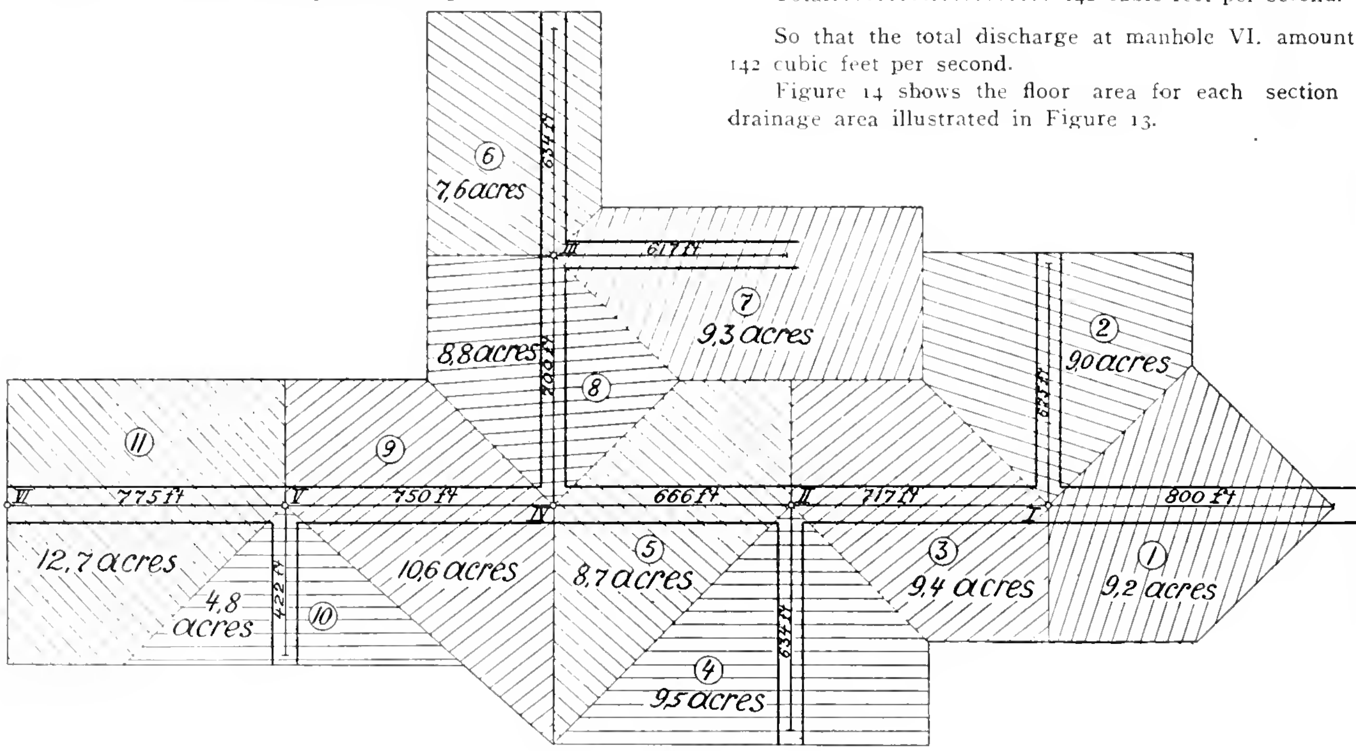

Fig. 13.

Scales of the flow-areas are—

Time one inch = four minutes.

Volume of discharge, $\frac{1}{48}$ inch = 1 cubic foot.

Commencing with Section 1—

L = 800 feet.

V = 3.2 feet per second.

Time of concentration $= \frac{L}{V} = \frac{800}{3.2} = 250$ seconds, or 4 mins. 10 secs.

Coefficient of impermeability for, say, 70 persons per acre, as per diagram = 0.77.

Coefficient of intensity for a section 800 feet long, as per table, equals $1 - 0.0028\sqrt{800} = 0.92$.

The drainage area for Section 1 is 9.2 acres.

Accordingly the volume of discharge will be:—

Q = Area × rainfall × coeff. of impermeability × coeff. of intensity.

$Q = A \times R \times P \times I = 9.2 \times 2 \times 0.77 \times 0.92.$

Q = 13 cubic feet per second.

Having ascertained the time of concentration and the volume of discharge as above, the flow-area is plotted in the top right-hand portion of the diagram (Figure 14).

Those who wish to draw similar charts may be guided by the following simple rules:—

1. Start by drawing the flow-area of the section of sewer lying near the remote limits of a district, that is, the farthest from the point of outlet, and then proceed, section by section, downwards, in the direction of the flow.

2. Flow-areas of sewers which meet at a manhole have the same abscissæ; i.e., the toe-points of their ascending slopes are located perpendicularly above each other.

3. The flow-area of a sewer section located between two manholes is to be drawn beneath those of the upper sections, the toe-point being moved leftwards a distance corresponding to the time of concentration for that particular sewer.

4. Secondary collecting sewers joining the main sewers will have to be dealt with in a similar manner.

The chart illustrated in Figure 14 has been constructed in accordance with the foregoing rules.

The volume of discharge passing through manhole VI. at the time "T" is represented by an ordinate erected at "T," and cutting the flow-areas 11-5. The parts of the erected ordinate which signify discharge are those which lie within the shaded areas. The flow-areas 4-1 are not passed through by the ordinate, which shows that they are not yet contributing, whereas, at the time "T¹" the sections repre-

sented by the flow-areas 8-1 are discharging into manhole VI., while the water from sections represented by flow-areas 11-9 has already run off.

Figure 15 has been prepared by depressing the projecting points on the left and elevating those on the right to the area next to them, and so a flow-curve is obtained which is characteristic for the volume of storm water discharge at any time from the whole drainage area under discussion.

It will suffice to construct only the ascending curves A-B-C, etc., because the descending curves M'-L'-K', etc., are parallel to them.

The largest ordinate of the total flow-area will give the maximum rate of flow on which the calculations of the sewer dimensions are to be based.

In the present example the ordinate L-N shows this maximum rate of flow to amount to 106 cubic feet per second, and this is the volume of storm water that must be provided for in Sections 9, 10 and 11.

The difference between M-P and L-N indicates how much the storm water discharge is modified by retardation. In this case the difference equals 142-106, or 36 cubic feet per second. In a like manner the difference between M-O and L-N represents the modification of the aggregate flow due to retardation in Sections 1 to 9 inclusive.

In conclusion, the writers have to urge upon city engineers and others the desirability of installing automatic recording rain gauges so as to obtain reliable information concerning the quantity of rain falling in short periods and in different districts, for without this data it is possible that the assumptions which will be made when designing storm water sewers may be erroneous and lead to inadequate or excessive provision for storm water. In each city the rainfall should be automatically recorded for those having a duration of 2 to 120 minutes, and such data plotted as shown in Figure 1, illustrating the intensity of rainfall. The rain gauges required for this purpose are to be had at a moderate price, whilst the information thus secured will be of great value.

NOTE:—The issue of The Canadian Engineer, Feb. 20th 1913, page 344, containing a preceding article by R. O. Wynne-Roberts and T. Brockmann on Storm Water Discharge, did not, unfortunately in printing, bring out many of the symbols r belonging to q. The part of the page needing correction is here reprinted together with more distinct $\sqrt{}$ signs and the omission of a dash over an x.

The corrected page should read:—

Line 22 — $\frac{q}{2}$ correct to "$\frac{q_r}{2}$".

Top of right hand column same page should read:

Let "A" be the zero point, then the parameter "p" is found from $10{,}000 \times p = \left(\frac{q_r}{2}\right)^2$ or "p" equals $\frac{q_r^2}{40{,}000}$; the equation of the parabola will be "y^2" $= \frac{q_r^2 \times x}{40{,}000}$.

The circumference described by the centre of gravity in revolving is $2 \times 0.6\, x \times x$, therefore the content of the solid of revolution corresponding to the shaded area (cylinder minus parabola) is $x^2 \pi\, q_r - \frac{2}{3}\, x\, y\, 1.2\, x\, \pi = x^2 \pi\, (q_r - 0{,}8\, y)$ and "I" $= \frac{x^2 \pi\, (q_r - 0{,}8\, y)}{x^2 \pi\, q_r} = 1 - 0{,}8 \frac{y}{q_r}$.

As $\frac{y}{q_r} = \sqrt{\frac{x}{40{,}000}}$, "I" $= 1 - \frac{0{,}8\sqrt{x}}{\sqrt{40{,}000}}$.

FAULTY CEMENT WORK.*

So simple does it seem to mix cement, sand, stone, and water, and embed therein steel rods, that the ordinary mind untrained in the refinements of technical calculation is apt to overlook the fact that a complicated theory underlies the construction. There are, consequently, builders who, while they would not dare to undertake a steel structure, yet consider themselves sufficiently "practical" to take a hand at reinforced concrete. Incompetence is thus too often set on high, and no more vengeful Juggernaut was ever enthroned to exact tribute of suffering and death.

To plan and to superintend reinforced concrete construction—we cannot repeat it too often—calls for more than the experience and common-sense of the so-called "practical" man; it is eminently work for the trained engineer.

No more emphatic demonstration of this was ever given than the example of failure presented in the remains of a motion picture theatre on Eastern Avenue, Cincinnati, Ohio, which was to have opened on New Year's day with a grand free-for-all show for as many women and children of the neighborhood as could crowd it. For weeks, every child in the neighborhood had been watching the completion of the new picture theatre; and many of them were all joy, for their mothers had promised to take them to that free show on New Year's day. By an act of the merciful hand of Providence, however, none of them attended. for, on December 10, the nearly completed theatre, without preliminary warning long enough to give the unsuspecting workmen a chance to escape, collapsed to the ground, carrying with it the ten workers who happened to be in the structure, instead of that happy throng of women and children. Had the structure stood until that opening day, it is conceded by all that it would have been the death trap for two hundred or more mothers and their children. As it is now, the story is three dead, six seriously injured, and one bruised.

The building was a reinforced concrete substructure of columns, beams, and slabs, with brick side and end walls forming the theatre proper. The concrete work was originally designed by an engineer employed by the architect; but it appears that the owner, on account of the high bids received, engaged a "practical" builder, who prepared his own plans, modifying the work of both the architect and the engineer, and agreeing to do the work for much less than the amount of the lowest bid. Neither architect nor engineer had anything to do with the supervision of the erection. Even the plans on which the building permit was issued were not followed out exactly, one column being omitted, thus increasing span between columns; and though the building commissioner required that the details of the girder to support the floor across this span be submitted, the builder failed to submit them.

The collapse occurred while the forms were being removed. The concrete had been in place only 18 days, the weather being generally cold and for a considerable part of the time below freezing. The folly of the whole thing, however, is strikingly shown in the way the steel was placed, no intelligent care whatsoever having been exercised. The rods in the girders were simply bunched together along the bottom, without being spaced so as to enable the steel to have any effective grip.

---

*Cement World.

Mr. J. G. Sullivan, chief engineer of Western lines of the Canadian Pacific Railroad, has stated that tenders are being called, to close April 15, for a great tunnel 28,000 feet long to cut through the Roger's Pass Hill.

REPORT OF THE TWENTY-SEVENTH ANNUAL MEETING OF THE CANADIAN SOCIETY OF CIVIL ENGINEERS

(Continued from last week).

Thursday, January 30th, 1913

Morning Session

THE PRESIDENT said they would continue the discussion re British Columbia Branches.

MR. ROBINSON said it appeared to him that this question was too large for a snap judgment. The matter needed thorough consideration over an extended time, so that whatever action they might see fit to take in this matter should be well weighed and their judgment mature.

He moved that the Council be instructed to take this matter under advisement and thoroughly thresh it out, with a view to proposing any amendment to the by-laws which may be necessary to accomplishing this which we are asking for.

He hoped that the matter would not take the form of action which would in any way weaken either the interests of the parent society or of the branches. They hoped that whatever action was taken would tend to increase the strength of both, thereby making a stronger and more vigorous society in every respect. In the discussion after the meeting yesterday afternoon informally, it was brought to his attention that some of the members considered it unnecessary to seek incorporation from the Provincial Government of British Columbia, and that the only thing necessary in the circumstances would be to register this society, which had a charter from the Federal Government, as an extra provincial organization doing business in British Columbia. His opinion at the present time was that that would accomplish the objects which they had asked for fully as well as to secure an independent charter. If the council saw fit to take such action, he would like to have this meeting give the council such authority as might be necessary to secure this act. Possibly that could be done before the end of the year. He would like to have that discussed. He would make it as a motion.

THE PRESIDENT understood the motion to be, that the question of establishing a British Columbia branch be referred to the incoming Council.

MR. ROBINSON assented, adding "with power to act."

MR. LeGRAND seconded that motion.

MR. MOUNTAIN said the whole matter of the British Columbia section had been laid before them by Mr. Robinson in a very fair-minded spirit. The tone of his speech was conciliatory and temperate and admirably adapted to the subject. He made this motion that it be turned over to the Council to suggest amendments in the by-laws, if necessary, and then he said that he hoped action would be taken before the end of the year. Of course, that was a long period, but at the same time could amendments be put through between now and the next meeting?

THE PRESIDENT stated the only thing that could be done would be to have them ready for the next meeting.

The motion was then put and carried.

MR. ROBINSON had just one more matter to bring before the meeting.

There was a tendency on the part of politicians in all countries to use the prerogative of appointments as spoils of political battle. He thought that the citizenship of the country at large would approve if the society discouraged that attitude on the part of politicians. If there was anything within the power of the Council that they could do to discourage that attitude it would be probably conferring a boon upon all the citizens of the country, and especially upon engineers who are in the employ of the government.

MR. ROBINSON said in the absence of another to propose his motion he would like to place it in the form of a resolution:—

Resolved, that we, the Canadian Society of Civil Engineers, do heartily endorse the attitude taken by many of the officials of our government towards the matter of separating party politics from the engineering interests of the government, and anything we can do to further such attitude we will enter into with all zest.

MR. JAMIESON was pleased to second that.

MR. DUGGAN was in sympathy with that motion, but he did not think the form in which it was couched was felicitous. The same object was being achieved in another way, by asking the government to create a strong permanent corps. He thought they could eliminate all questions of politics. That had been carefully omitted all through in connection with that matter.

THE PRESIDENT asked if it would not be well to write out that resolution.

MR. ROBINSON thought the sentiment expressed in the resolution met entirely the views of the members, and they could safely trust to the Council or secretary to put it in diplomatic form.

THE PRESIDENT said the resolution would be worded by the secretary.

The motion then carried unanimously.

Proposed Committee on Reinforced Concrete Construction

THE PRESIDENT said there was some correspondence at hand from Mr. Almonte asking that the society form a committee on reinforced concrete construction.

MR. ALMONTE begged to propose that the society appoint a committee to work out specifications for reinforced concrete structures. Canada was one of the countries where reinforced concrete is very largely used. Most European countries and the United States years ago deemed it advisable to get out such specifications containing general rules to ensure safe construction. There was only one public body here in Canada which had issued such a specification, and that was the city of Toronto.

He thought it would be a great benefit to the Dominion if this society took this matter up, and if it were to do so the probability is that its recommendations would be adopted by all public bodies. It would not only ensure safe construction, but avoid the endless multiplicity of specifications

which now prevail in the United States. And it would be a credit to the society to take this matter up now.

MR. MOUNTAIN proposed that it be referred to the incoming Council.

Carried.

Transportation Route Committee

MR. KENNEDY here said that they would all remember about the formation of the General Committee on Transportation. It was sub-divided into committees, of which several have been mentioned, and amongst others was one on transportation routes. It was erected some two years ago in Winnipeg into an independent committee.

Now, the Transportation Committee as a whole has really done almost nothing. The first chairman was Mr. McNab, who resigned after a time, then Mr. Mountain followed, and the president after him, and then he (Mr. Kennedy) was appointed some time ago. The subject seemed to him to be tremendously large when he sat down to consider it and try to do something about it. The president had written an important paper on four transportation routes between Fort William and Montreal, and Mr. Jamieson had also done a good deal personally in the same way. Mr. Coutlee had also done something, but as a committee they had not been able to get together and do much.

Looking over the subject as it stands, transportation routes take in everything from Hudson Straits down to Lake Erie and from Cape Breton to Vancouver Island, and that would be connected again on the Pacific side with the Panama Canal and Liverpool, and the same on this side. Then there is railway transportation as well as water transportation. It comes to be a tremendous subject unless it is more particularly defined than it is now.

Although they got permission from the Council to engage an expert, yet he confessed he hardly saw how the committee, as a volunteer committee, unless there was somebody engaged who would be at it all the time, could make a report which would be worthy of the society and have any weight.

He had grave doubts as to the usefulness of continuing the committee, and if it is continued possibly the constitution of it could be looked over to make it more concentrated. He was not prepared to make a definite recommendation in the matter, but he put it before the meeting so it might be considered.

MR. JAMIESON said, as a member of that Committee on Transportation, he confessed to a great deal of disappointment that they did not succeed in accomplishing what they had set out to do. It was a very difficult matter to deal with, and they have had a great many changes of chairmen, and some members, no doubt, had not been able to give the time and attention to it that was expected. He knew that their president, who was chairman of that committee, devoted a lot of time to it and got out quite an extensive report on the railway end, and some on vessels as well. For himself, he certainly did devote a very large amount of time and considerable expense to it. Month after month he had worked on it from time to time, and he had got his data in such complete shape as would make it very valuable on this question. And yet, to-day they had practically, as a committee, produced nothing.

THE PRESIDENT, after some discussion, suggested that Mr. Jamieson, after going to all the trouble he had, should write a paper for the society.

MR. MOUNTAIN moved that the Committee on Transportation Routes be disbanded.

He thought if the members who had worked on it [illegible] present their information in the shape of a paper it would be a valuable addition to the transactions. If they so desired, they could say the paper was presented more for discussion than as their firm conviction.

The motion to discontinue the committee then carried.

Re Committee on Portland Cement and Concrete

MR. JAMIESON wished to say a word or two in connection with the Committee on Portland Cement and Concrete. Unfortunately, they were not able to report for this meeting. It was something like the question of transportation routes, it covered a great deal of ground and required a great deal of data to be accumulated, and while they had got that very fully, yet, it was a matter of a good deal of work, and will take a good deal of time formulating a report. He had been considering the question of dealing with it in a paper or a lecture to bring out the information they had collected on the question of the effect of sea-water on cement and concrete. That will bring out the matter much more fully than can be done in a report, and then they could make a short report at a later date based on that.

Report of the Gzowski Medal Committee

THE PRESIDENT said he had a report by wire from the different members of the Gzowski Committee. The chairman of that branch was away ill, so that they had to get the views of the different members by wire. They were unanimous in recommending that Mr. R. F. Uniacke be given the Gzowski medal for his paper on "The Little Salmon River Viaduct."

This was confirmed by the meeting unanimously.

Report of Scrutineers

The next business was the report of the scrutineers.

BALLOT FOR SPECIFICATIONS.

The secretary read the report for the ballot for specifitions.

THE PRESIDENT presumed this meeting should instruct the Council that these specifications be printed and distributed.

Carried.

BALLOT FOR AMENDMENT TO BY-LAWS.

The secretary read the report as follows:—

By-law 23.—Ayes, 306. Nays, 126. By-law carried.
By-law 24.—Ayes, 339. Nays, 76. By-law carried.
By-law 51.—Ayes, 306. Nays, 47. By-law carried.
By-law 55.—Ayes, 355. Nays, 30. By-law carried.
By-law 20.—Ayes, 325. Nays, 74. By-law carried.

BALLOT FOR ELECTION OF OFFICERS AND MEMBERS OF COUNCIL.

The secretary read the report as follows:—

President—Phelps Johnston.

Vice-President—F. C. Gamble.

Councillors—District No. 1.—J. M. Fairbairn, W. J. Francis, R. J. Durly.

District No. 2.—F. A. Bowman.
District No. 3.—W. D. Baillairge.
District No. 4.—S. J. Chapleau.
District No. 5.—H. E. T. Haultain.
District No. 6.—W. A. Duff.
District No. 7.—T. H. White.

THE PRESIDENT then declared the foregoing gentlemen elected.

NEW BUSINESS

MR. HARKOM moved that the Council be requested to consider the advisability of forming a Montreal branch to operate on the same lines as other branches already formed.

MR. CROMPTON said, in seconding that motion as an out-of-town member, that it seemed to him there was a feeling, particularly among the out-of-town members, that they were not getting value.

THE PRESIDENT said he understood the motion was that the Council shall give its serious consideration to the question of starting here a Montreal branch.

MR. KENNEDY, in discussing the motion, said he noticed this resolution was put forward by gentlemen who were not members resident in Montreal, and not members of any other branch, and have had no real experience in this matter. He thought it would tend to worse confusion if they were to try to make a Montreal branch here. For the society to legislate at this point that Montreal should erect itself into a branch would be very much the same as if the Quebec Legislature ordered the city of Montreal to widen a street which the city knows much better about itself.

This matter of papers which seemed to be behind the motion, he thought, possibly they had a wrong idea about. They must remember that at the present time the whole country is flooded with technical journals. They had English, French, and above all, American journals, and the members had their own "Canadian Engineer," which was becoming a good engineering paper. (Hear, hear). So, it was practically impossible for a busy engineer to do much more than keep up with the procession, to keep on reading what was coming up. All the best papers of the engineering societies were published in the engineering papers.

They were trying to put upon the Council and the committees what was really the duty of individual members.

He did not think the annual meeting was quite the right place in which to order the members in Montreal to form themselves into a separate branch independently of the Council, because the thing was not workable and would really complicate matters and induce confusion.

Let those members who wanted to write papers write them freely, and not scold too much those who did not write when they themselves are not setting an example.

MR. ROBINSON said in order to relieve this body from the embarrassment which may follow, an accusation of usurping the power of Montreal members to do something which they wish not to do, he would make it a motion that this whole matter be left in the hands of the Council to deal with as they see fit. That the motion be not put as a vote, but simply recognized by the Council as a suggestion.

MR. JAMIESON said it appeared to him that the mover and seconder would probably withdraw their motion as a motion before the society on the promise that the president had already made that the Council would take it up and consider it.

MR. HARKOM said he only asked the Council to consider the advisability of it. He certainly felt that in their hands the matter would receive fair and due attention.

Scale of Engineering Charges

MR. J. S. ARMSTRONG moved the following resolution:—

That the Council be requested to appoint a committee to consider and, if possible, draw up a schedule or scheme of charges for engineering services.

MR. LEOFRED seconded that motion. All the professions, notaries, land surveyors, doctors, have got what they call a minimum charge. This would only refer to the minimum charge, he understood.

THE SECRETARY said that he thought it was in the knowledge of members of the Council that this matter engaged the attention of the Council something like a year ago, and that even the proposer of the tariff scheme himself failed to put up anything that he could satisfy himself with. They had spent some time over it and came to the conclusion that it would utterly fail.

The motion was put to the meeting after some discussion and defeated.

Re Specifications for Steel Water Pipes

THE SECRETARY said a member of the society, Mr. Pitcher, telephoned him just then to say he intended to be here in order to ask that the matter of appointing a committee to consider specifications for steel water pipes be referred to the Council. He now finds he cannot get here. The secretary supposed this matter might be included in the others remitted to the Council.

MR. VAUGHAN moved that it be referred to the Council.

Election of Nominating Committee, Officers and Members of the Council

The next business was the election of a Nominating Committee.

THE SECRETARY said the following were the nominations by the Council for the formation of a Nominating Committee, and the by-laws required that this Nominating Committee shall be elected by the Annual Committee. Suggestions have been received from the branches, who have taken some means to ascertain the views of their members. The suggestion in regard to the local member is that of the local members of the Council. The suggestion for District No. 2 is from the local councillors in the Maritime Provinces.

The following name was suggested as a member of the Nominating Committee for District No. 1, H. M. Jacques.

Adopted unanimously.

THE SECRETARY said District No. 2, which was the Maritime Provinces and the United States, put forth two names, F. W. W. Doan and G. Stead.

On being put to the meeting, Mr. Doan was declared elected.

District No. 3, Province of Quebec, F. X. A. Leofred and R. O. Sweezie.—Mr. Leofred was elected.

District No. 4, Alexander McPhail and James White.—Mr. White was elected.

District No. 5, J. G. Sing.—Elected.

District No. 6, W. L. McKenzie.—Elected.

District No. 7, J. H. Grey and L. G. Robinson.—Mr. Robinson was elected.

Votes of Thanks

MR. MOUNTAIN moved a vote of thanks of this meeting to the railways of the Eastern Passenger Association, to the Montreal Tramways Company, to the Canadian Foundry Company, Limited, and to the Canadian Pacific Railway for courtesies extended to the members in session at this annual meeting.

This was seconded by Mr. Monsarrat and carried unanimously.

MR. McNAB proposed that the Council be requested to convey to the Dominion Conservation Commission the thanks of the society for the valuable copies of the reports of the

commission which were furnished gratis to the members of this society.

This was seconded by Mr. Duff and carried unanimously.

THE PRESIDENT then said if there was no other business to be brought before the meeting he would declare it closed.

The meeting then adjourned.

PETROLEUM.

The annual output of crude petroleum from Canadian oil wells, for 1912, still continues to decline, the production having steadily fallen off during the past five years. Twelve years ago Canada produced about 50 per cent. of the domestic consumption of petroleum and its products, while at the present time not over 5 per cent. of our consumption is derived from Canadian oil wells. The output in 1912 was 243,336 barrels or 8,516,762 gallons, valued at $345,050, as compared with 291,092 barrels or 10,188,219 gallons, valued at $357,073 in 1911. The average price per barrel at Petrolea in 1912 was $141 or considerably higher than the average price in 1911, which was $122⅔.

The price of crude oil increased steadily through the year, rising from a minimum of $1.24 in January to a maximum of $1.65 in the latter part of December.

These statistics of production have been furnished by the Department of Trade and Commerce and represent the quantities of oil on which bounty was paid, the total bounty payments being $127,751.39 in 1912 and $152,823.20 in 1911.

The production in Ontario by districts as furnished by the supervisor of petroleum bounties, was in 1912 as follows in barrels: Lambton, 150,272; Tilbury and Romney, 44,727; Bothwell, 34,486; Dutton, 4,335; and Onondago, 7,115; or a total of 240,935 barrels. This agrees very closely indeed with the production in Ontario on which bounty was paid, viz., 240,657 barrels. In 1911 the production by districts was: Lambton, 184,450; Tilbury and Romney, 48,708; Bothwell, 35,244; Dutton, 6,732; and Onondago, 13,501.

The production in New Brunswick in 1912 was 2,679 barrels, as against 2,461 barrels in 1911 and 1,485 barrels in 1910.

Exports entered as crude mineral oil in 1912 were 18,500 gallons valued at $3,964 and oil refined, 36,945 gallons, valued at $6,147. There was also an export of naphtha and gasoline of 25,791 gallons, valued at $4,261.

The decreased production has been accompanied, particularly during the past two or three years, by a very large increase in imports of petroleum and petroleum products. The total imports of petroleum oils crude and refined in 1912 was 186,787,484 gallons, valued at $11,848,533 in addition to 2,144,006 pounds of wax and candles valued at $119,520. The oil imports included crude oil, 120,082,405 gallons, valued at $3,996,842; refined illuminating oils, 14,748,218 gallons, valued at $1,022,735; gasoline 40,904,598 gallons, valued at $5,347,767; lubricating oils, 6,763,800 gallons, valued at $1,077,712 and other petroleum products 4,288,463 gallons, valued at $413,477.

The total imports in 1911 were 116,892,680 gallons of petroleum oils crude and refined, valued at $6,009,730 and 1,959,787 pounds of wax and candles, valued at $106,424. The oil imports comprised crude oil, 71,653,251 gallons, valued at $2,188,870; refined and illuminating oils, 13,690,962 gallons, valued at $722,403: gasoline, 23,338,773 gallons, valued at $1,976,032; lubricating oils, 5,308,917 gallons, valued at $806,452, and other petroleum products, 2,900,786 gallons, valued at $315,973.

The principal increases in imports have been in crude oil now used so extensively in British Columbia by the railways and in gasoline.

ELECTRICITY IN IRON AND STEEL INDUSTRY.

By J. E. Dalemont.*

The recent development in iron and steel plants has been characterized by two important features, i.e., the large direct consumption of the blast furnace gas in gas engines of large capacities and the direct drive of reversible rolling mills by electric motors.

The average consumption of coke may be estimated to one ton (1,000 kgs.) per ton (1,000 kgs.) of pig iron produced by blast furnace process and the quantity of gas produced is not less than 150,000 cubic feet.

Its average composition is:

CH_4	0.5	to	1.8
H	1.8	to	2.8
CO	21	to	26

Of this quantity about 70,000 cubic feet is used for heating the air required by the blast furnace process and the balance, about 80,000 cubic feet, is usually collected from the top of the furnace and distributed in the boiler room and elsewhere for heating purposes.

In the last ten years, owing to the progress of the gas engine industry, almost all the blast furnace gas is used directly by gas engines for generating power; it is estimated that of the 80,000 cubic feet mentioned before, about 64,000

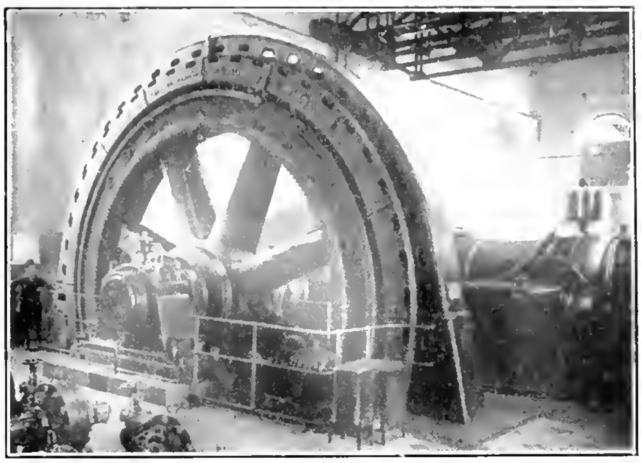

Fig. 1.—Alternator Driven by Gas Engine.

cubic feet are available for power purposes, after making allowance for the operation of the blast furnace accessories.

The advantage of this may be easily understood if we recollect that with the gas engine 28 to 30 per cent. of the calorific energy of the gas is transformed into mechanical energy, while the steam engine does not transform more than 12 per cent.

This explains also the efforts made in the last ten years to bring the gas engine construction to a very high standard. In 1900 the largest engine was not over 100 horse-power and now many engines of 3,000 to 4,000 horse-power have been built and installed, and there are units in operation of 5,000 horse-power each.

The calorific energy remaining in the gas after completion of the iron process in blast furnace practise per ton of iron produced, is approximately 1,700,000 calories for 64,000 cubic feet of gas (referred to before) which is the estimated average to be used in gas engines.

* General Manager, Engineering Works of Canada, Limited.

Some tests made with large units have shown that per kilowatt obtained the consumption of gas by a gas engine of good design is:

3,160 calories at full load
3,770 calories at 3/4 load
4,020 calories at 2/3 load

Comparing this with the steam turbine, using superheated steam of 300 degrees C. at a pressure of 160 lbs. per square inch, the average number of calories required per kilowatt produced may be estimated between 7,500 to 8,500. About 475 kilowatt hours may be generated with the energy remaining in the blast furnace gas, produced per hour and per ton of pig iron. One may easily realize the advantages with higher wages paid for help on this continent, the figures should be somewhat increased.

Owing to the somewhat different industrial and economical conditions, gas engines came, in Europe, into larger use some years before an extended application was made on this continent. The French company, "Société Alsacienne des Constructions Mechaniques," owing to its large experience in mechanical construction, has achieved in this new line a remarkable success, as demonstrated by the numerous installations of complete plants, many of them having a capacity of 10,000 and 15,000 horse-power.

Fig. 1 shows one of the alternators driven by a 94 r.p.m. gas engine, six of which were installed in the mills at Home-

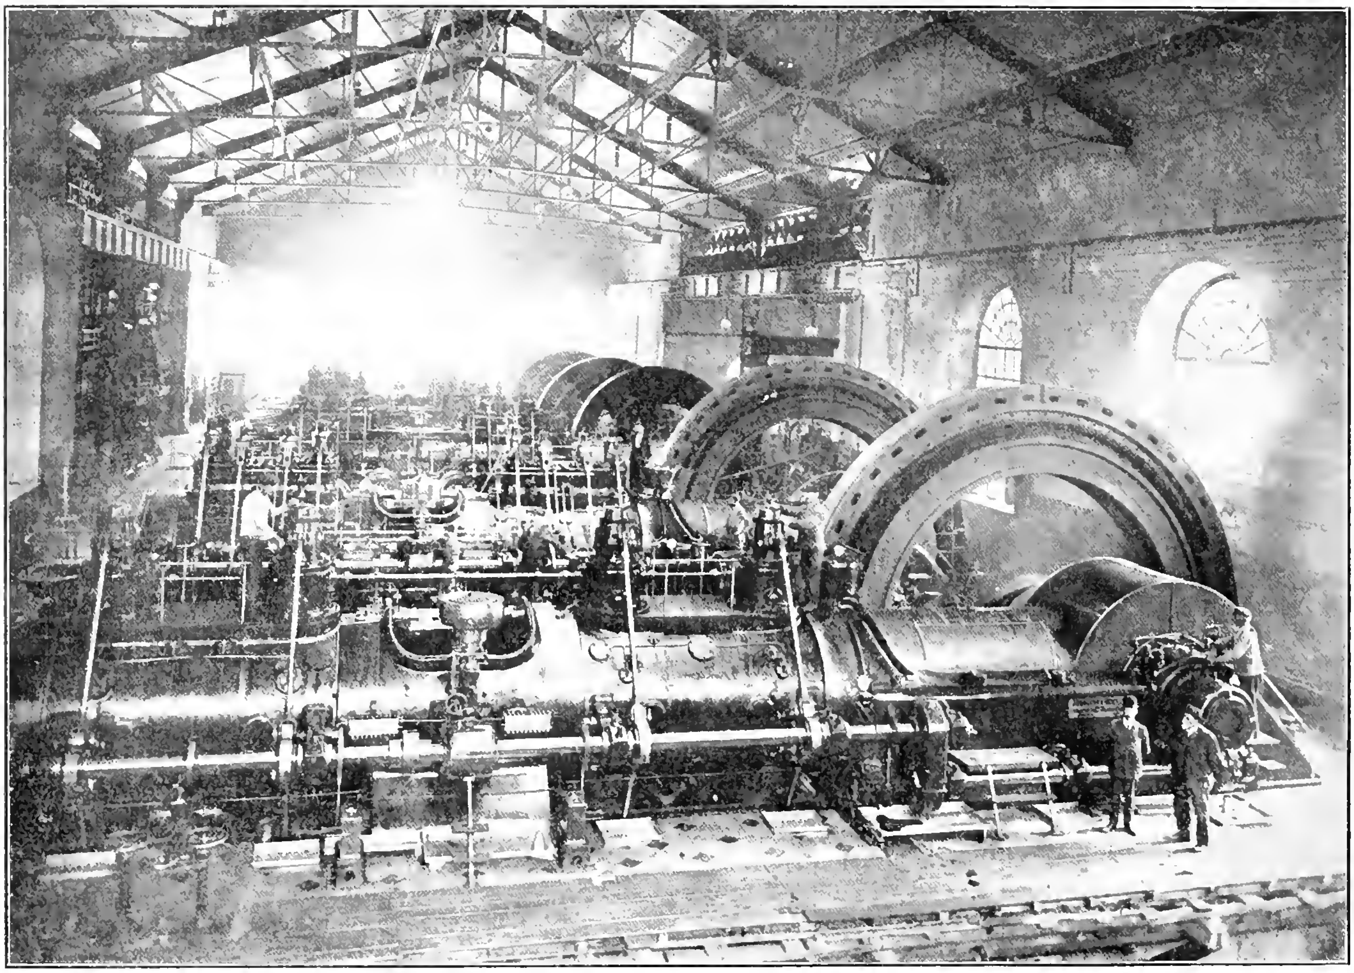

Fig. 2.—Central Station of Steel Plant.

the iron and steel plants have obtained from the new use of the blast furnace gas, generating at a very low cost electric power which is applied for lighting purposes or motors.

Similar results may also be obtained in coal mines by means of gas producers of high efficiency and the use of coal of low selling value. The gas, either drawn from the furnace or gas producers, must be washed out completely by means of special cleaners, as the cleanliness of gas is an absolute necessity for effective operation of the gas engine.

The next most important question is: What will be the total expenses per kilowatt hour at the terminals of the electric machines driven by such a gas engine? This, of course, to a large extent depends upon special conditions, which cannot be easily covered by a general estimate, but we may say that in Europe, in several large plants, the cost of production never exceeded .24 cents. With gas producers this figure is somewhat higher, about .55 cents. Of course, court. The A. C. generators have been built in the Belfort shops of the company.

The gas engines for this special application are built up to 2,000 horse-power, with two cylinders tandem, two and four tact and up to 4,000 horse-power with four cylinders tandem.

It is not intended to give here a complete description of the engines; however, some details of the distribution to the cylinders are shown which will be found interesting.

A sliding valve opens on one side the admission of air, and on the other side the admission of gas, so that gas and air can be mixed in the valve box and then admitted to the cylinders by the admission valve. This valve, as well as the exhaust valve, are operated by means of eccentrics mounted on an auxiliary shaft, which is driven by the main shaft. Its speed is half of the speed of the engine, and obtains its movement from the main shaft by means of conical gears.

The regulator is provided with an adjustment to vary automatically the speed within the limits required.

The regulator changes the composition, i.e., the gas admitted and the compression is reduced at the same time with the load, although the gas is perfectly inflammable, even for the smallest admission at no load. The valves are cooled by water circulation. The ignition can be produced either by a normal circuit at 60-100-220 volts with magnetic breakers or by a "Bosch" magneto with mechanical breakers, placed in duplicate on both sides of the cylinders in order to obtain a complete ignition. The anticipated ignition can be regulated during running.

For starting large engines, the compressed air has given the most satisfactory results. It is used at a pressure of 140 to 230 lbs. per square inch. As soon as the engine starts to run and the first explosion is obtained, the admission of compressed air is automatically suppressed on the corresponding side.

Fig. 2 shows a central station installed recently in a large steel plant by the "Société Alsacienne." The gas motors are fed with blast furnace gas and directly connected to alternating current generators. Frequently the alternators to be driven by gas engines have been built with the stator inside and the rotor outside, in order to increase the flywheel effect.

FEBRUARY PRECIPITATION.

An excess of precipitation occurred during February in Central and Southern British Columbia, Southern Alberta, Eastern Saskatchewan, Western Manitoba, Upper Ontario and the Georgian Bay region, and eastern districts of the Maritime Provinces, elsewhere the average value was not reached. The negative departures were quite marked, particularly in Vancouver Island, B.C., and the lower lake region of Ontario, where the fall was, as a rule, less than half the usual amount.

On the last day of the month the ground was snow covered throughout Canada, except on the British Columbian coast, and the depth was considerably greater than at the close of January. In the interior and north of British Columbia more than five feet of snow was on the ground. A slight covering in the neighborhood of Swift Current increased to a depth of twenty-five inches over Northern Manitoba, and to five and eight in Northern Alberta. The Highlands of Ontario, together with northern districts, were covered by over thirty inches, this being also the case in Eastern Quebec and Cape Breton Island. Good sleighing prevailed in nearly all districts during the greater part of the month.

The following table, included in the report of the Meteorological Office, Toronto, shows the total precipitation of fourteen stations for February, 1913:—

	Depth in inches	Departure from the average of 20 years
Calgary, Alta.	....	....
Edmonton, Alta.	0.60	—0.14
Swift Current, Sask.	0.30	—0.35
Winnipeg, Man.	0.60	—0.09
Port Stanley, Ont.	1.70	—1.28
Toronto, Ont.,	1.17	—1.15
Ottawa, Ont.	2.20	—0.30
Kingston, Ont.	1.50	—0.59
Montreal, Que.	2.80	—0.43
Quebec, Que.	2.90	—0.16
Chatham, N.B.	2.30	—0.49
Halifax, N.S.	3.30	—1.22
Victoria, B.C.	1.90	—1.67
Kamloops, B.C.	1.00	+0.19

WATERWORKS INEFFICIENCY.

Conservation, published by the Commission of Conservation, Ottawa, has written interestingly in regard to waterworks figures which the commission has gathered in Canada. It is as follows:—

Ninety-five and a half million dollars are invested in waterworks systems in Canadian towns and cities. The annual outlay for maintenance, exclusive of interest, amounts to $3,435,199. There are, in all, 5,215 miles of mains in use, and the total daily consumption of water passing through these, reaches 360,477,638 Imperial gallons.

These are the figures obtained by an investigation just completed by the Commission of Conservation, the results of which are being published as a report on the waterworks of Canada. They indicate something of the magnitude of the investments that are placed in Canadian public service utilities. By far the larger number of these plants are owned by the municipalities themselves, but there are a few of the smaller ones that are owned and operated by private individuals or corporations.

A Glimpse at the Details.—An examination of the details going to make up these totals present some interesting conditions. Thus, the estimated cost of supplying water varies from seven cents per 1,000 gallons for the municipalities of Nova Scotia, to 23 cents per 1,000 gallons for those of Saskatchewan, with costs in the other provinces ranging between these extremes.

In Saskatchewan, where the cost of delivery is higher than in any of the other provinces, the amount of water used is much less. In the city of Moose Jaw, for example, the daily consumption rate is only 15 gallons per head of population. All the water is metered and no flat rates are levied. The meter rates range from 10 cents to 25 cents per 100 cu. ft., somewhat below the average for the province. In the matter of meter rates, however, there is an exceedingly wide variation in Saskatchewan. In one small town these rates range from 25 cents to 75 cents per 100 cu. ft.

Waste of Water.—In eastern Canada the consumption rate is more uniform, but there are indications of considerable waste in many cities. Last year an Ontario city employed experts to ascertain the causes of waste. They found some serious leaks in mains, as well as wastage by individual users. The expert engineer, in his report, states that:—

"Water is pumped at the present time at the rate of about 190 Imperial gallons per capita daily. At least three-fourths of this water is wasted without benefit to any one. Some of this wasted water no doubt escapes from leaks in the pipe system, but probably most of it escapes from leaky plumbing fixtures in the houses and shops of the city."

One hundred and ninety gallons of water weigh nearly one ton, so that this city is each and every day in the year, pumping four and a half tons of water for each family of five persons. The average consumer may truthfully say that he is not using that amount of water, but he is paying for that amount and, if of the well-to-do class, prabably for more than that amount.

And it is not unique in this respect. There are very few cities on the North American continent in which enormous water waste cannot be found, and this despite the well-known fact that it is only necessary to install meters to put a stop to it. The Canadian who is really patriotic can not do better than consider carefully this question, particularly as far as it affects his own municipality. It is axiomatic to a waterworks expert that fifty gallons of water per head of population is ample and that—unless water is used for irrigation or similar purposes—all that is pumped over and above that amount is wasted.

CITY WATER WASTE.

There is, as has been often mentioned in this journal, a considerable waste of water in some of our Canadian cities. A report to the council of the city of Ottawa on this subject by a special committee appointed to examine into it, probably partially applies to the state of affairs in many other cities and towns. In Vol. 21, No. 8, August 24th, 1911, of The Canadian Engineer, we published a table regarding the cost of water supply in a number of Canadian municipalities of comparatively small size. It may possibly interest some readers to look this up in connection with the present article

The report reads:—

At the last Council meeting there was referred to this committee the question of water waste in the supply system throughout the city. In order that the committee may be in a position to immediately take up the consideration of this important question, I have prepared certain information which I beg to place before you along with my recommendations in the matter. I have, of necessity, gone into this question in detail so that the seriousness of the existing conditions may be quite apparent.

Rate of Consumption.—During the past year the amount of water pumped each day averaged 17.7 million Imperial gallons. The highest consumption, amounting to 20.6 million gallons, occurred on Saturday, July 13th, and the lowest consumption, amounting to 15.0 million gallons, occurred on Sunday, October 27th. On Wednesday, February 12th, of this year, the consumption amounted to 19.7 million gallons, and the daily average for the month of January amounted to 18.0 million gallons.

Pumping Capacity.—The present pumping capacity is actually about 30 million gallons per day, made up as follows:

Pump No. 1	3	million
2	3	"
3	3	"
4	5	"
5 and 6	8	"
6 and 7	8	"
Total	30	gallons per day

Of this amount 16 million gallons is accounted for by the two units, five and six, and seven and eight, most recently installed. The water wheels to operate these four pumps are in one wheel case so that when an accident occurs, as in October last, to any part of these water wheels fully one-half of the available pumping capacity is thrown out of business. This leaves the city with 14 million gallons available for its use, whereas last year the consumption averaged 17.7 million gallons per day, and as stated previously, reached as high as 20.6 million gallons on Saturday, July 13th last. Furthermore, at certain periods of the day, notably between 9 a.m. and noon, the rate of pumping would rise as high as 23 million gallons per day. Even with one of the large units being out of business, the capacity would be reduced to 22 million gallons per day. Any break-down occurring to any one of the old pumps would not materially affect the output as they are in smaller units and operate independent of each other.

It will plainly be seen that additional pumping capacity is urgently required unless an immediate and vigorous policy of waste prevention is pursued.

Consumption per Capita.—The rate per capita during 1912 was 185 gallons per day. The highest it ever reached during any year was 192 gallons per day during 1907. On February 12th last, however, the consumption amounted to 206 gallons per capita, while on Sunday, the 9th of February, it amounted to 194 gallons.

The pumping station records show that from midnight to 3 a.m. the amount of water pumped is about 85 per cent. of the average rate of pumping for the 24 hours. In other words, while the average daily consumption during 1912 was 17.7 million gallons, the rate of pumping during the night amounted to 15 million gallons per day. A very small portion of the water pumped at night represents legitimate use, nearly all being waste, and this waste so shown can be safely assumed to go on to a large extent throughout the 24 hours. If no such waste existed, then the night rate of pumping would be a small fraction of the average rate of pumping, certainly not more than 10 per cent. as against 80 to 90 per cent. as at present.

Let us consider the rate of pumping for February 12th last. The total quantity pumped that day was 19.7 million gallons, or a per capita rate of 206 gallons daily. From midnight to 3 a.m., the rate of pumping was 87 per cent. of the daily average. In other words, the quantity pumped per capita during the whole 24 hours was 206 gallons, the rate of pumping from midnight to 3 a.m. was 179 gallons per day. The figures for last Sunday, the 16th, are as follows:—

Total quantity pumped	18.3 million gals.
Quantity per capita per 24 hrs.	191 gals.
Rate from midnight to 3 a.m.	173 "

or the night rate was 90 per cent. of the average daily rate.

It is rather striking to observe that the consumption per capita per day increased from 101 gallons in 1889 to 168 gallons in 1893, an increase of 67 gallons per capita per day in four years time. I have so far been unable to find any satisfactory reason for this sudden increase.

At least 75 per cent. of this daily average is wasted without benefit to anyone. Both Sir Alexander Binnie and Mr. Allen Hazen state that 75 per cent. is wasted, and for this statement Mr. Hazen gives the following reason:—

A. There are no great manufacturing uses of water; manufacturing establishments are mainly located upon the river and obtain their water from it for manufacturing purposes and do not draw from the city works.

B. The experience of other cities which probably need to use, and do use, as much water as is used in Ottawa where systematic study has been made of the waste of water and intelligent efforts have been made to cut off such waste as far as possible, indicate that the amount actually used is not more than one-fourth as great as the amount pumped in Ottawa.

C. The night rate of pumping indicates this. Most of the actual use of water is in the day time. There is no reason why any large quantity of water should be used during midnight and 3 a.m.

From these statements, not more than 50 gallons per capita daily should be actually necessary.

Effect of Waste of Water upon the System.—The effect of allowing this enormous quantity of water to waste is that the whole waterworks system must be built larger than would otherwise be necessary. The distribution mains must be larger and the pumps must be of greater capacity. If the water is purified, the purification plant must be made larger in size and if the supply comes from a distance, such as is proposed by bringing the water from the Gatineau Hills, large additional storage must be provided for besides the enormous cost of laying main supply pipes so much larger in diameter.

No amount of reasoning can justify the necessity of this useless waste. No one derives the slightest benefit from it,

not even the oft repeated statement that it serves to flush out the sewers, because it is discharged at a steady rate, and for flushing purposes is of little value. For the benefit of all concerned it is absolutely essential that this waste should be reduced as far as possible within reasonable limits without incurring any greater expense in detecting and rectifying the waste than would be represented by the waste itself.

Waste Detection in the Past.—Until last year, practically no means were taken to to detect waste. Last summer the Pitometer Survey was carried out to detect leaks in the distribution mains, but barely one-half of the city area was covered. Leaks amounting to 4.4 million gallons per day were discovered, but this does not mean that the daily pumpage was reduced by that amount, as some of it disappeared in other leaks where the pressure was largely increased, due to the stopping of these leaks already found by the survey.

Meters.—Ottawa is practically an unmetered city as the following table will show:—

City	Year	Population	Consumption in million gallons Max.	Min.	Aver.	Gallons per capita	No. of Services	No. of Meters	Per Cent. metered	Per Cent. of consumpt. metered
Ottawa	1912	95,575	20.6	15.0	17.7	185	22,278	41	0.2	3.9
Springfield	1911	90,527	12.4	5.5	8.8	96	12,985	8,414	65	48
Lawrence	1909	81,000	....	....	3.0	44	7,416	6,633	90	59
Hamilton	1911	82,095	....	....	8.03	98	.....	....	...	....
St. John, N.B.	1911	46,016	....	....	11.5	250	6,457	193	3.2	14.5
Louisville	1910	201,000	....	....	18.4	92	35,159	2,847	8.1	33
Vancouver	1911	112,240	....	....	18.0	160	24,861	1,638	15	....

From the report made by the Pitometer Survey firm, published on page 1037 of the 1912 council minutes, you will observe that most of the leaks occur in the services and distribution mains, but that the house fixtures are not so bad as they are generally found in other cities. The following table will show what can be done in the way of waste prevention combined with metering:—

City.	Year.	Per cent. of meters.	Per capita daily consumtion gals.	Reduction per capita per day, gals.
Cleveland, O.,	1900	6	169	70
	1908	92	99	
Grand Rapids	1899	0	174	39
	1908	34	135	
Richmond, Va.	1890	1	168	55
	1907	53	113	
Milwaukee, Wis.	1891	40	112	32
	1903	90	80	
New Bedford, Mass.	1899	12	107	23
	1908	32	84	
Hartford, Conn.	1900	6	85	26
	1907	98	59	
Minneapolis, Minn.	1899	22	94	36
	1908	75	58	
Lowell, Mass.	1893	28	83	25
	1907	73	58	

How is the Water Wasted?—Water waste is divided into two heads:

a. Unknown.
b. Wilful.

In the first class we have all the leaks in the distribution mains and house services. These are known to exist, but are not visible until further examination has been made. Services that have been abandoned are generally a prolific source of waste, especially as they generally get frozen and in the spring of the year burst and continue running to waste unnoticed in many cases because of the seamy, rocky nature of the ground through which a large proportion of the services in this city is laid.

The wilful class of waste, as far [illegible] my observation [illegible] is extremely great throughout the city. By wilful waste I mean everything that can come under the term "of knowingly letting water run without anyone deriving any benefit from it."

During the first half of this month, as stated previously, the night flow averaged 85 to 91 per cent. of the daily flow. When one considers the day pressure is 90 lbs. at the pumping station, as against 80 lbs. at night, then the night flow would still be greater if the pressures were the same throughout the 24 hours. On Sundays the pumpage is only 5 per cent. less than on week days. Large quantities are wasted daily by the continued running of taps to keep them from freezing. This can be easily observed from the daily quantity pumped, as on very cold days the consumption jumps away up; for example, on February 15th, the minimum temperature was 4 degrees above zero and the consumption per capita was 190 gallons, while on February 12th, the minimum temperature was 10 degrees below zero and the consumption per capita was 206 gallons. A few examples of wilful waste may prove interesting.

A building in the city has an electric booster pump in the basement. This pump is kept running for eight hours each day, pumping water into a tank on the roof. This tank is provided with an overflow which is nearly always running to waste.

In an engineering work the water is kept running night and day in connection with a hydraulic air compressor, simply, as they tell you, to keep the pipes from freezing.

Suppression of Waste.—There are two methods which may be used for the suppression of waste:

(a) The examination of the entire distribution system, including all mains, services and internal plumbing fixtures. This can be done by certain methods which have only been developed within the last two years. Much of this waste can be located and eliminated by the use of the Pitometer, the aquaphone, etc.

(b) The introduction generally of the meter system. The wilful waste of water is very largely due to the lack of a meter system. Not only would the services be kept from running when not in use, but any defective plumbing would be immediately repaired. Again, a supply of water should be placed on a strict business footing, and so do away with such absurd cases as the following, quoted from the Pitometer Survey report:—

"The gas works on King Edward Avenue were using a large quantity of water, so a separate gauging was made for two days, and they were found to have a mean consumption of 125,000 gallons per day. At present they pay a flat rate of $245 per year, but this quantity of water at the minimum meter rate of 6 cents per 1,000 gallons would produce a revenue of $2,737.50."

The St. Lawrence Pulp and Paper Mill, on Montreal Street, was found to be using a large quantity of water. They were tested several times and found to be drawing at rates varying from 100,000 to 175,000 gallons per day.

They run both day and night and as they only pay a flat rate of $27 per year there is evidently a big loss of revenue here.

J. B. Booth & Company pay a flat rate of $1,636.86. We made a prolonged test of this plant and found that one of their services, if metered, would produce more revenue than this. This service had a steady flow of 93,500 gallons per 24 hours, which would produce, at the minimum meter rate of 6 cents per 1,000 gallons, a revenue of $2,047 per year.

Conclusions.—From the foregoing it will be clearly observed that immediate action must be taken to either increase the pumping capacity (and incidentally enlarge the distribution system) or pursue a vigorous policy of waste reduction. Undoubtedly the policy to pursue is that of waste reduction, and this is strengthened by the fact that, as the future supply for this city is likely to come from the Gatineau Hills the installing of additional pumps, which could only be of service for three years at the most, would be an unprofitable investment, and cost a great deal more than is necessary to spend on waste reduction. To be in a reasonably safe position before the warm weather comes in, it is quite apparent that immediate action must be taken.

Recommendations.—I cannot too strongly advise your committee to pursue a policy of waste prevention in preference to that of increasing the pumping capacity and enlarging the distribution mains. I submit the following recommendations for your consideration:—

1. That the city purchase two pitometer instruments and employ the necessary water survey force.

This recommendation is already in force in a large number of American cities, and also in Toronto and Montreal, where excellent work is being done. The city can be divided into districts, and by means of these instruments the flow can be ascertained from time to time, and any excessive flow can be readily observed and means taken to locate any defects which may cause same and have it repaired. These instruments can also be used to determine the pump slippage.

An appropriation amounting to $7,000 has been placed in this year's estimates for this work.

If it is decided to purchase two pitometers, then one of the pitometer survey people should be brought here for about a month to break in an assistant who will be kept on the staff for this purpose.

2. That all business premises be metered. This should include meters on all elevators, syphons, beer pumps, booster pumps, etc. That is, every service outside of an ordinary dwelling house should be metered.

3. That all public services be metered, including all buildings, parks, etc. Also, that a meter should be placed on all government services.

4. That an efficient force be maintained to carry out a thorough inspection of all pumping fixtures on all premises and dwelling houses.

5. That detailed plans be made of all the existing mains throughout the entire city.

AMERICAN RAILWAY ENGINEERING ASSOCIATION.

The annual convention of the American Railway Engineering Association will be held at Chicago, March 18th to 21st: E. W. Fritch, 900 S. Michigan Avenue, Chicago, Ill.

TEST OF WIRE ROPE FASTENINGS.*

By C. W. Hubbell.

A ⅝-in., six-strand plow-steel cable was bent around a thimble and the ends secured to the standing part by a standard ⅝-in. Crosby clip of the U-bolt type, with the nuts drawn as tightly as possible by a 12-in. wrench. The cable slipped under a load of 8,360 lb. In a second test with a new clip tightened with a 24-in. wrench, the cable slipped at a load of 10,020 lb., and after the nuts were again tightened, slipped at 12,380 lb. In a third test made with two new clips, the nuts were tightened under a load of 6,000 lb. with a 12-in. wrench, and the load was increased to 21,710 lb., which broke the cable where it was in contact with the lower U-bolt. As the rated ultimate strength of the cable was 36,000 lb., it was thought to have been weakened by the distortion under the U-bolt, which was set in contact with the standing part, while the head took bearing on the free end. It was assumed that in practice the head of the clip should always be placed on the standing part of the cable and the U-bolt on the free end.

A 95-lb. cast-iron clamp, 33½ in. long, made in two pieces, with grooves fluted to receive the cable, and connected by five 1-in. bolts having a theoretical holding power of 19,500 lb., was placed on a 2-in. seven-strand galvanized steel-wire cable. The bolts were drawn as tight as possible by one man with an 18-in. wrench, and the cable slipped under a load of 12,000 lb. The nuts were tightened by one man with a 30-in. wrench, and a slip occurred under a load of 12,500 lb. The nuts were again tightened, and the third slip occurred under a load of 16,500 lb. The clamp was removed and replaced on the cable in a new position, and the nuts tightened by two men with a 30-in. wrench. The cable slipped under a load of 17,800 lb., and in successive tests under 12,700 and 15,000 lb. When tightened with three men on the same wrench, turning each nut from one-eighth to three-eighths of a revolution, the cable slipped at a load of 19,300 lb. In the last test the groove in the clamps had a diameter of two inches, permitting the cable to rest on the bottom of the groove.

A lighter clamp of different design had a groove 1¾ in. in diameter, designed to develop a wedge action increasing the bolt pressure when the clamps were forced together and the cable distorted enough to bear on the bottom of the groove. The clamp was 12 in. long, weighed 47 lb., was provided with five ¾-in. bolts and had a theoretical ultimate strength of 22,650 lb. for each half. The bolts were fastened by one man with a 24-in. wrench and no slip was apparent under a 10,000-lb. load. The nuts were tightened and the load increased to 20,900 lb. without apparent slip. The clamp was removed and found practically uninjured.

It was concluded that, first, where more than one clamp is necessary they should be placed as close together as possible, in order that the necessary adjustment of cables to bring them all into action shall be as light as possible; second, the clamp bolts should be tightened from time to time as the load is applied; third, the safe holding power of a cable clamp may be taken at about 3,750 lb. per sq. in. or area of the bolts which secure the two halves of the clamp.

*Abstract of address presented to to Philippine Society of Civil Engineers.

COAST TO COAST.

Ottawa, Ont.—Canada's mineral production last year was valued at $133,127,489, an increase of $29,906,405, the highest on record, or twenty-nine per cent. greater than the previous year. There was an increased output in the value of every mineral and in the quantity of all but silver, which decreased two per cent. Ontario still leads with a total production of $51,023,134.

Edmonton, Alta.—Seven hundred and thirty-one new companies, with a capitalization of $91,351,883 were incorporated in Alberta last year, as compared with 573, with a capitalization of $72,455,100 during 1911. Since the incorporation of the province there have been 2,300 companies incorporated in the province, with an aggregate capital stock of $267,304,508.

Ottawa, Ont.—An agreement has been reached between the Algoma Steel Company and the government in regard to the duty rebate made to the Algoma Steel Company on 75,000 tons of rails imported into Canada last summer. The capital were allowed a refund of half duty on 50,000 tons for the G.T.R. and 25,000 tons for the C.P.R. Hon. Frank Cochrane pointed out that two big railways have 500 miles graded and ready for rails which they cannot get, and which the company say they cannot supply at such short notice.

Fredericton, N.B.—A demand in the form of a petition signed by 5,000 people in all parts of the province of New Brunswick, asking for better roads, has been presented to the government by the Good Roads Association. The premier said that, while he did not agree with the idea of building the trunk roads outlined in the Good Roads Association programme, it was the aim of the government to expend $100,000 a year on fixing the "bad spots." He also suggested that a highway engineer be appointed to make specifications for the repair and improvement of these bad spots, so that in a few years the condition of the highways throughout the province would be improved.

Edmonton, Alta.—Landscape Architect Morell has designed a civic centre for Edmonton. Property owners of this land proposed by Architect Morell in his scheme have agreed to sell it to the city at a cost of $2,567,000, to be paid in forty-year debentures bearing five per cent. interest. The commissioners, in reporting on the matter, declared that in their opinion this was the logical location for a civic centre, but that the time is not opportune for the city to invest two and a half millions in a project of this kind. They therefore recommended that the promoters of the scheme take the matter up again at a later date, and submit more reasonable prices.

PERSONAL.

SIR JOHN JACKSON, the well-known engineer and contractor, of London, is making a tour of Canada.

J. H. LYONS, who was for some time employed at the filtration plant at Toronto Island, has accepted a position with the National Paving Company, Regina. He will assume his new duties at once.

J. W. TURNER, former superintendent of waterworks of the city of Strathcona, has, since the amalgamation of Edmonton and Strathcona, been appointed superintendent of waterworks for the Amalgamated cities.

MASON H. BAKER, B.A.Sc., D.L.S., A.M.Can.Soc. C.E., graduate of the Faculty of Applied Science, Toronto University, in 1906, has resigned his position as city engineer of St. Thomas to accept a similar position in Prince Albert, Sask.

MR. R. H. MERRIMAN has resigned his position with the B. Greening Wire Company as regards active connection with the firm. Mr. Merriman, it is understood, has decided to go into the agency business. He still retains his financial interest with the company.

PHILIP J. DUFF, A.M.Can.Soc.C.E., had joined the staff of George F. Hardy, consulting engineer, 309 Broadway, New York. Mr. Duff has recently completed the work on the construction of a new thirty-ton sulphate pulp mill for the Dryden Timber and Power Company, Limited, of Dryden, Ont.

MR. J. S. DOBIE, B.A.Sc., graduate in civil engineering of Toronto University in 1895, was elected president of the Ontario Land Surveyors' Association at their annual convention held recently. Mr. J. W. Fitzgerald, of Peterborough, was elected vice-president and Mr. L. V. Rorke re-elected secretary-treasurer.

MR. WILLIAM H. CONNELL, Assoc.M.Am.Soc.C.E., Chief, Bureau of Highways and Street Cleaning, Philadelphia, Pa., on March 4th delivered an illustrated lecture on "Organization of Municipal Highway Departments," before the graduate students in Highway Engineering at Columbia University.

MR. A. A. KINGHORN, B.A.Sc., of the University of Toronto, who has been for seven years in the Works Department of Toronto, and is at present superintendent of the construction of roadways, will sever his connection with this department on March 22, to take a position as manager of the Asphaltic Concrete Company of Toronto, Limited.

H. VICTOR BRAYLEY, who for some time past has been connected with the Transcontinental Railway at Ottawa, has accepted the position of general manager for Gunn, Richards & Company, New York and Boston, whose business is that of efficiency engineers. Mr. Brayley has opened a temporary office in Ottawa for two or three months before moving the Canadian head office to Montreal. Mr. Brayley has been secretary of the Ottawa branch of the Canadian Society of Civil Engineers for three years.

SASKATCHEWAN LAND SURVEYORS.

The annual meeting of the Saskatchewan Land Surveyors was held recently at Regina. The feature of the meeting was a paper on "The Selection of Bridge Sites," by A. P. Linton, B.A., B.Sc., assistant chief engineer of the Department of Public Works. Another excellent paper, but one of a more technical nature, was read by E. H. Phillips, D.L.S. and S.L.S., district surveyor and engineer. Cyrus Carroll, one of the oldest surveyors in the province, was made a life member of the association.

CANADIAN MINING INSTITUTE.

The 15th annual meeting of the Canadian Mining Institute was held at Ottawa recently, about 250 delegates from every part of Canada being in attendance.

The meeting was opened by H.R.H. the Duke of Connaught, who referred to the vast importance of the mining industry in the Dominion, which was, he felt sure, merely on the threshold of future possibilities.

Dr. E. A. Barton was elected president, Mr. Thos. Coutley 1st vice-president and Mr. G. G. S. Lindsay 2nd vice-president.

THE IRON AND STEEL INSTITUTE.

The Iron and Steel Institute, London, will hold its annual meeting at the Institution of Mechanical Engineers, Westminster, on May 1 and 2. At this meeting the Bessemer gold medal will be awarded to Adolphe Greiner, general director of the Societé Cockerill, Seraing, vice-president of the institute. The annual dinner will be held at the Hotel Cecil on May 1.

THE AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.

The fourth annual meeting of this society was held in the United Engineering Societies Building, New York City. The following officers were elected: President, Mr. H. J. Cole: 1st vice-president, Mr. E. Wigmann: 2nd vice-president, Mr. Geo. T. Clark.

The evening session was held at 8 o'clock and was opened with an address by the incoming president, Mr. Howard J. Cole, of Montclair, N.J. Mr. Edward F. Croker, ex-chief of the New York Fire Department and president of the Croker National Fire Prevention Engineering Company of New York City, delivered an illustrated lecture on "Fire, Its Effects and Its Prevention."

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, T. S. Young, 220 King Street W., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Dècary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, P. Pardo Wilson. Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

An Engineering Weekly

THE GARRISON CREEK STORM OVERFLOW SEWER IN THE CITY OF TORONTO.

By RAY R. KNIGHT, C.E.*

The occurrence and recurrence of flooding during heavy rain-storms, due to the inadequate provision of sewers in many parts of Toronto, necessitated a complete system of storm relief sewers. The sewer department of the city engineer's office took the matter up and a scheme was laid down and estimates provided for the purpose of putting a by-law before the ratepayers on January 1st, 1911.

The scheme, which has been partly carried out, follows mainly the lines of the original lay-out. Some deviations, however, were found advisable when details and construction matters were gone into.

The sewerage of Toronto is on the combined system. The general topography of the city is a steadily rising, fairly even surface from Lake Ontario at the south to the ridge about 2½ miles north. The surface is intersected at intervals by natural creeks running from north to south in more or less direct lines, the notable exception being Rosedale Ravine, which follows a southeasterly course to the Don. Steps were not taken in the past to reserve, for purposes of main sewers, these natural creeks, excepting the Garrison Creek and Rosedale Ravine; the general sewerage scheme consisted of a number of sewers flowing into the lake and bay along streets running north and south. The Garrison Creek sewer, however, provided a good example of the treatment which could have been adopted in other parts of the city, with King, Queen, College and Bloor Streets as intersecting parallels. The Garrison Creek sewer is, at the present time, inadequate for the removal of the storm water from the

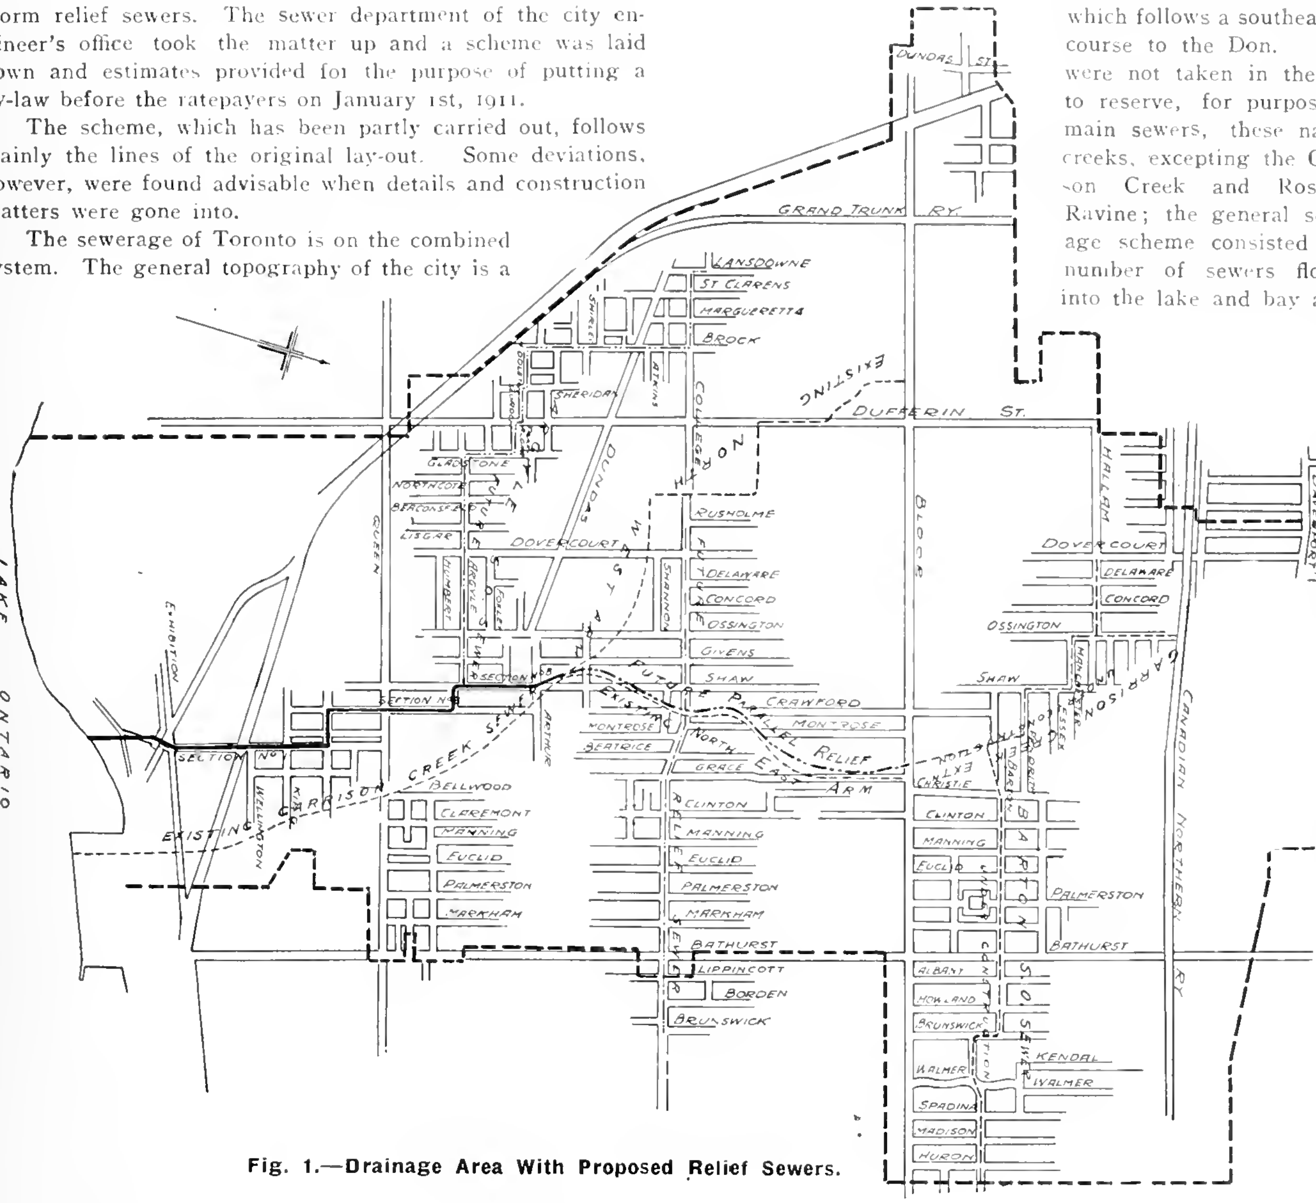

Fig. 1.—Drainage Area With Proposed Relief Sewers.

* Chief designing engineer, Sewer Department, Toronto. Since writing this article Mr. Knight has gone to Fort William, Ont., as city engineer.

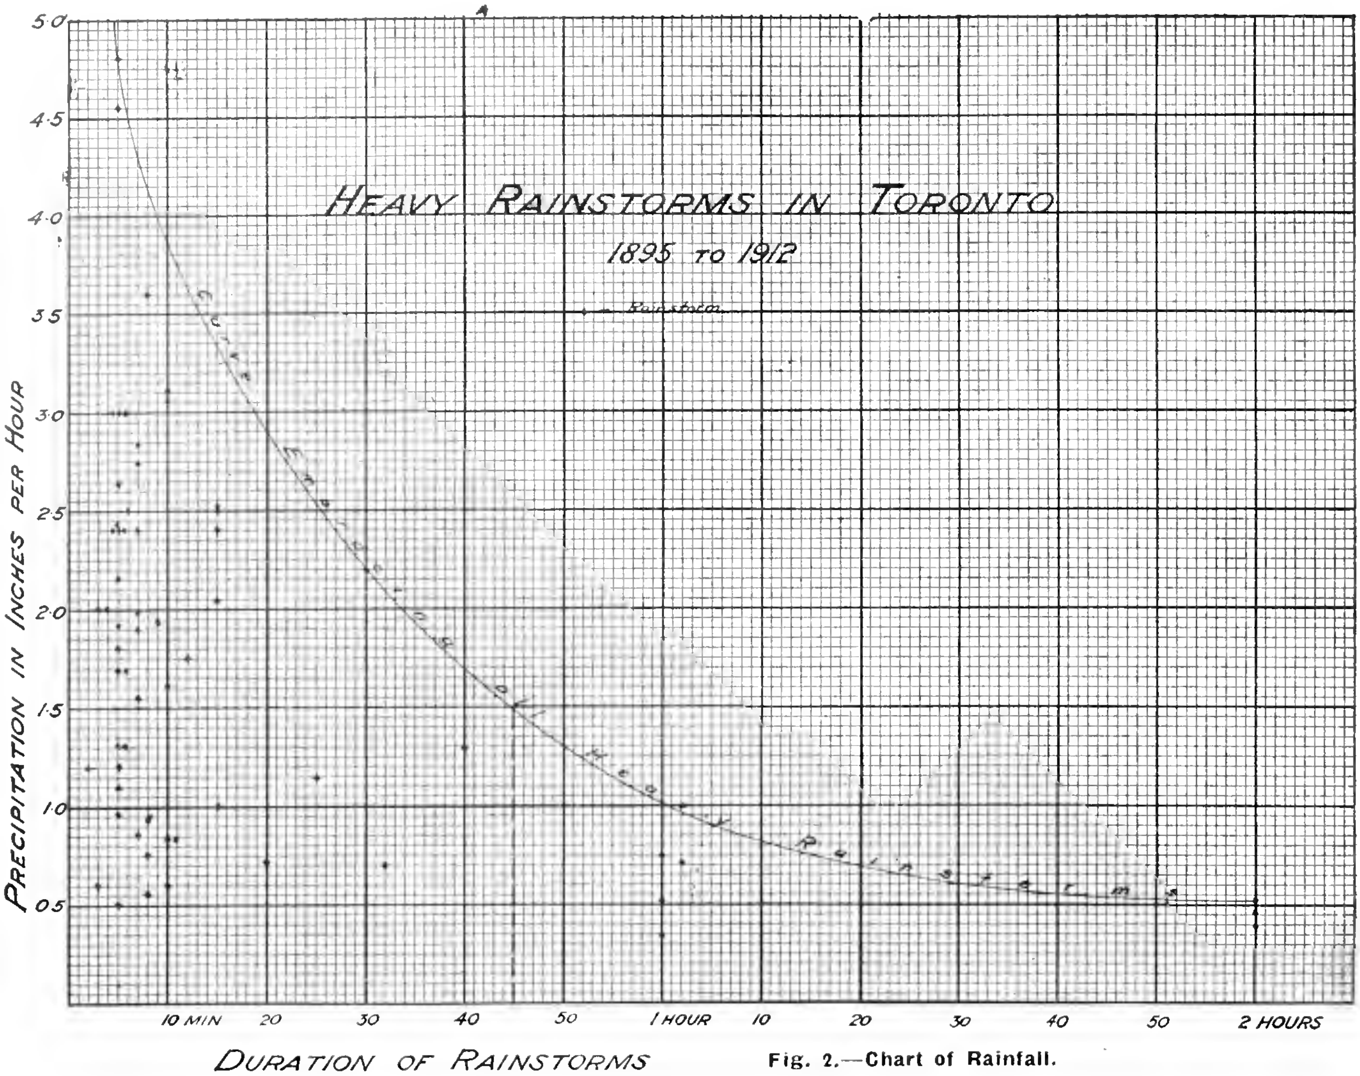

Fig. 2.—Chart of Rainfall.

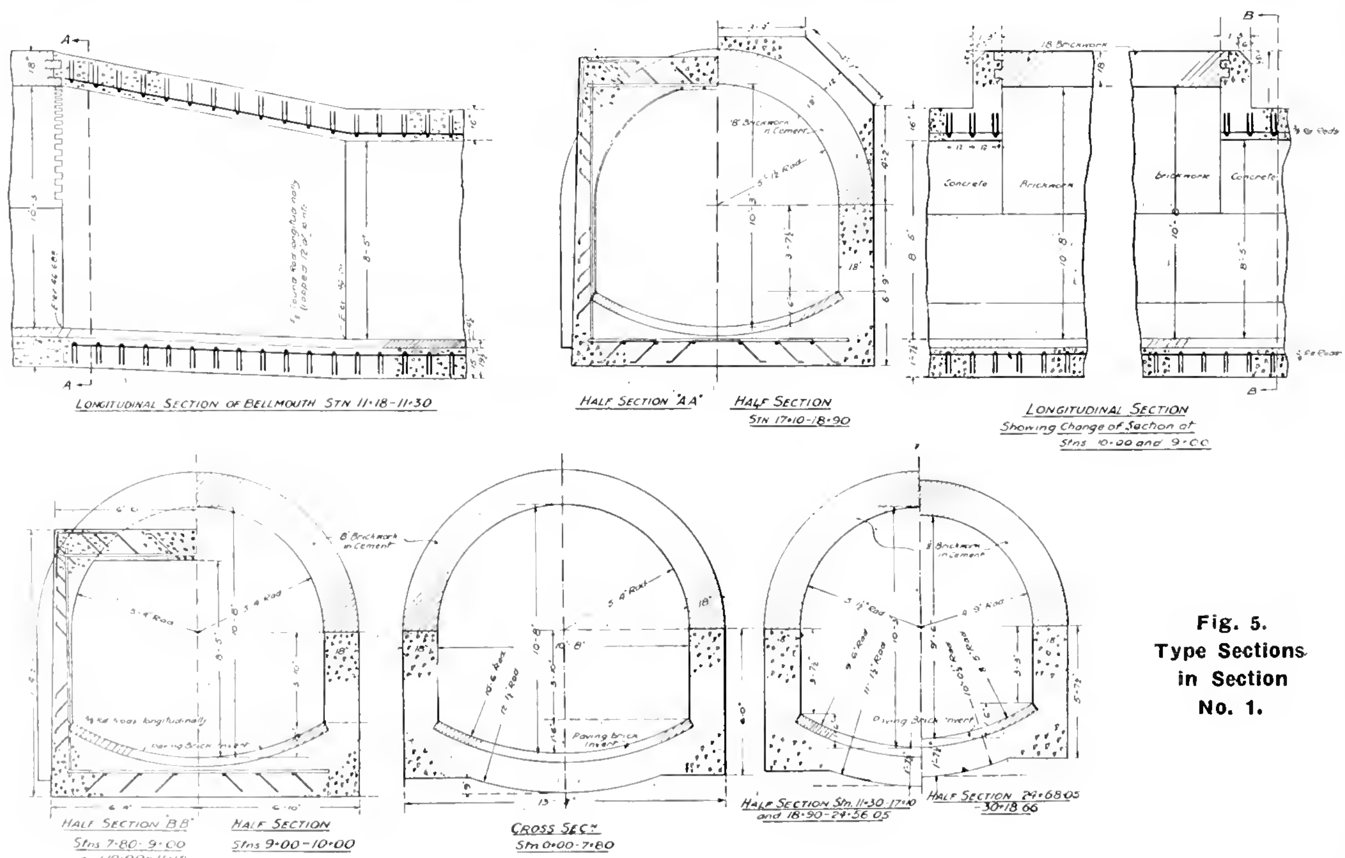

Fig. 5. Type Sections in Section No. 1.

drainage area which has from time to time been extending both northerly and westerly. The outcome being the backing up and flooding of the parallel intercepting sewers, themselves much overtaxed, and the consequent flooding of tributary sewers.

Relief had to be provided before the northerly areas were developed and sewered. It was, therefore, decided to relieve the Garrison Creek sewer at its bifurcation to the northeast and northwest, just north of Arthur Street.

It is the intention of this article to describe the design of this relief sewer, called the main Garrison Creek storm overflow sewers. Sections 1, 2 and 3.

In order to design the relief sewer the following particulars had to be ascertained:—

(1) The existing and probable drainage area.

(2) The locations, elevations and drainage areas of parallel intercepting sewers.

(3) The rate of precipitation.

(4) The rate of absorption, etc.

(5) The probable discharge due to heavy rainstorms.

Drainage Area.—Fig. 1 shows the drainage area with the proposed relief sewers.

Rate of Precipitation.—In order to fix upon a rate of rainfall for which provision would be necessary, the diagram shown in Fig. 2 was prepared. The heavy rainstorms since 1895 are plotted by "diamonds" on this chart, and a curve including all drawn in. It was found that 45 minutes was a fair average for concentration in the intercepting parallels, and that being the case, reference to the chart will show that a rate of 1½ inches per hour is indicated on the curve drawn. This rate was taken in all calculations for the storm sewers.

Rate of Absorption.—The rate of absorption was fixed arbitrarily for certain areas of the city from general knowledge of the localities, based upon a series of actual surveys, made for the purpose of ascertaining the proportional relation of impervious to pervious areas. The result of these surveys is given below:—

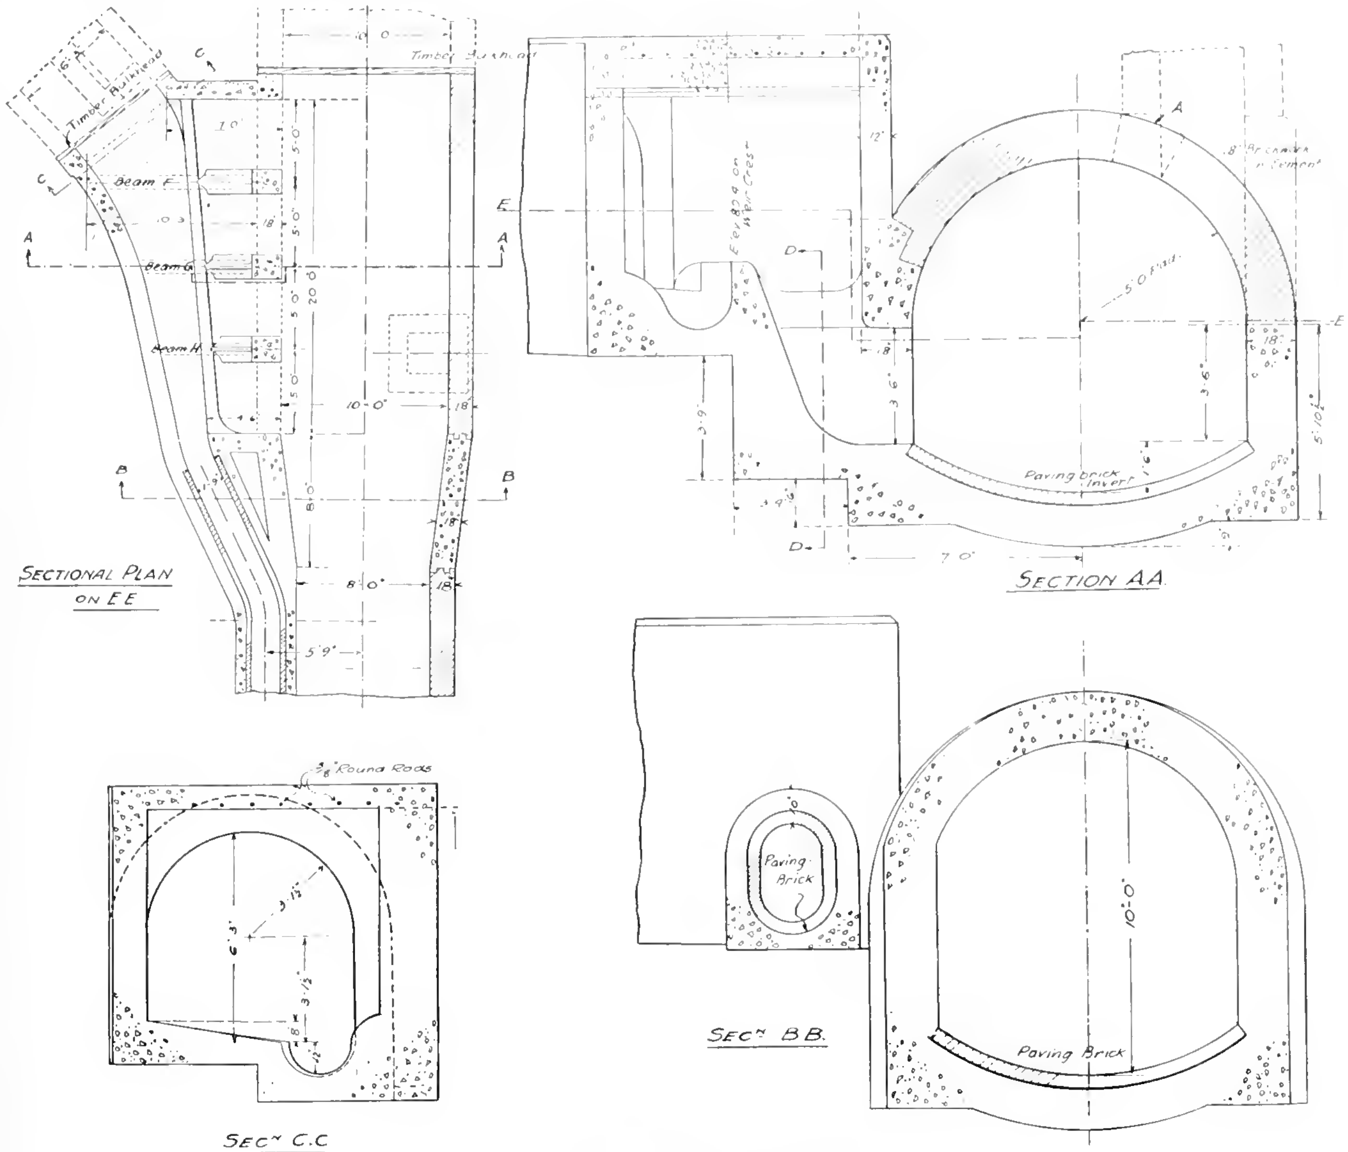

Fig. 8.—Weir Chamber, Argyle Street.

Impervious Areas—Toronto.

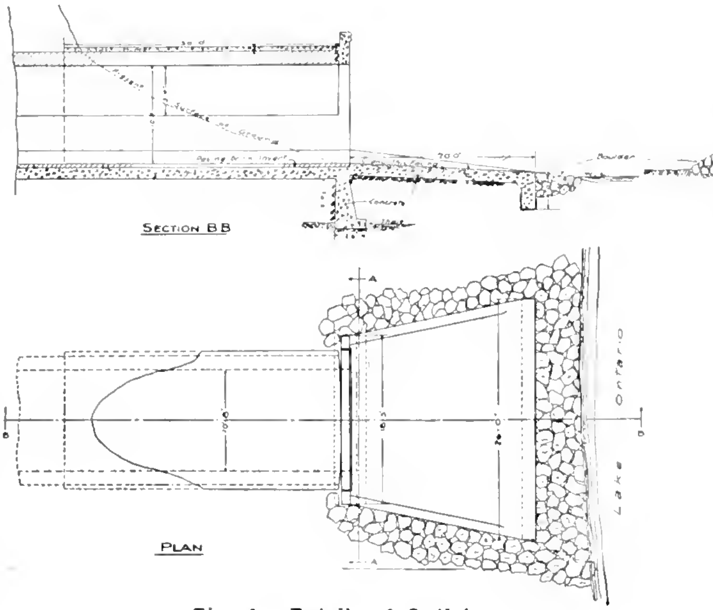
Discharge Due to One and One-half Inches Rainfall.—The diagram shown in Fig. 3 was prepared showing the discharge in cubic feet per second at all points along the line of the proposed storm relief sewer, due to a rainfall of 1½



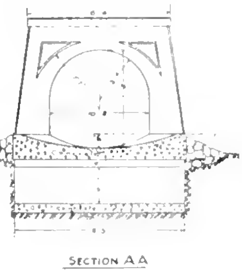


Fig. 4.—Details of Outlet.

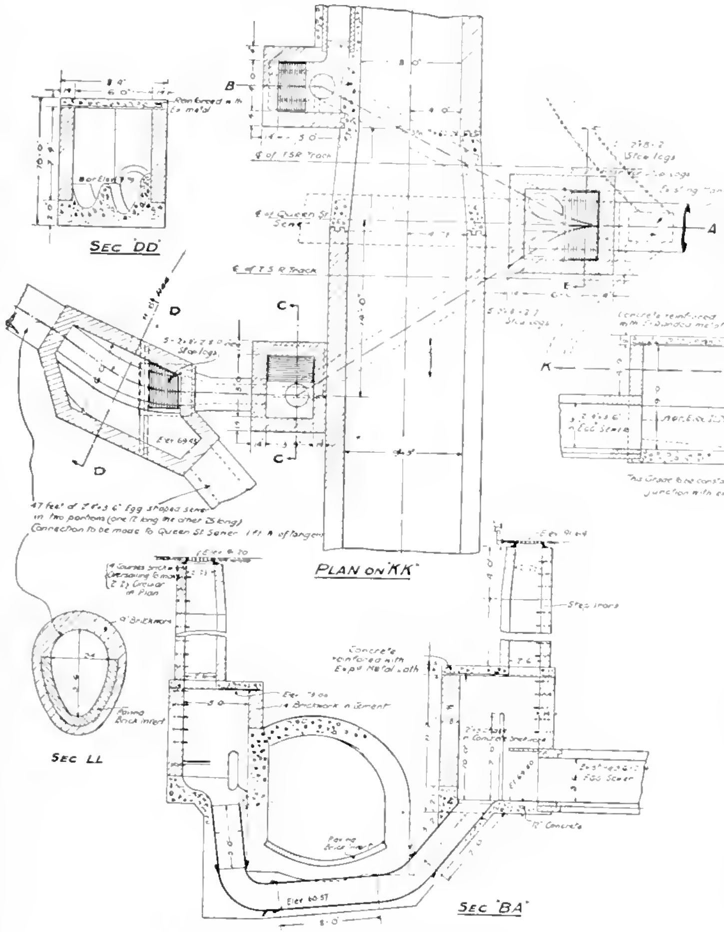

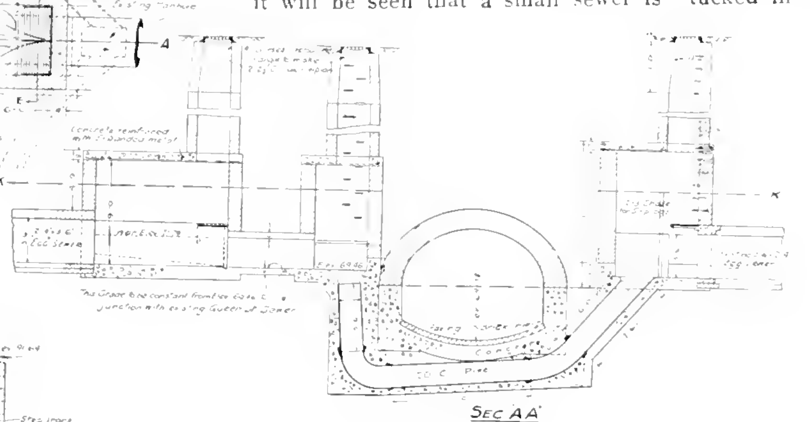

Fig. 7.—Syphons at Queen Street.

inches per hour with absorption varying between 30 per cent. and 50 per cent.

Design of the Relief Sewer.—At the point selected for relief of the existing Garrison Creek sewer it was found that a quantity equal to 945.76 cubic feet per second had to be taken by the relief sewer which, on its course to the south, receives additional discharges until at it outlet a capacity of 1,296.90 cubic feet per second is required.

Generally speaking, grades are good, and give high velocities—much above the orthodox sewer requirements. However, these sewers are idle most of the time, so that matters of wear and tear, due to high velocities, do not figure.

Starting at the lake (south end) at the 0+00 of Section No. 1, a head-wall is provided for the 10-ft. 8-in. by 10-ft. 8-in. arch and invert culvert. This headwall with the apron is not designed as a permanent structure in view of a probable future extension into the lake to the sea-wall limit. Fig. 4 gives the details of headwall and apron. Fig. 5 shows the type sections adopted in Section No. 1. The flat top section was necessary in order to pass under the railway tracks and to get a minimum 4 feet of cover from top of sewer to base of rail, as required by the Railway Board, order No. 13494.

With the exception of the portion across the railway tracks the culvert was designed for tunnel work, and is being executed in that manner.

At King Street the high level interceptor had to be crossed, and special invert castings provided in order to keep grade in both sewers.

The existing sewers and proposed relief sewers draining into Section 2 presented difficulties which have been overcome in the manner shown in Figs. 6 and 7.

Fig. 6 shows the type of culvert adopted in this section of the work. From station 11+54 to 23+73 it will be seen that a small sewer is "tucked in" the wall of the culvert. This sewer has a flow in the same direction as the culvert, but as at a smaller grade. The type shown is for tunnel execution, the complete arch section of the top exterior being the main feature. At Queen Street (see Fig. 7) two syphons had to be constructed to take the sanitary sewage across the line of storm sewer. The grade of the existing Queen Street sewer did not permit of a sufficient hydraulic head being given so that excessively large diameter syphons had to be designed so as to permit any undue loss of head. A small overflow chamber is shown relieving the Queen Street sewer at this point.

At Argyle Street and Shaw Street (the end of Section 2) a large weir chamber is provided, as shown in Fig. 8. This is the overflow chamber for a proposed intercepting combined sewer, the sanitary flow from which is taken in the small sewer in the wall of the culvert to Queen Street and discharged there into the existing sewer via the syphon (to the north) shown in Fig. 7.

Section 3 completes this sewer and comprises a culvert, as before, with an overflow chamber at the existing Garrison Creek sewer. This chamber is shown in Fig. 9. The outlet of the existing sewer is throttled by adjustable stop-logs, so as to prevent any excess of storm water passing down. The sanitary sewage is prevented by the weir from running into the storm overflow sewer. Provision is also made in this chamber for a future sewer, which will parallel the existing one from the north.

Contracts for the whole of this work have been let and work is in progress all along the line. Tunnelling is general throughout, although it is probable that the north end of Section 3 will be executed in open-cut on account of made ground which is revealed by the borings.

Alternative tenders were called for brickwork arch, concrete arch of same dimensions as brick, and reinforced concrete arch. In every case the concrete arch (without reinforcement) was adopted as lowest in cost.

The borings throughout gave indications of good hard clay. In Section 2 water was revealed in small quantities and shale is reached.

The total contract cost of the sewer, which is 6,909 feet long, is $318,000.

Provision of the sum of $125,000 has just been made for the paralleling of the existing Garrison Creek sewer from the north end of the work described here to Bloor Street, completing the necessary relief and connecting up the whole system of storm overflow sewers for this particular drainage area.

CANADA'S MINERALS.

The production of the more important metals and minerals is shown in the following tabulated statement in which the figures are given for the year.

	1912 Quantity.	1912 Value.	Increase or decrease in value.
Copper ....Lbs.	77,775,600	$12,709,311	+$ 5,822,313
Gold ....Ozs.	607,609	12,559,443	+ 2,778,366
Pig iron ....*Tons	1,014,587	14,550,999	+ 2,243,874
Lead ....Lbs.	35,763,476	1,597,554	+ 769,837
Nickel ....Lbs.	44,841,542	13,452,463	+ 3,222,840
Silver ....Ozs.	31,931,710	19,425,656	+ 2,070,384
Other metallic products	....	982,676	+ 571,344
Total..............		$75,578,102	+$17,478,958
Less pig iron credited to imported ores	987,232	14,100,113	+ 2,406,392
Total metallic		$61,177,989	+$15,072,566
Asbestos and asbestic ....Tons	131,260	2,979,384	+ 36,276
Coal ....Tons	14,699,953	36,349,299	+ 9,881,653
Gypsum ....Tons	576,498	1,320,883	+ 327,489
Natural gas	....	2,311,126	+ 393,448
Petroleum ....Brls.	243,336	345,050	— 12,023
Salt ....Tons	95,053	459,582	+ 16,578
Cement ....Brls.	7,120,787	9,083,216	+ 1,438,679
Clay products	....	9,343,321	+ 983,388
Lime ....Bush.	7,992,234	1,717,771	+ 200,172
Stone	....	4,675,851	+ 347,094
Miscellaneous non-metallic	....	3,364,017	+ 1,221,175
Total non-metallic..		$71,949,500	+$14,833,929
Grand total		$133,127,489	+$29,906,495

*Short tons throughout.

CONCRETE IN RAILROAD WORK.

The railways of Canada, in their yearly expansion in road buildings, have had, among other things, to add to each year's expenditures for concrete work. In a paper before the National Association of Cement Users, at Pittsburg, Mr. M. S. Long deals with the use of cement by the railways as follows:—

"Concrete in Railroad Work," is a subject so broad that it is difficult to tell where to begin. Concrete, to this generation, seems a new material, but history tells us that it is a very old one, having been used in the Roman baths and in concrete bridges still in use in Italy, which were built 1,500 years ago.

For many years the secret for making concrete was lost, but concrete is now used probably more than any other building material, and is considered, by some, as being infallible and a substitute for every other building material; but it must be given proper treatment or it will be sure to cause trouble. The railroads, which are, to my mind, the master builders, are using millions of barrels of cement every year, and each succeeding year sees them using concrete for a greater number of structures.

Concrete, properly used, is perhaps the most permanent building material we have in use to-day, but because it is such, and because the railroads are really in their infancy, there are some structures they hesitate to make too permanent. As stated before, we have examples of concrete structures 1,500 years old. Compared to that, the first railroad station in Chicago was built near the junction of the present Canal and Kinzie Streets, in the fall of 1848. That was only 64 years ago, and perhaps that building would be good enough for use to-day, had progress not caused it to be replaced many times by larger structures, better adapted to the handling of the increased business—even in 12 years the depth of our engine houses has increased from 75 feet to 95 feet, and now we are making plans for a house 115 feet deep. And so, in building our railroad structures of concrete, though we feel that they should last even longer than the 64 years referred to, who can say that they can be operated economically even 25 years hence. Therefore, were it not for the demands of progress, I believe that the majority of all buildings would be built of concrete; but the tearing down of concrete is difficult—therefore, expensive and wasteful, because the salvage cannot be re-used to advantage.

For foundation work, concrete plain or reinforced, is almost always used, because for that character of work it is cheaper, stronger, more flexible and can be built in a shorter time than with any other material.

We have used it for coaling stations, where 800 tons of coal is stored over main tracks, and for this character of building it is very satisfactory.

We have used it for water tanks, where a large storage is desired and high pressures are needed. We have built three tanks of 100,000 gallons capacity, and with one of them we had considerable trouble. This tank is 24 feet in diameter, 80 feet high, and not only furnishes water for the engines but is our supply for fire protection. From the base of rail to the water line in the storage compartment is 50 feet. This tank was finished late in December, and was filled to within 4 feet of the top a few days after it was completed, and on the day it was filled the temperature fell to zero. It so happened that orders were not issued for engines to take water at this tank until about two days after it was filled. We found that, in the meantime, a layer of ice had formed—it being about 18 inches thick around the sides but in the centre it was not more than 1 inch thick. The water was

used until the gauge showed the tank empty, and about this time the weather had moderated and the ice fell. In breaking loose, it tore the waterproofing off and this allowed the water to percolate through the walls and freeze on the outside—the ice collecting in chunks weighing a ton or more. When the weather moderated, this ice fell off and we found that the walls were damaged very little, and with an application of waterproofing on the inside and a coating applied to the exterior with a cement gun, the tank held water satisfactorily, and we have had no trouble with it since.

From the experience we gained, we would recommend that concrete structures of this character be coated inside and outside with waterproofing, and be allowed to cure before water is put in. Our trouble was caused, no doubt, by the concrete not being protected until it had thoroughly cured, and as there was still moisture in it when the zero temperature struck it, the water in the concrete froze, and when it thawed it left pores through which the water could escape.

The other two tanks are 53 feet high, and we have two reinforced concrete reservoirs, 55 feet in diameter, 12 feet high, built on the ground—the latter each hold 200,000 gallons and are giving satisfactory service. They are, each one, coated inside and out with waterproofing compound.

We have built reinforced concrete cinder pits, where hot cinders are dumped and then drenched with cold water. Here we find that concrete must be faced with vitrified brick, as alternate heat and cold cause it to spall. We have tried using slag as a substitute for stone in these pits, and find it an improvement, but it is not altogether satisfactory.

We have built pump houses, where the pumps are placed in a water-tight compartment below the water level on the outside.

Also, subways for passengers going from one platform to another. The one I have in mind being below the water level, so that it was necessary to waterproof against the water pressure. In this instance, we kept the water down by pumping and laid a cinder concrete base to receive the "Membrane" method of waterproofing. After the work was completed, the water developed a greater head than we had figured and some leaks developed. In repairing them we found that the cinder concrete, which was made from soft coal cinders, had not set up. We have since learned that others have had experience similar to ours, and upon testing it, we find that the soft coal cinders contain a great deal of sulphur. This is not true of hard coal cinders, and the latter are the only kind that should be used in concrete.

We have built one reinforced concrete engine house, as we are reasonably sure that this structure will be permanent, but we used a wood roof, as we felt that the escaping steam would condense on the cold concrete ceiling and drip off on the engine jackets.

We have built a reinforced concrete grain elevator for the storage of grain, and although the concrete was mixed rather wet, we had considerable trouble with dampness at times during hard, steady rains. We applied waterproofing to the outside of the walls and since that time have had no trouble from dampness.

We are now building an eight-story reinforced concrete warehouse in New York City, and do not expect to waterproof the exterior walls above the ground line in any way, for we believe that in a structure of this character that by careful mixing and careful placing and working the mass into place it can be made sufficiently waterproof of itself.

In conjunction with the Lake Shore & Michigan Southern Railway, we built a passenger station at Gary, Ind., which is practically all concrete. The building is Classic in design and the lines and shapes are the same as if cut stone was to be the material used.

During the past year we found that we could buy watch boxes and telephone booths, of reinforced concrete, cheaper than we could build them of wood, and we have now adopted the concrete ones as our standard.

In making plans for some small shop buildings, within the past year, we specified wood construction, also steel frame covered with metal lath, plastered both sides with cement mortar, making the concrete wall, approximately two inches thick, and were agreeably surprised to find that the bids for the steel frame and concrete were as cheap as the wood construction, and, of course, concrete was adopted.

In our track elevation work at Chicago, concrete is the principal material used, and the results obtained are very satisfactory, and the design and general appearance of that part of the work through the parks has been very favorably commented upon by the Park Board.

There are many reasons why concrete is chosen by the railroads in preference to other materials, some of them being as follows:—

1. Its rigidness, especially in buildings containing machinery.—Vibration in a properly constructed concrete building is negligable.

2. Its low cost of maintenance.—With a good concrete structure the maintenance should be very low, as the structural parts should last indefinitely.

3. Its fireproofness.—We consider our reinforced concrete structures so nearly fireproof that we carry little or no insurance on them. We do, of course, carry insurance on the contents.

4. Its waterproofness.—Reinforced concrete, when properly mixed, can be made practically waterproof against small pressures. It should be mixed wet and well worked into place to obtain this result.

5. And perhaps most important, is the cost.—Compared to a structural steel fireproof building, its cost is lower but it is more expensive than ordinary mill construction, and it is up to some of you to design a flexible form that will help cheapen the cost—a form that can be used over and over again and flexible enough to fit any wall or column.

There are a number of other things that you, who are making a life work of concrete in its various phases, should give consideration. It would be universally used as a wearing surface for freight house floors, passenger platforms, etc., were it not for the fact that its surface is so likely to become chipped and broken, and once broken it wears very fast. We are now making some tests with ironite worked into a rich mixture for wearing surface, and while this increases the wearing qualities, it is not as satisfactory as we would like. We also find that concrete floor surfaces dust badly, and it is necessary to resort to the use of linseed oil and shellac, or to hot silicate of soda, which eliminates the dust for a time.

Another adverse feature of concrete is contraction cracks. As concrete cures it has a tendency to crack, and this gives it the appearance of having veins, especially so where moisture has had a chance to enter through these small cracks. Where the mass of concrete is waterproofed this is a serious proposition, and we would like very much to have this problem solved, as I am sure many more buildings would be constructed with a concrete wearing surface, were it not for the fact that these incipient cracks ruin the appearance of the structure. A great deal of this is, no doubt, caused by finishing the surface with a very rich mixture—should it be necessary to patch voids in the surface we specify that the mixture should be no richer than the mass. We specify our concrete surfaces to be finished by rubbing with a concrete brick. We also find that where cracks occur the moisture entering the mass starts a chemical action which results in the surface being ruined by efflorescence.

Another step forward in the use of concrete would be to make it in colors. This does not mean by painting, but the coloring matter should be mixed, or probably ground, with the cement, and great care must be taken to get each batch properly proportioned. This is only a suggestion, as chemical action may make this a hard problem to solve.

I have tried coloring on two different structures. This coloring was brought about by the use of sand. On one structure we used a sand that had a reddish-brown tinge—this gave a rich, warm buff color. On another structure we used a sand similar, except that it was lighter, and this gave a color a little darker than cream. Am quite sure that concrete will have many more friends, especially in residence work, when you can produce it in colors that are warmer than its natural one.

Concrete is so lasting that you must be doubly sure to get a pleasing design and, in my opinion, your success lies in handling it in large surfaces. Don't try for too much detail, such as you see in some structures built of cement blocks.

These remarks are based on practical experience, and I trust that they will help to stimulate the discussion of the many interesting features of this broad subject.

ROAD CONSTRUCTION.

Ontario, more so than any of the provinces, has spent money and endeavored to make its road system modern and equal to present day traffic requirements. W. A. McLean, Provincial Engineer of Highways, in carrying out of the plans of the province, has had opportunities of studying and knowing the requirements of roads in a way that makes his report to the government particularly interesting. Writing, as regards road construction, he states:

A perfect roadmaking material, or a single type of road, possessing every desirable quality for service, durability, and cost, has not been found, and from natural reasons, cannot be expected to exist. Roads must be adapted to the traffic they are to carry, and since traffic differs greatly in character, road construction must be varied accordingly. The problem in general is, to use local materials to the best advantage.

Motor traffic is leading to important requirements and modifications, but gravel roads, and broken stone roads substantially as advocated by Tresaguet in France, and Telford and Macadam in England, continue to be the mainstay of road-building.

All roads are important and each deserves a type of construction and system of maintenance in keeping the traffic over it. Some roads have only an occasional vehicle passing over them; others may have an average of 1,500 vehicles of all descriptions. Some carry light single-horse vehicles principally; others have a greater proportion of heavy teaming. The amount of motor traffic varies from roads which have few automobiles to those which have a large number of motors and few horse-drawn vehicles. A gravel road will give good service to a considerable amount of light driving; and an oiled gravel road will serve a very large motor traffic if there is a small proportion of horse-drawn vehicles. A water-bound macadam road is easily maintained under a considerable amount of heavy teaming and light driving, but if even a small proportion of rapid motor traffic is added, the cost of maintenance is much increased; and if motor traffic is of large amount, an asphalt or tar binder becomes necessary, or a durable pavement should be considered. Painting with tar or asphalt will give good service where motor traffic is heavy, with few horse-drawn vehicles; but if proportions of travel are reversed a bituminous paint coat is much less effective. These examples suggest some of the factors entering into the design of a road.

Road Classification.—The roads of Ontario may, for a consideration of construction, be broadly divided into three classes; one grade merging into another, however, at the arbitrary dividing line. It is estimated that in the organized counties of old Ontario there are 50,000 miles of road, and a classification would be approximately as follows:

1. Trunk roads connecting the large towns and cities	5%	or	2,500 miles
2. County or leading market roads	12%	or	6,000 miles
3. (a) Main township roads	50%	or	25,000 miles
(b) Secondary township roads	33%	or	16,500 miles
Total	100%	or	50,000 miles

In the foregoing classification, the roads described as "Trunk Roads" are, with the exception of a few connecting links, among the most important of the county roads, and are heavily travelled for local market purposes, but they carry as well an increasing amount of through inter-urban traffic. The heavy and complex nature of this traffic requires, as a rule, construction of the most durable type varying from a concrete, brick, or other durable pavement to first-class macadam. The classes one and two, including trunk roads and leading market roads, thus include two divisions of what would be the main county roads of the Province. These comprise 17 per cent. or 8,500 miles in all, which if properly selected and constructed should carry 80 per cent. of the traffic of the Province.

The main township roads comprise principally the concession roads on which numerous farms front and which converge into and create the traffic of trunk or county roads. The more important of these should be metalled with gravel or broken stone, if available. Secondary township roads include the little travelled connecting roads which should be graded and given such further treatment as circumstances may permit. The first need for the roads classified as township roads is thorough grading, draining and bridging, and systematic maintenance with the log drag.

Gradients adopted, amount of camber or crown, width and depth of metal, foundation if any, drainage, binding material, and other details, should, as suggested, be largely dictated by the degree of traffic. A good road attracts and creates traffic so that the construction of any one road is very likely to raise it from one class to a higher grade, a matter which should not be lost sight of in planning improvement. Methods of construction should be as simple and direct as proper results will permit. There should, for true economy, be a well adjusted average between maximum service and minimum cost.

Trunk Roads.—Broken stone roads of the best class have been reduced to a few well-defined types, through more than a century of experience in England, France, Germany, and on this continent. The true macadam road has a well-defined and crowned earth sub-grade, over which is spread a uniform coating of finely broken stone of about 2½ inches diameter. The Telford road has a foundation of flat quarry stones, placed by hand, on edge, the angular points being chipped off by hammer and wedged into the interstices; and over all is spread a coating of finely broken stone, in thickness about one-third of the total depth of the stone surface. The earth sub-grade is flat and larger stones are used at the centre of the road, with smaller at the sides, to give the desired camber. The roads built by Tresaguet in France, were substantially the same as the Telford road and are usually included with it. In the former, the sub-grade was cambered, and the foundation stones of uniform depth. A

distinct type of foundation is that developed in Massachusetts in which there is a slightly V-shaped sub-grade with a filling of cobble or field stone, a method which is claimed to give more effectively than other types, a desirable under-drainage.

Experience has shown the superiority of roads with a foundation, such as the Telford type, in reducing the cost of maintenance under heavy traffic. Settlement is more uniform, and defective drainage is less destructive. If the natural sub-soil is strongly supporting, such as a dry, well-cemented gravel, the foundation may be omitted with saving of cost. Whether the Telford or Massachusetts type of foundation be allowed, the local material suitable for either should largely govern.

The width of roadway between gutters or drains, and the width of stone should be guided by the amount and character of traffic, and should ordinarily be less in strictly rural districts, increasing as roads converge into city streets. A minimum width of grade for trunk roads should be 24 feet with metal in the central 12 feet, and earth or gravel shoulders six feet wide on each side. Maintaining shoulders at six feet, and a maximum width of metal at eighteen feet, the maximum width of grade need not exceed thirty feet.

The camber on roads of heavy travel should be the least possible, consistent with good surface drainage, factors to be considered being the quality of road metal, class of binder, and gradient of the road. As is well known, roads with a sharp crown encourage travel in one central line of wheel-tracks, while a flatter surface permits more uniform wear.

A hard rock such as trap, or a bituminous binder, requires less camber than soft material and an inferior binder, while a steep grade requires an increased camber to drain the wheel tracks. Trunk roads of the best class may be given an average crown of one-third or one-half an inch per foot from centre to gutter.

County or Main Market Roads.—Roads of this class cannot as a rule follow closely English, French, German, or other standard, but must be built with a view to the particular needs of this continent, and of the locality. The immediate need is a long mileage, to be built as rapidly as possible, through districts where population is comparatively sparse, often where there may be little or no road-making material, and the available expenditure necessarily restricted by these and other conditions.

European engineers would, undoubtedly, if it were possible to reconstruct many of their roads, lay them with foundations, but the cost is prohibitive. No more is it practicable on this continent to build any but the most heavily travelled roads with expensive foundation. Instead, it is necessary to depend on good drainage, carefully maintained to keep the sub-soil dry and strong enough to sustain the road surface.

Road-beds should have sufficient drainage for the severest test, which in northern countries is that period of thaw in the early spring, lasting usually for two or three weeks; just as bridges have to be strong enough for the maximum load, and with waterway enough for the maximum freshet. If sub-soil drainage is sufficient for the test of spring, no break-up of the road crust need be feared at other seasons.

Old specifications for roads built before the period of railway construction in Ontario, required open drains on each side of the road, with bottom at least two feet below the crown of the road. In most cases the drain was deeper; and hills or spouty places were under-drained with trenches filled with field stone. Such roads have stood the test of time, and may be accepted as the standard of drainage required for the north; except that tile under-drains are taking the place of open ditches where they would otherwise be dangerous, unsightly or difficult to maintain. Drains of porous farm tile keep the sub-soil at its driest and prevent uneven settlement of the road crust into mud which is as destructive to a road when below the surface as when on the surface. Some counties of Ontario are using tile drains the full length of all their roads. Others use them only on wet and spouty hills; on level land which is exceptionally wet and retentive; and where the open drain would otherwise have to be dangerously deep to give sufficient fall and outlet. In the last case, the tile may carry some surface drainage, receiving it in catch-basins.

Closely associated with drainage is the grading of the road. Before a road is surfaced it should be brought to grades that ensure permanence. Hills should be cut down, low places filled, and the earth work brought to a substantial turnpike. The road surface will need renewal, but the grade, if properly made, will outlast even the bond issue. On roads of a secondary class elaborate surveys are unnecessary. A good foreman can obtain easy flowing gradients by grading from point-to-point, and would probably disregard stakes and profiles except in cases of extensive cuts and fills, new locations, tile drains, or doubtful surface drainage, which should always be staked by an engineer.

Roads laid on an earth foundation should be given a higher crown when newly constructed, than is desirable for perfect condition. Settlement will assuredly occur, and unless the road is too high to begin with it will become too flat. A road of a secondary class which in two or three years has settled to the desirable camber will give the greatest degree of durability, with least expense for maintenance. One inch to the foot from centre to gutter or edge of shoulder, for a completed, rolled road, will meet ordinary conditions; with a circular cross-section, the greatest part of the fall is on the earth shoulders.

The cost of a road, unless earthwork and drainage is of an exceptional kind, will depend on the width and depth of broken stone used. Wide flat roads are desirable, but narrow roads with a good camber cost less to build, and much less to maintain, unless a highly organized system of maintenance is created. For this class of road and earth grade twenty-four feet wide, shoulder to shoulder, will meet most conditions; but may be reduced to eighteen or twenty feet for least traffic. With shoulders six feet wide, the stone is put on from eight to twelve feet wide.

The consolidated depth of metal on roads is based on 8 inches for a moderately strong clay or sand sub-soil. This is modified according to the anticipated amount of traffic and quality of stone to resist wear; the maximum concentrated wheel loads; local tire widths and wheel diameters; bond of road metal and consequent distributing effect of the stone crust; the supporting strength of the sub-grade and opportunity for drainage.

Bituminous binders may be justified on heavily travelled suburban or motor roads of this class, but present practice in Canada tends to oiling as a preservative and dust preventive, owing to the less first cost of water bound macadam.

Township Roads.—Reduction of cost to meet township conditions requires that townships have as their ideal, the cheaper class of roads adaptable for main county roads. Grading is cheap, and should be perfected before metal is applied. Neglect to provide easy flowing gradients, and to sufficiently drain and turnpike are mistakes fatal to any road. Minor municipalities can make no mistake in creating the perfect earth road as their ideal base for such metal surfacing as their resources will permit. An earth-grade from eighteen to twenty-four feet shoulder to shoulder should be made, and a single track laid eight feet wide, of gravel or broken stone.

Binder.—The durability of a road is largely dependent on the binder, and the cementing qualities of the stone dust, in producing a waterproof surface,—if tar, asphalt, rocmac or other special binder is not used. Stone screenings are more preferable than sand. Very rarely can gravel or sand, sufficiently clean, coarse and sharp, be found to make a binder equal to limestone screenings. The superior cementing qualities of limestone, make it a better road metal than its degree of toughness would justify. Limestone screenings are also exceedingly useful with water washed gravel, or with broken granite or trap, all of which are deficient in good bonding qualities.

Coursing Stone.—A uniform grade of stone, rather fine, is desirable in finishing the surface of a road, and is necessary where a very hard stone such as trap is employed; but this may be sought at considerably increased cost, and is not always necessary to suitable results. It adds to the cost of a road to spread the stone in several layers. Municipalities using portable crushers particularly, will find a rotary screen with two sizes of mesh very satisfactory. This will produce, (1) "Tailings," or the stone too large to pass through the screen; (2) the middle course, a uniform grade to form the main body of the road; and (3) screenings to bond and finish the surface. The tailings should be spread in the bottom of the road, and covered to the required depth with the uniform grade; and this, after rolling, may be lightly coated with screenings and rolled. If a very tough stone such as trap, the screenings may be such as will pass a one-half inch mesh, or a one inch mesh if limestone; and the uniform grade of stone may be two inches for trap, and two and one-half or three inches for limestone, with the screenings removed. Crushing and handling are cheapened by the system, and for water-bound roads, a smooth surface results.

Trap or other tough rock brought from a distance by rail in preference to the use of soft local material, is justifiable for surfacing heavily travelled main roads; but it is a safe rule, if applied with discretion, that local material if it exists, should be used.

Gravel Roads.—Gravel in general is inferior to broken stone as a road material, but if of a reasonable quality, is suitable for township roads, and for many county roads but, unless of exceptional quality, is deficient for extremely heavy traffic. The rounded pebbles do not take the mechanical clasp that pertains to fragments of broken stone, while the sand which it usually contains is not equal to stone screenings as a binder. It may contain lime or iron, improving its bonding qualities, but as a rule it is not water-proof, and ruts readily in wet weather, especially if it contains sand, clay or loam in excess.

The best quality of gravel is of varying sized grain up to 2 inches in greatest dimension, with only sufficient fine material to fill the voids between pebbles. It should be clean and made up largely of a uniform grade of pebbles—qualities rarely found in natural pit gravel. Gravel pits containing a mass of large stones and boulders should be treated as rock, and put through a crusher. Gravel which is not coarse, but which is "dirty" or contains fine sand, should be screened to remove the excess of sand or clay. A rotary screen may be used, operated by steam power. The gravel can be drawn in wagons to an elevated platform, dumped into a hopper from which it passes through the rotary screen, and from the screen to an elevated bin, from which the screened gravel is again loaded into wagons to be taken to the road. By means of the elevated bins the expense of shovelling into wagons is saved, the time of teams and teamsters is saved, and a well arranged plant will, under favorable circumstances, pay for crushing and screening. This is particularly the case if a pit near the work can be used rather than to team better material a long distance.

Methods.—The methods of construction will largely determine the cost. Machine work is cheaper than manual labor. The cross section adopted should, therefore, permit the maximum amount of machine construction. Particularly for the cheaper class of roads, the grading machine, in treating with old locations, should do most of the earthwork, supplemented with wheeled and drag scrapers. A cheap and good plan is to make the earth sub-grade, shoulder to shoulder between ditches, almost flat, or with a central rise of about three inches for a 24 foot grade. When this is rolled, the stone is spread to the desired width in the centre, then with the grading machine, earth is drawn from the shoulders to support the stone, thus completing the camber. The stone is first rolled dry to level and partly compact the surface, the screenings are then spread, sprinkled and rolled till consolidated. To grade the road and then excavate a central channel to receive the metal is a more expensive method, and is apt, for roads without a foundation, to place the stone too low for good drainage, producing what may be termed a "water-logged" road. Instead of the camber and turnpike being high enough to allow for settlement, it is apt to be made too low and flat.

Rolling.—As distinguished from earlier road-making, modern construction has been largely influenced by machinery, especially grading machines, rock crushers, and road rollers. The smaller municipalities of Canada commonly use graders and crushers, but the purchase of a steam roller is too often delayed. It is to be pointed out that the cost of a roller is by no means an additional expense, since rolling effects economy in several ways. Coarser stone can be used in a road that is rolled, so that the cost of crushing is reduced. With coarser stone, the road is stronger to resist wear, and is more securely bonded than if first rutted and mixed with mud. Less stone is required in a rolled road, as loose stone is largely forced down into the mud before the surface becomes waterproof, or is knocked to the ditches by traffic. Without rolling, roads demand attention for one or two years, to rake the stone to place from time to time; the earth shoulders have to be restored and levelled where cut up and destroyed by traffic, new material has to be added to fill hollows and ruts. By rolling the sub-grade, the wet or weak spots are developed, which can be drained or filled with earth and again rolled to produce a uniform foundation; thereby reducing the stone which the road would otherwise absorb. Long lines of loose stone left for traffic to consolidate are a most objectionable obstruction to travel, and bring road-building into disrepute. On the other hand, a road built with a heavy roller is a complete work, in perfect condition when finished. Rolled roads are a revelation to those who have been accustomed to and who expect only old-time methods and results. For both economy, service, and to popularize the work, rolling should be regarded as essential for every class of gravel and stone roads.

The process of melting abstracts or renders latent a definite quantity of heat, and it is the loss of this heat in the melting of ice that gives it its refrigerating value. This heat, which is used up in the melting of ice, is the latent heat of fusion of ice, and it amounts to 142 heat units per pound of ice. When one pound of ice changes to water the heat that is abstracted is equivalent to what would be required to raise one pound of water 142 degrees Fahrenheit, or required to raise 142 pounds of water one degree Fahrenheit. This quantity of heat is considerable, and accounts for ice being a better cooling agent than ordinary cold water, or even water at 32 degrees Fahrenheit. One pound of ice in melting has, therefore, 142 times the cooling value of one pound of water in passing from 32 degrees to 33 degrees Fahrenheit.

PROPOSED SOUTH SASKATCHEWAN RIVER DIVERSION CANAL.

In the issue of *The Canadian Engineer* of March 6th, 1913, there was an article on the Moose Jaw water supply, by Mr. Gillespie, associate professor of Applied Mechanics, University of Toronto. In this article Mr. Gillespie mentioned that the ultimate source of the water supply at Moose Jaw, if the city increased its population, must be the Saskatchewan River. We publish below a report by the Commissioner of Irrigation, F. M. Peters, on the proposed South Saskatchewan River Diversion Canal. This scheme, if carried through, will be the probable source of water supply for both the city of Regina and Moose Jaw. The estimates of costs given will be of interest to engineers and contractors.

The height of land of Aiktow Creek in township 24:—

High-water level in river	1,632 feet
Height of land, head of Qu'Appelle River	1,720
Difference of elevation	88

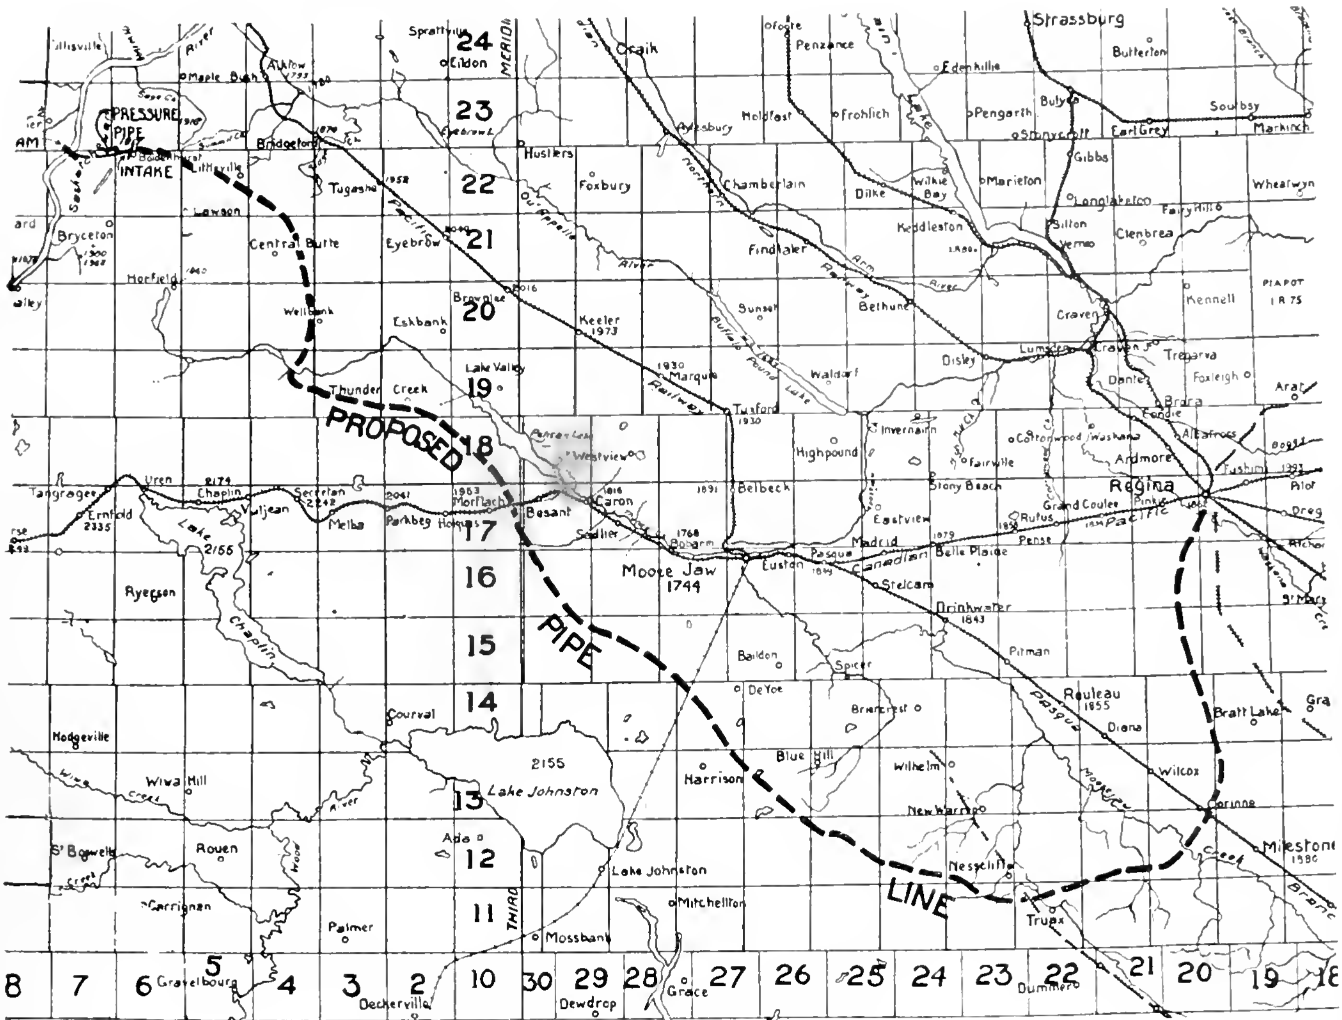
The height of land of Sage Creek in township 23:—

High-water level in river	1,644 feet
Height of land, head of Summit Creek	1,916
Difference of elevation	272

The height of land of Shellstone Creek in township 21:—

High-water level in river	1,672 feet
Height of land, head of Thunder Creek	1,975
Difference of elevation	303

All the elevations given above are to the datum of the Canadian Pacific Railway levels.



Map of Proposed Diversion Canal.

Scale 1″ = 16 miles

A proposition in connection with this scheme, which has been looked upon with some favor is the proposition to pump water out of the South Saskatchewan River over the height of land and deliver it into the head-waters of the Qu'Appelle River. The work was confined entirely to developing the critical elevation along these lines and consisted of running a series of level lines over several heights of land which showed possibilities of feasibility. Mr. Russell was at this work for one month and had the assistance of only one rod man and a team and driver.

The results of all Mr. Russell's work is plainly set forth on the plans and profiles submitted in connection with this report, but for purposes of convenient reference the results may be set forth as follows:—

It should be noted that the pumping of water over the height of land of Shellstone Creek would allow the water to run by gravity down to the city of Moose Jaw and from there down into the Qu'Appelle River.

The project of pumping the water over the Aiktow Creek height of land and allowing it to flow down the Qu'Appelle River would probably be useless, as it would deliver the water into Buffalo Pond Lake at an elevation of 1,627 feet, which is about 117 feet below the elevation of the city of Moose Jaw. Then, allowing a grade in the Qu'Appelle River of two feet per mile, as the crow flies, the elevation of the water in the Qu'Appelle River at a point southeast of Regina (about twenty miles from Buffalo Pond Lake) would be about 1,587 feet or 275 feet below the elevation of the city of Re-

gina. The bed of the Qu'Appelle River is, moreover, of such a character, viz., black swamp earth, that any water turned into it for domestic purposes would be badly polluted.

Mr. Russell also developed a cross-section of the South Saskatchewan River at a point about midway between the mouths of Aiktow and Sage Creeks for the purpose of making a preliminary study of the cost of a dam. This section will give probably as small a cross-sectional area for a dam as any section that can be found on the river in this vicinity. It was also ascertained that the fall of the river water-service in townships 21 to 24, a distance of 31 miles, is 40 feet, or an average fall of 1.3 feet per mile.

Study of Pumping and High Level Gravity Scheme.—Before proceeding with this short study it may be stated that this scheme is a very large one and will be very expensive. It is, therefore, impossible for any person to give an advised judgment on the matter until the topographical features of the country have been fully developed, and the feasibility of dam construction in the South Saskatchewan River fully probed. This study is, therefore, made without any of the requisite information being available, and it must be accepted only as a rough, preliminary study made in an attempt to point out what appears to be the most feasible scheme, together with a rough approximation of the cost.

The purpose to be attained by this scheme is to serve that dry country in what may be termed the Moose Jaw and Regina districts, and the basis of the study is the requirement to deliver a gravity supply as far east as Regina and at the elevation of the rails of the Canadian Pacific Railway in that city. The quantity of water to be diverted has been taken as stated in the application made by the government of the province of Saskatchewan, which is about 200 cubic feet per second.

It is submitted, as a matter of opinion only, that the only feasible scheme is to place a dam in the South Saskatchewan River and develop there enough water-power to pump the required quantity of water to a sufficient height on the side-hill of the river from whence it can be run by gravity to meet the requirements of the situation, which is to deliver a gravity supply at the elevation of the Canadian Pacific Railway at Regina. The supply must be delivered during both summer and winter for domestic purposes, and, with this end in view, the available water-power in the river has been based on the figures of minimum winter-flow.

The cost of a gravity line has been estimated by assuming that the water would be carried in a circular reinforced concrete pipe. It has been assumed that the demand for water will be equal from the intake to the delivery at Regina, where a flow of 50 cubic feet per second has been allowed, and the total length of 170 miles of pipe line has, therefore, been divided into four sections having, from the intake on, carrying capacities, respectively, of 200, 150, 100 and 50 cubic feet per second. The excavation cost has been based on a level section cut for the trench sufficient to bury and cover the pipe everywhere with six feet of earth. In computing the cost of the dam the section used is that one taken in township 24 between Aiktow and Sage Creeks, but, in order to suit the assumed scheme, the dam must be placed somewhere in townships 22 or 23. One fact alone which is liable to make the estimate of the cost of the dam seriously in error is that the bottom of the South Saskatchewan River is known to be most treacherous for the foundations of any structure, and no definite information whatsoever has been gained on this point.

The small-scale map accompanying this report shows the position of the dam and the location of the proposed pipe line, while the calculations following hereafter have been made in such a way that they may be read through understandingly by any person who has followed this preliminary discussion. The unit prices assumed in the estimate are understood to include the cost of many small details and incidentals which have not been calculated. For example, it will not be possible to obtain the minimum excavation section for the pipe line throughout, which will make the quantity of excavation much higher than that calculated.

In conclusion attention may again be drawn to the fact that this study is only a rough approximation and that nothing further can be attempted until the many controlling elements of the scheme have been fully developed by the carrying out of the proper surveys and also river borings to develop the possibilities of a dam foundation.

DETAILED DISCUSSION.

To find the height of dam necessary.

Argument.

H_R = head required for turbines in river to pump Q_C into pipe

Q_R = available L. W. flow in river assumed = 3,000 c.f.s.

C_1 = efficiency of turbines and direct connected centrifugal pumps assumed = 52%.

C_2 = loss due to friction in pipes from pump to delivery assumed = 10%.

H_C = height of lift to pipe.

Q_C = quantity required in pipe assumed = 200 c.f.s.

Formula $H_R \times Q_R \times C_1 \times (1\text{-}C)_2 = H_C \times Q_C$

Study.

Regina elevation	1,862 feet.
Length of canal	170 miles.
Grade of canal = 1 in 10,000 or 0.528 ft. per mile.	
Head required for canal = intake to Regina..	89 feet.
Intake of canal (Boldenhurst Street) elevation	1,951 "
L. W. natural at dam (about)	1,653 "
Head required at dam (H_R)	37 "
Top of dam	1,690 "
Lift required—top of dam to canal intake	261 "

To find the cost of the dam.—The dam section developed on the river gives a cross-sectional area from the river-bottom to the crest of the dam, 37 feet above the lower pool, of 118,000 square feet. A preliminary study of the cost of the dam was made by Mr. W. G. Bligh, M.I.C.E., based on a concrete dam of the arched buttress type. The dam-section used was a very economical one, but of a somewhat bold design, and a rough estimate based on it gave a cost of $600,000. Owing to the uncertainty of the foundations and the many contingencies that might arise it would not be safe to estimate the cost of the dam at any less than $1,000,000.

To find the cost of turbines and pumps.

Theoretic H.P. required = .001892 Q.H. = 12,600.

Allow cost at $15 per H.P. = $189,000.

To find the cost of pressure pipes from pumps at dam to intake of concrete pipe line.

Q = 200 cu. ft. per second.

V = 3 s.f.

A = 67 sq. ft.

R = 4.6 feet (one large pipe).

Area plates required, including laps, 29 sq. ft. per ft. run.

Half-inch wrt. iron plates, weight per foot run, 580 lbs.

Cost, at 6 cts. per lb., about $35 per foot run.

Cost for 1 mile, $184,800.

To find the cost of concrete pipe.

Argument.

1.30 bbl. cement at $3.00	$ 3.90
0.44 cu. yd. sand at $1.25	0.55
1 cu. yd. stone at $1.50	1.50
Total cost ingredients 1 cu. yd. concrete	$ 5.95
Cement and stone	$ 5.95
55 lbs. steel at 3 cents	1.65
Forms, labor, and materials	1.85
Mixing and placing concrete, labor	0.85
Placing steel at 0.2 cents	0.11
Bending steel at 0.06 cents	0.03
Moving forms	0.30
Cost in place, 1 cu. yd. concrete	$10.74
Superintendence, plans, contingencies, etc.	1.26
Total cost in place, 1 cu. yd. concrete	12.00

To find the cost of excavation.

Argument.

Excavation, cu. yd.	$0.30
Back fill, cu. yd.	0.10
Cost per cu. yd.	$0.40
Superintendence, plans, contingencies, etc.	0.05
Total cost, 1 cu. yd. excavation	$0.45

To find cost of pipe line.—The grade throughout has been figured at 1 in 10,000 and the discharge of the pipe has been calculated by the Chezy-Kutter formula, using 'N' = .012.

Study.

Section No. 1, length 42 miles, capacity 200 c.f.s.

243,714 cu. yds. concrete at $12.00 .... $ 2,924,568
Cost per mile, $69,632.
1,576,935 cu. yds. excavation at 45 cents........ 709,621
Cost per mile, $18,834.

Total cost .... $ 3,715,586

Total cost per mile, $88,466.

Section No. 2, length 42 miles, capacity 150 c.f.s.

222,192 cu. yds. concrete at $12 .... $ 2,666,304
Cost per mile, $63,481.
1,576,935 cu. yds. excavation at 45 cents 709,621
Cost per mile, $16,895.75.

Total cost .... $ 3,375,925

Total cost per mile, $80,379

152,633 cu. yds. concrete at 12 .... $ 1,831,596
Cost per mile, $42,595.
1,354,915 cu. yds. excavation at 45 cents 609,712

Cost per mile, $14,179.34.

Total cost .... $ 2,441,308

Total cost per mile, $56,774.34.

Section No. 4, length 43 miles, capacity 50 c.f.s.

127,912 cu. yds. concrete at $12 .... $ 1,534,944
Cost per mile, $35,696.37.
1,164,715 cu. yds. excavation at 45 cents 524,122
Cost per mile, $12,206.70.

Total cost .... $ 2,059,066

Total cost per mile, $47,885.25.

Total cost of pipe line laid, 170 miles $11,591,885

Summary of estimate of cost.

Cost of dam	$ 1,000,000
Cost of turbines and pumps	189,000
Cost of pressure pipes	184,800
Cost of concrete pipe line	11,591,885
	$12,965,685
Total cost, about	$13,000,000

FIRING OF STACKED COAL.

Every now and then some firm which has a quantity of coal on hand finds itself bothered from its coal pile having caught on fire. The question has been discussed lately in a paper read before the Manchester District Institution of Gas Engineers. Mr. Kendrick, who owns gas works of his own, relating his experience with them, stated that at Stretford they have had three serious fires in four years, and many cases of overheating. No. 1 store of coal held 1,800 tons, and was an old retort house partly roofed, with and partly without louvres. No. 2 store holds 1,400 tons and has no louvre. No. 3 holds 800 tons, and has a two-span roof of corrugated iron. In the first two, coal is delivered by conveyors. In No. 3 it is hand-stacked, 14 ft. high. In the other stores it is piled in pyramids 24 and 20 ft. high, the top of the cones being 8 ft. across. No. 1 shed had given most trouble. The finest slack is usually sent direct to the retorts, but much fine stuff still gets into the store and fills the middle part of the piles, and to this dust and small coal the fire trouble is due.

As a result of what was observed, after each boat had been discharged, the fine dust was dug out and spread over the heap, and pipes were put in at intervals to enable the interior of the pile to be watched. Three years of immunity led to laxity, and the small stuff had not been fully dug out, and a fourth fire occurred. It was again the small coal which heated, but was not the immediate cause. Some old screened coal was buried under the new coal, and the store was filled, in about six weeks, to its utmost capacity. On emptying the shed, the rough coal under the slack was quite carbonized and fire was creeping under the slack. Apparently air had reached the new coal through the old tongue of open rough coal. The temperature in the tubes rose slowly to 90 deg., then quickly to 110 deg., with a quick jump to 300 deg., and it required a week to reach the fire, which had then spread considerably. As this coal was stored in the hot month of May, 1912, and was stacked quickly and was dustier than usual, these causes appear to have been active in producing fires.

The colliery agents attribute the numerous fires of that year to the fact that after the strike, coal was much crushed at the face, and was very small, and it was not clean, being hurried away quickly for use, and more probably fresher coal than usual was stacked. Freshly-wrought coal is more prone to heat, especially if fine.

Coal as received is warmer than the atmosphere, as much as 2 deg. to 12 deg. in summer, and 4 deg. to 20 deg. in winter. Since a pit may have a temperature of 90 deg., coal must start from the pit fairly warm, and if stacked too soon, too high, or in too large mass, it is prone to heat. Also, coal mined first after the strike would be damper than usual, and dampness seems to engender fire.

Coals absorb from one to three times their volume of oxygen, and this produces heat, and if it can occur in a thick mass the heat accumulates. Stacking in cone shape from a conveyor causes the fines to accumulate at the apex, and

these are apt to fire. This system of storage is thus to be regarded with suspicion. Coal owners suggest 11 to 15 ft. as the height of coal stacks, or a mean of 13 ft. Gas works practice is to stack 10 to 30 ft. Since coal under cover cools less slowly, it should be stored in less depths than when out of doors, whereas the reverse is the usual practice. The question of ventilation is a disputed one. Some men say ventilate freely and carry off the heat. Others say keep out all hot air and no heat can be generated. If this is so it would be quite safe to store in closed bunkers, exhausting the air at the top and admitting CO_2 at the base to fill the voids between the coal. In practice it appears that coal will be reached by air enough to make it become hot. Therefore, supply ample air to carry off the heat, for the oxidation will be less if the coal is cold. Yet in mines ample ventilation to remove gas has caused heating in the gob, and the checking of the air current has stopped the heating.

If a heap fires, very much water is needed to quench it, for water sets up air currents to fan the fires. At Stretford they treat affected coal with strong ammoniacal liquor and only put water on unaffected coal. The summing up is that coal from different seams should not be mixed, nor should coal of different classes.

Fine slacks should not be stacked at all, nor damp coal under cover. Large heaps are the more dangerous. Lumps, nuts and fines should be well mixed in stacking. Limit heights to 20 ft. in the open, and 16 ft. under cover. Avoid external sources of heat, leaking roofs, &c. Keep temperature records of coal as received and in stock, and if the heat rises to 90 deg. or 100 deg., remove the top layers and watch carefully. Do not disturb a fired heap by pushing in bars. Do not apply water to a fire, but ammoniacal liquor. Remove and use heated coal promptly.

From remarks made during the discussion, it would seem that if coal is screened and stacked it does not become hot. This indicates the smalls as the cause of trouble. But it also indicates the need for good air circulation, for it is the fines that prevent this. It seems impracticable, as a rule, to gain safety by excluding all air, as that would undoubtedly prevent fire, for to produce fire there must be oxygen. The question is, can coal absorb oxygen, as oxygen which shall only begin to work when the coal is stacked? With present-day large stacks of coal, the subject becomes important.

MINERAL PRODUCTION BY PROVINCES.

The subdivision of the mineral production in 1911 and 1912 by provinces for Canada was approximately as follows:

Province.	1911. Value of Production.	1911. Per cent. of Total.	1912. Value of Production.	1912. Per cent. of Total.
Nova Scotia	$15,409,397	14.93	$18,843,324	14.15
New Brunswick	612,830	0.59	806,584	0.61
Quebec	9,304,717	9.01	11,675,682	8.77
Ontario	42,796,162	41.46	51,023,134	38.33
Manitoba	1,791,772	1.74	2,314,922	1.74
Saskatchewan	636,706	0.62	909,934	0.68
Alberta	6,662,673	6.46	12,110,960	9.10
British Columbia	21,299,305	20.63	29,555,323	22.20
North West Territories.	4,707,432	4.56	5,887,626	4.42
Dominion	103,220,994	100.00	133,127,489	100.00

CONSTANCY OF VOLUME ACCELERATED TESTS IN PORTLAND CEMENT.

At the meeting of the International Association for Testing Materials, amongst the discussions that arose the questions regarding constancy of volume accelerated tests in Portland cement were eagerly discussed. Professor Max Gary, in a paper discussing accelerated tests in Germany, states the accelerated test for volume constancy was discussed as far back as the Zurich meeting of the International Congress for Testing Materials. At that time, Dr. P. Prüssing exhibited samples containing 50 per cent. of highly expansive constituents, but so finely ground that they slaked readily, without expansion, on being stirred up with a large volume of water, though when mixed with only a little water, for the production of cement ware, considerable expansion occurred. Thus, even at that time, proof existed that a test in which the cement is mixed with much water does not always cast suspicion on such dangerous cements as those in question; and a desire arose for the introduction of some method of testing with specimens made up with only a little water (earth-damp or dry).

Experiments with various testing methods failed at that time to lead to the desired result; and in course of time other proposals were made in succession for the rapid testing of cement in order to detect any tendency to expansion. Among these may be mentioned: The Drying test at 100 degrees C. (Darrprobe), the Heintzel ball test (calcination test), the Michaelis boiling test, the Von Tetmajer ball test, the Maclay hot water test and the Prüssing pressed block test.

All these tests met with opposition, and in 1891 the Association of German Portland Cement Manufacturers gave expression to the following opinions:—

(1) The test for standard constancy of volume in Portland cement is sufficiently decisive and perfectly adequate for practical purpose, if performed with care.

(2) The accelerated tests, hitherto published, for ascertaining inconstancy of volume in Portland cement are not adapted to enable the consumer to form a reliable judgment on the cement, it being found that some Portland cements which fail to pass the accelerated tests, prove thoroughly constant in volume when in use.

On the other hand, there were loud expressions of opinion, particularly by Von Tetmajer, Bauschinger, Dr. Michaelis and C. Prüssing, to the effect that the standard tests were insufficient for judging cement, especially when the cement was intended to be exposed to the air during setting in pactical use. His opposition to its views induced the association to appoint a committee entrusted with the solution of the following question:—

Does the standard test for constancy of volume in Portland cement enable an accurate judgment to be formed on the behavior of a cement in use, or is this object attained in a more reliable manner by any of the proposed (accelerated) tests?

Without delay, the committee began operations in collaboration with the Royal Mechanico-Technical Laboratory at Charlottenburg.[1] The laboratory procured ten cements which, according to the users, had behaved satisfactorily in practice, though failing to pass the boiling test. All the cements were tested by the laboratory and by the members of the committee separately, as regarded their general properties, changes of volume in the Bauschinger tester, tensile strength and behavior under the above-mentioned tests for constancy of volume. Moreover, reliefs and conduit covers were made from the cements at the cement works for the purpose of being exposed to the air, subject to all changes in the weather during setting.

It is impossible here to go into the details of the experiments, but it must be specially mentioned that none of the so-called "accelerated" testing methods tried (drying test at 100 deg., Heintzel ball test, Von Tetmajer ball test, Maclay hot water test and Prüssing pressed-block test) appeared calculated to enable a rapid and reliable judgment to be formed in all cases as to the suitability of a cement for practical use.

The experiments showed that all ten cements which passed the standard test also exhibited constancy of volume (in the practical sense) when used for making test pieces and cement ware. The practical utility of the cements was also demonstrated by the increased tensile strength of the test pieces when allowed to harden in water and in the air.

The assumption that the standard test for judging a cement is inadequate, especially when the cement is intended, in practice, to harden in the air, failed, therefore, to obtain any confirmation through the experiments of the committee. That body, however, expressed its willingness to carry out additional experiments, and publicity requested the adherents of the accelerated methods of testing to place at its disposal sufficient quantities of such cements as passed the standard test, but failed to pass the accelerated tests and were found to expand in practice. Cements of this kind were to be forwarded to the Charlottenburg laboratory. In spite of the long term appointed, no response has been received on this matter by the laboratory, and no experimental material for testing in the above-mentioned manner has been furnished.

This might have been considered as settling the matter; but the laboratory has gone further, and has continued for years to keep under observation the cements (and the articles made therefrom) characterized as highly suspicious from the results of the accelerated tests without, however, finding any alteration in the result.

Accordingly, the assumption that the so-called accelerated tests for constancy of volume enable, in general, a more accurate judgment to be formed on the suitability of a cement than is done by the standard test should be dismissed as erroneous. Following on the experiments, however, the laboratory requested a large number of officials to keep under observation the constructional works carried out by them with cements which, according to the accelerated tests, ought to be of a suspicious character; and the results of such observations have been compared with the results of the accelerated tests on constancy of volume. This comparison established in an unimpeachable manner that numerous cements of different origin and methods of preparation, which had partially or entirely failed to pass the accelerated tests for constancy of volume, were found to have fulfilled their purpose completely, irrespective of the conditions of the mixtures, during an observation period of 34 to 18 months, without giving rise to the smallest objection in connection with their constancy of volume.

Furthermore, it has been established by a circular inquiry among more than 200 users of cement that the dubious value of the darrprobe and boiling test in particular has already been recognized in practice, and that there is no longer any need for such tests. In numerous instances it was found that testing in the standard manner sufficed completely to reveal the inferiority of a badly prepared cement. Six cements, which, on the basis of the boiling test and drying test at 100 deg. C. ought to have ranked as quite useless, have been employed, officially, for a variety of building purposes, e.g., in building a fire station; for concrete and masonry in harbor work; in abutments and circumvalliation work in a fortress; in building a high-level water tank; in the piers of a large railway bridge; for concrete floors and ceilings, etc. In all cases the work has remained under observation for several years, but in no case, however, has the work given rise to complaint on the score of changes in volume, or in any other respect, although the constancy of volume of all these cements, as determined by the darrprobe, calcination test and boiling test, was open to the gravest suspicion, and although remarkable phenomena were exhibited at the end of one and two years by the test blocks in air and water. No injurious effect could be observed in practice—in a very thick concrete wall—even in the case of a cement which was completely disintegrated by the boiling test, and showed reticulated and edge cracks at the end of two years in a test block immersed in water. The thoroughness of these observations and determinations is probably unsurpassed.

After the publication of these results the question of accelerated tests for constancy of volume slumbered for some years, so far as Germany was concerned, until Le Chatelier proposed to fill the cement paste into split brass rings fitted with needles and test the expansion by measuring the distance between the needle points after treatment in hot water. Hence the Le Chatelier test is an improved form of boiling test.

Quite recently Dr. G. Hentschel has proposed a modified boiling test for cement. Instead of performing the boiling test after the block has been hardened for 24 hours, he proposes a preliminary treatment to accelerate the hardening before applying the test. The block is to be left for 15 to 20 minutes on a highly absorbent gypsum plate, and then be heated, on an iron plate, over a naked flame until no more water vapor is given off. After cooling, it is immersed for ten minutes in water at room temperature, and is then exposed to the air for three hours, being finally boiled. It should be remarked that one cannot expect this test to furnish any essentially different information from that given by the old darrprobe and boiling test; and it will prove unreliable and misleading for the same reasons as the older tests.

Greater attention was bestowed on the Le Chatelier test, mainly because, in contrast to the other methods, it furnished values which were regarded as mutually comparable. The British Standard Committee took up the Le Chatelier test; and from England this test was laid before the International Association and caused to be accepted by the Copenhagen Congress, 1909, as a commendable accelerated test for constancy of volume, although a number of expert members protested against this decision. The protest was entered in the minutes of proceedings, and is now brought to remembrance again.

In justification of this protest, reference was made at Copenhagen to the aforesaid unfavorable experiences with the boiling test. It must be reiterated that the Le Chatelier test is a boiling test, and therefore must also be judged, like the old boiling test, on the basis of the comprehensive experiments already referred to. Moreover, it is necessary to point out the opinion in which this test is held even in England.

At a meeting of the Concrete Institute in 1910, Mr. Butler read a paper on tests for constancy of volume, which paper was followed by an extremely animated discussion. The reader of the paper supplemented a historical review of the development of the existing tests by an exposition of the theoretical advantages of the Le Chatelier test; but on the basis of many thousand experiments with the Le Chatelier needle came to the conclusion that, owing to the often contradictory results in cases where the cements would have to be condemned on account of failure to pass the Le Chatelier test, the results must not be interpreted too strictly. He also demonstrated that divergent results could be obtained in different localities, and that the results also differed even

when the tests were performed at one and the same place and under perfectly identical conditions. It is highly interesting and characteristic of the lack of practical value of the test that the results of Butler's experiments entirely coincide with the experiments (to be mentioned later) carried out by the Association of German Portland Cement Manufacturers. Butler found:

In the first place, that with three operators working in the same place and with the same molds, the results of the tests showed extreme divergences. One operator found considerable expansion of the cement, whilst the other two found much less expansion. According to the result of the one test, the cement would have to be discarded as not being constant in volume; whereas, on the basis of the results obtained by the other two, under precisely equal conditions, the cement was not open to objection.

In the second place, Butler found that an extraordinary influence on the results was exerted by the use of different kinds of needles, whether brass or copper, old or new.

Thirdly, he found that on many occasions the test pieces gave higher expansion values after the cement had been exposed to the air for 24 hours or 6 days than when the same cement was used in the original conditions. He points out that, in the English method, the expansion during the first 24 hours—which in many cases is far greater than the subsequent expansion—is entirely neglected by the boiling test, and that leaving the cement 24 hours to harden before boiling is quite an arbitrary procedure.

At the conclusion of the paper, the author said that, whatever good reasons might exist, either in favor of or against accelerated tests for constancy of volume, he could vouch, from his personal experience, for the fact that not 90 per cent. of the Portland cement made in England or elsewhere less than 20 years ago would have been able to pass the boiling test under the conditions laid down. If this test were indeed an accurate one for constancy of volume, the evident conclusion would be that 90 per cent. of the total cement used 20 years ago was not constant in volume. This would be a somewhat surprising assumption when it was remembered that hundreds of thousands of tons had been used for important structures in different parts of the world; and in view of the excellent present condition of these structures, the assumption could not be seriously brought forward.

This paper was read at a meeting under the chairmanship of Mr. Blount, the advocate of the Le Chatelier test at Copenhagen. Mr. Blount's criticism of the paper was that he did not agree with Mr. Butler. This terse but unfortunately, merely ex parte opinion was, however, not shared by a large number of well known English cement manufacturers, who expressed their agreement with Mr. Butler. Among others, objections were raised against the Le Chatelier test by Messrs. Bamber, Cooper, Tristam, Watson and Roberts.

So far as the Association of German Portland Cement Manufacutrers is concerned, the Le Chatelier test was first tried, in 1909, by a special committee, under the chairmanship of Director Schindler. It appears from the comprehensive report that, as was found by Butler, there was no harmony between the results obtained at different testing stations. The experiments were continued, on a larger scale, in 1910 with six cements. The results were most contradictory, one and the same cement giving expansions varying between 0 and 10.7 mm. of needle divergence at different stations. Schindler's report contains all the individual values and careful drawings of the results at ten testing stations.

At the Royal Laboratory for Testing Materials, experiments were carried out in 1911 with six Le Chatelier needles, of different kinds of brass and copper, and the experiments, like those of Butler, show that the results of the Le Chatelier test vary according to the kind of material and method of making the needles.

Consequently, the apparatus is, in itself, uncertain and unreliable.

Finally, under the chairmanship of Dr. Strebel, committee No. V. of the German Association for Testing Materials, made a thorough investigation of the Le Chatelier test, and Dr. Strebel presented his report to the twelfth general meeting of that association held in Düsseldorf on October 7, 1911.

The experiments led to the following conclusions:

(1) It has been found that the Le Chatelier test characterized as constant in volume a cement which exhibited a decided tendency to expansion in cold water. Even if the cement in question be one of abnormal composition, it was, nevertheless, bought in the open market; and consequently the buyer of such cement would, if he relied on the results of the Le Chatelier test, have incurred risks by using the cement in practice.

(2.) It was also found that the results obtained in testing one and the same cement in different testing stations varied in such a manner that in quite a number of instances a cement would pass the test in some stations but not in others. The risks arising from such unreliability on the part of an extremely important test do not need to be enlarged upon. The matter is rendered more serious by the fact that the tests in question were performed by skilled operators exclusively, and in strict accordance with the prescribed conditions.

Owing to the coincidence of these results with all those obtained in the previous experiments, the committee—comprising not only manufacturers, but also a large number of the most prominent cement experts in Germany—decided to invite the German association to adopt the following resolutions:—

(1.) The German Association for Testing Materials rejects the Le Chatelier test as an accelerated test for constancy of volume.

(2.) The Association requests the International Association for Testing Materials to set aside the resolutions adopted at Copenhagen with reference to the Le Chatelier test.

At Copenhagen it was evident that the German cement industry would have to fight shy of the introduction of the Le Chatelier test, and that the resistance offered to this test by the German members was based on that circumstance. On the other hand, it should be mentioned that already in 1909 experiments with the Le Chatelier test were carried out in the laboratory of the Association of German Portland Cement Manufacturers, as reported by Dr. Framm in 1910. According to the English regulations, the expansion of the test pieces (cement not exposed to air) should not exceed 10 mm. after six hours' boiling. This condition was fulfilled by 83 samples out of 88 German commercial cements, originating from 88 different makers, 79 of the samples giving an expansion of less than 5 mm. and only 4 samples one, between 5 and 10 mm. The mean expansion of the entire set of samples, including those which failed to pass the test, was only 3.5 mm. This shows that if the Le Chatelier test gave reliable results, the Germans need not fear its introduction. It is, however, rejected because the result of the test is uncertain and bears no relation to the other properties of the cement.

Basing on the foregoing unassailable facts, I arrive at the following conclusions:—

The decision of the Copenhagen Congess to commend the Le Chatelier test as accelerated test for constancy of volume is not borne out by the facts of the case. The Le Chatelier test is misleading and should therefore be discarded.

CONTENTS OF THIS ISSUE.

THE SMOKE PROBLEM.

A most difficult problem to satisfactorily solve in cities is the pollution by smoke of the atmosphere. It may be merely an unpleasant and jarring note on the beauty of the scenery to the suburban residents, but it has an added and more serious meaning to those living in the smoke area, and that usually means a majority of the citizens.

A certain amount of dust and impurities from the streets will always of necessity be found in the city atmosphere. The presence of such is a menace to health, and every added pollution by smoke only further endangers the public's well-being. All these points are well known, and pressure has in a way been brought to bear on the scientist to in some way abate the nuisance.

Legislation, it would seem, is the only way to cure the evil, and that involves the interruption and interfering with of long-used rights. Without knowledge and accurate data of the exact amount of smoke pollution in our towns, legislation on the subject is extremely difficult, and there must ultimately devolve on engineering shoulders the task of gathering these data.

Any attempt so far at the abating of the smoke nuisance or of obtaining information on the subject seems to have been local and confined to independent municipal effort. There is no organized effort in Canada to systematize and collect smoke information. Vancouver, for instance, in a recent report to the City Council, by a Smoke and Sawdust Abatement Society, recommended as follows:—

That the offer of a public service corporation to supply the city electric light, heat and power for consumers by developing electricity and steam heat from lumber refuse be accepted. The franchise to the company was to be for thirty years. Besides relieving the city of part of its smoke, consumers were to be supplied with energy at the following rates: electricity at eight cents per kilowatt hour, and subsequently seven and six cents; heat at $1.00 per 1,000 pounds of steam pressure development. The company was to pay the city one per cent. of gross earnings the first ten years, two per cent. gross the next five years, and two and a half the succeeding five years. The company was also to start operations within fifteen months and to expend $50,000. Now the above contract is very interesting, and might help Vancouver in its smoke trouble, but it is questionable whether a remedy on such lines would be practicable in other cities. Vancouver in being a city of many lumber mills has possibly sufficient waste product available for fuel to make such an attempt possible. The majority of Canadian cities and towns have not that resource. It is legislation that will help all municipalities that must be hoped for as the desired goal.

In England a committee of scientists have been appointed who have formulated a plan of investigation that ought to lead to more definite information of the pollution of atmosphere than we have yet had. All the principal local authorities of the United Kingdom are to be communicated with in the hope that they will co-operate in an organized attempt to collect reliable data as to the degree of the pollution of the atmosphere in different places. No co-ordinated effort has ever previously been made to estimate the amount of suspended matter in the air. A standardized method of examination of the atmosphere is to be adopted, and the result ought to be the collecting of much useful information. The standardized method of investigation is to be (a) a form of enlarged rain gauge, with catch area of four square feet, and a large bottle is provided to collect rain, soot, or other

deposits falling. The bottle is removed periodically and the amount of solids estimated. This is a method for use over long periods.

(b) A measured volume of air drawn through filter paper is the method for measurements of solids from day to day or hour to hour.

One cannot help feeling that such a systematized course of investigation should be inaugurated in Canada as well as Great Britain. It is only through reliable knowledge of conditions gained by such means that we can ever hope to be able to effectively handle the problem. It is only when the exact amount of the pollution of atmosphere we are undergoing is known; when we have some idea based on facts of the amount of injury to health dwellers in the cities are risking. It is only then that corrective legislation will be properly balanced.

Tampering with rights of usage and time by regulations which might seriously affect vested capital is too serious a problem to be encouraged without full knowledge of the conditions to be remedied. We would probably either allow more pollution than is good for us, or go to the other extreme and be unnecessarily harsh in our regulations if we approached the subject in any other manner. Active steps should be taken in Canada to gather information and data on smoke pollution similar to those being carried on in the United Kingdom. It is a step towards better laws that we should all hope to see.

SPONTANEOUS COMBUSTION.

The liability of coal in bulk to take fire from spontaneous combustion is generally known among the engineering profession. The chemistry and cause of the action may not be so familiar to many of our readers. Possibilities of fire due to chemical action taking place between the air and the coal is well understood by chemical engineers and by those accustomed to handling or using coal in bulk. It is a question which has been well treated in an article on another page of this issue by the owner of gas works who had suffered considerably in a business way due to fires brought on by spontaneous combustion. The subject, moreover, has peculiar significance just at present, due to the recent catastrophe at Baltimore, whereby a ship that was loading dynamite was blown up and forty or fifty people killed. While there is no official version of the cause of the explosion, it was apparently due indirectly to fire generated by spontaneous combustion in the coal bins. Accounts that come of the length of time between the discovery of the fire until the actual explosion took place lead one to believe that the dynamite was not the original source of trouble. Moreover, fire otherwise located than in the bottom of the coal bunkers, would probably be quickly observed and extinguished before it was too late to prevent the explosion of dynamite. Everything considered, it seems reasonable to blame the coal bunkers and spontaneous combustion as the cause of the catastrophe. One can be glad that reason and charity go together to support the belief that unforeseen and unguarded chemical actions were the cause of the accident rather than pure human carelessness.

The whole subject of the explosion can be understood by a study of the previously mentioned article. Coal, it appears, absorbs from one to three times its volume of oxygen. This produces heat, and, occurring in a thick mass, the heat accumulates, and ignition is the result. It seems a disputed point, according to Mr. Kendrick, whether free ventilation should be aimed at to prevent combustion, or whether the method whereby no warm air is to be allowed near the coal, and so no heat generated, should be adopted. The latter method being true, it is quite safe to store coal in closed bunkers, exhaust the air at the top and fill the voids between the coal from below with carbon dioxide.

Coal of large size with few fines in it will ordinarily not take fire. Nevertheless, Mr. Kendrick claims that in coal mines ample ventilation has sometimes caused heating in the gob (waste fillings in mine), and choking off the air current has stopped the heating. Water is not very satisfactory for quenching coal piles that are on fire if in small quantities, and may, if so used, only increase the combustion and heat. One can understand, therefore, how, in a ship loaded with dynamite, fire, once well started in a coal bunker, might be inextinguishable when discovered before the serious danger of the fire had extended to the dynamite.

Knowledge has forearmed man sufficiently against spontaneous combustion, so that, ordinarily speaking, he should be able to guard himself against serious danger from it. With proper attention during loading, or with a proper system of inspection afterwards, a ship carrying dynamite could be made safe from such an occurrence as spontaneous combustion. It is unfortunate that it is usually tramp steamers that carry the most dangerous cargoes around. The officers and crew may not be in a position to either know how or to be able to enforce intelligent and scientific orders and inspection for the prevention of accidents. It will be interesting to note what steps, if any, will be taken to prevent a re-occurrence of such an accident as that brought about by spontaneous combustion occurring in coal bins of a ship loaded with dynamite.

EDITORIAL COMMENT.

The arrival of Easter brings to end one of the mildest winters Ontario has ever experienced. The corollary follows that it has been an exceptionally fine winter for those trying to carry on outdoor work or building construction. Winters of such a mild nature as that just past are always welcome to engineers. The cold is a serious drawback to all forms of construction, and the arrival of spring, we hope, heralds the approach of a summer of unexampled activity in all engineering lines. Railroads under construction and extension; the Welland and Georgian Bay Canal schemes; harbors in almost all our Canadian cities under plans for improvements and increased shipping accommodation. All these items and many smaller ones go to make up a gigantic programme to prepare for and consider in an engineering way.

LARGE WIRE ROPE.

A large cable which has been used for 18 months in lowering 50-ton trucks down an incline into a mine in Cuba has been tested at Lehigh University, Pa. A portion of the worn cable withstood a test of 300 tons. The cable itself is believed to be unique in wire rope manufacture; it consists of six strands, each having 19 wires, placed around a wire rope centre, and the centre is composed of six strands of 19 wires each twisted around a hemp rope. The length of the cable was 7,810 feet, and it weighed over 125,000 lbs.

ELECTRIC RAILWAY STATISTICS.

The growth of electric railways throughout Canada is well shown in the following statistics, published by the Department of Railways and Canals, Ottawa. Two companies failed to make their annual report to the Department for 1912, i.e., the Montreal Tramways and the St. John Electric, consequently, in the statistics given for 1912 it has been necessary, as regards the above-mentioned companies, to assume the figures from their 1911 reports as applicable to the following year.

Operations for the year show growth in all departments and a general extension of the electric railway interests.

Mileage.—Track mileage for the past four years is shown in the following table:—

Length of Tracks.	1910. Miles	1911. Miles	1912. Miles
Length of first main track	1,049.07	1,223.73	1,308.17
Length of second main track....	242.39	259.74	294.50
Total length of main track.....	1,291.46	1,483.47	1,602.67
Length of sidings and turnouts..	91.39	103.54	120.84
Total, computed as single track.	1,382.85	1,587.01	1,723.51

It will be observed from the foregoing that there was an increase of 84.44 in first track mileage, and of 34.76 in second track mileage—a total for 1912 of 119.20. The increase in sidings and turnouts amounted to 17.30 miles. The actual gain for the year in trackage of all sorts was 136.50 miles.

For purposes of comparison, the following table shows first track mileage since 1910:—

1910	1,047.07
1911	1,223.73
1912	1,308.17

Improperly included double track and sidings.

Capital Liability.—There was an increase for 1912 of $11,309,599 in capital liability, which brought the total up to $122,841,946.

The facts with respect to capital liability since 1910 are as follows:—

	1910.	1911.	1912.
Stocks	$ 58,653,826	$ 62,251,203	$ 70,829,118
Funded debt	43,391,153	49,281,144	52,012,828
Total	$102,044,979	$111,532,347	$122,841,946

The foregoing statement does not include cash subsidies to the amount of $493,346 received from governments and municipalities.

Earnings and Operating Expenses.—Gross earnings from operation in 1912 totalled $23,499,250.31—an increase of $3,142,298.61 as compared with 1911.

Following were the sources and items of gross earnings for the year:—

Car earnings—	
Passengers	$22,007,750.15
Freight	1,025,371.93
Mail and express	78,818.66
Other car earnings	67,022.30
Total car earnings	$23,178,693.04
Miscellaneous earnings—	
Advertising	$ 71,226.65
Rent of land and buildings	21,228.39
Rent of tracks	13,836.70
Rent of equipment	56,239.74
Sale of power	37,083.98
Other miscellaneous earnings	120,671.81
Total miscellaneous earnings	$ 320,287.27
Gross earnings from operation	$23,499,250.31

A comparative statement of car earnings for the past three years shows the following result:—

Gross car earnings.	1910. $	1911. $	1912. $
Passengers	16,125,944.72	19,130,370.22	22,007,750.15
Freight	575,536.84	744,179.11	1,025,371.93
Mails and express	68,604.11	88,233.13	78,818.66
Other earnings ..	51,241.07	100,930.12	67,022.30
Total	16,821,376.74	20,063,718.58	23,499,250.31

An outstanding feature in the foregoing statement is the steady rise of earnings from freight. In 1904 there had been an increase to $182,143, and in 1906 to $288,105. In 1912 the earnings from freight reached $1,025,372—showing the extent to which that aspect of public service had grown in twelve years.

Table 4 will afford details with respect to earnings.

Following is the balance sheet for 1912:—

Earnings and income—		
Gross earnings from operation		$23,499,250.31
Operating expenses		14,266,674.63
Net earnings		$ 9,232,575.68
Miscellaneous income		1,617,017.78
Gross income		$10,849,593.46
Deductions from income—		
Taxes	$1,581,802.81	
Interest—funded debt	1,570,202.02	
Interest—floating debt	193,068.26	
Other deductions	188,582.57	
	$3,533,655.66	
Undistributed	1,378,906.56	4,912,562.22
Total net income		$ 5,937,562.24

The undistributed amount given above relates to the British Columbia Electric Railway Company, which operates, in addition to an electric railway, a lighting and power plant. A separation is not made in the balance sheet of that company of items which would establish the real net income of the electric railway interest by itself.

If the undistributed income had been added to net income, as was done in preceding years, the amount of the latter for 1912 would have been $7,315,937.80, as compared with $6,592,535.30 in 1911. It would not, however, be strictly correct to do that, since it represents a total from which proper deductions had not been made. The definitely known net income is the sum given in the balance sheet, although it is probably below the actual amount.

The amount of dividends and bonuses paid during the year was $4,229,005.75. These payments were equal to 5.9 per cent. of the total stock issue.

Following is a comparison of deductions from income for the past three years:—

	1910.	1911.	1912.
Taxes	$1,311,953.65	$1,437,045.07	$1,581,802.81
Int. on funded debt	1,449,152.48	1,622,780.11	1,570,202.02
Int. on floating debt	156,546.16	157,843.38	193,068.26
Other deductions ..	36,106.97	155,149.97	188,582.57
Total	$2,953,759.26	$3,352,818.53	$3,533,655.66

Operating expenses for the year totalled $14,266,674.63 as against $12,096,134.22 in 1911.

The ratio of operating expenses to gross earnings was 60.71 per cent., as compared with 59.42 in the preceding year.

Following was the distribution of operating expenses in 1912, with a comparison for 1911:—

Operating expenses.	1911.	1912.
Maintenance of way and structures	$ 920,874.93	$ 1,228,972.10
Maintenance of equipment	1,758,289.10	1,859,939.21
Operations of power plant	2,001,543.00	2,535,573.10
Operation of cars	5,768,085.10	6,770,560.47
General	1,610,098.62	1,871,626.75
Total	$12,096,134.22	$14,266,674.63

Following is a comparative statement of the items comprising operating expenses for the past three years:—

	1910.	1911.	1912.
Maintenance of way and structures—			
Track and roadway	$ 590,363.28	$ 693,498.75	$ 857,796.61
Electric line	152,874.47	163,108.91	227,562.04
Build'gs and fixtures	54,657.28	64,697.11	143,613.40
Maintenance of equipment—			
Steam plant	38,305.93	46,504.31	50,137.15
Electric plant	45,148.10	65,145.02	87,570.70
Cars	692,276.38	790,609.02	916,755.20
Electric equipment of cars	481,301.83	546,276.52	630,521.52
Miscellaneous equipment	58,815.63	99,831.25	86,053.80
Miscellaneous shop expenses	202,591.58	192,608.03	67,493.89
Transportation—Operation of power plant—			
Power plant wages	178,389.69	207,118.54	205,858.34
Fuel for power	271,410.36	332,584.89	315,019.83
Water for power	21,398.33	21,947.47	13,979.30
Lubricants and waste for power plant	10,538.93	10,702.75	11,006.39
Miscellaneous supplies and expenses	17,916.34	29,120.20	22,051.25
Hired power	1,087,273.72	1,390,810.05	1,901,757.49
Transportation—Operation of cars—			
Superintendence	192,567.60	250,459.73	319,399.37
Wages of conductors	1,749,916.70	2,070,624.01	2,423,060.35
Wages of motormen	1,697,096.68	2,024,115.38	2,371,529.39
Wages, miscellaneous car service	152,950.35	294,498.67	339,771.00
Wages, car house employees	393,998.76	287,441.56	400,967.61
Car service supplies	94,486.16	151,489.64	161,895.17
Miscellaneous car service expenses	183,526.94	306,931.96	304,898.48
Hired equipment	42,136.56	55,278.55	73,876.17
Cleaning and sanding track	65,200.30	80,302.13	86,514.84
Removal of snow and ice	238,881.58	246,043.47	285,662.53
General—			
Salaries of general officers	236,575.70	279,819.40	327,451.09
Salaries of clerks	202,712.98	250,902.23	274,832.47
Print'g and stationery	33,634.34	44,284.36	53,073.13
Miscellaneous office expenses	44,336.11	34,944.72	54,474.14
Stable expenses	30,817.44	33,047.06	47,031.82
Store expenses	33,841.10	37,876.19	43,908.89
Advertising and attractions	47,411.04	49,948.03	30,706.15
Miscellaneous general expenses	133,752.32	165,707.31	154,432.11
Damages	342,120.26	357,270.67	536,273.01
Legal expenses	8,784.32	9,107.93	4,406.14
Miscellaneous legal expenses	54,336.64	63,311.08	53,089.47
Rent of land and buildings	20,936.74	28,310.05	29,651.68
Rent of track and terminals	98,753.70	110,846.74	90,751.33
Insurance	118,930.80	144,713.85	148,309.34

Public Service.—During the year 488,865,682 passengers were carried, exclusive of 125,453,320 transfers, showing an increase of 62,568,890 as compared with 1911.

The carrying of these passengers involved a car mileage of 80,402,089. Freight, mail, and express business had a car mileage of 1,667,975. There was an increase of 8,867,961 in passenger car mileage, and 583,297 in freight car mileage, over 1911.

The following statement shows the growth of passenger traffic since 1910:—

1910	360,964,876
1911	426,296,792
1912	488,865,682

The number of tons of freight hauled was 1,435,525, as compared with 1,228,362 in 1911. Owing to an erroneous return in 1911 by one of the Ontario companies, the figures published in that year in relation to freight tonnage were considerably exaggerated.

Equipment.—The following statement will show the number and classes of cars in service in 1912, with the figures for the two preceding years:—

Classes of cars, etc.	1910.	1911.	1912.
Passenger, closed	1,795	1,985	2,049
Passenger, open	994	990	866
Passenger, combination	337	455	574
Freight	282	357	483
Mail, express and baggage	25	33	33
Combination, passenger and freight	-	5	7
Work	[illegible]	108	[illegible]
Snow ploughs	[illegible]	60	57
Sweepers	97	106	112
Miscellaneous	103	225	194
Total	3,789	4,325	4,478

Employees.—The number of employees in the service of electric railways on June 30, 1912, was 14,760, as compared with 13,671 in 1911.

The total of salaries and wages for the year was $9,261,370.26, as against $8,559,215.04 in 1911.

Salaries and wages in 1912 were equal to 64.91 per cent. of the operating expenses, as compared with 70.76 in the preceding year.

The following comparative table will show the number and classes of employees in 1912 and 1911:—

Employees.	1911.	1912.
General administration—		
General officers	163	159
General office clerks	694	744
Maintenance—		
Superintendents	89	90
Other employees	4,546	4,922
Transportation—		
Superintendents	111	118
Other employees	8,157	8,727
Total	13,671	14,760

WESTERN CANADA POWER COMPANY'S HYDRO-ELECTRIC PLANT AT STAVE FALLS, B.C.

One of the most important hydraulic installations Messrs. Escher Wyss and Co., of Zurich, Switzerland, have installed in Canada is the Stave Falls plant of the Western Canada

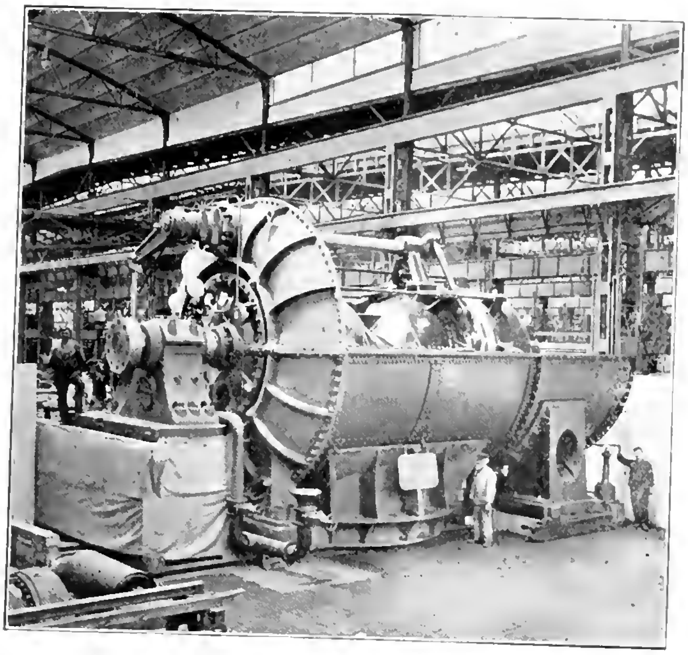

Fig. 1.—13,000 H.P. Turbine, rear view.

Power Company. The power station is located about 35 miles from Vancouver at the Stave River Falls and utilizes a fall of about 100 feet.

By building two dams at the upper side of Stave Falls a large reservoir has been created reaching to the upper end

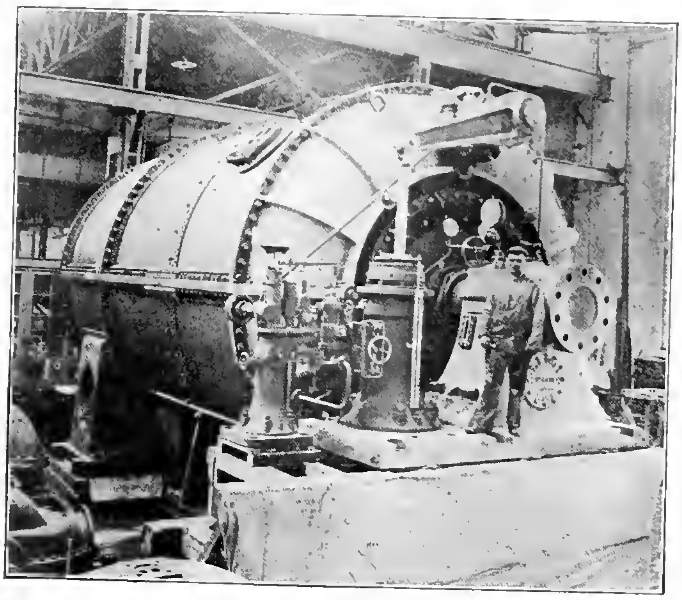

Fig. 2.—13,000 H.P. Turbine, Front View.

of Stave Lake, a distance of 16 miles, with an area of 18 square miles; this storage capacity, together with the flow of the river, is sufficient for 28,000 h.p. continuously, and for a peak load of 50,000 h.p.

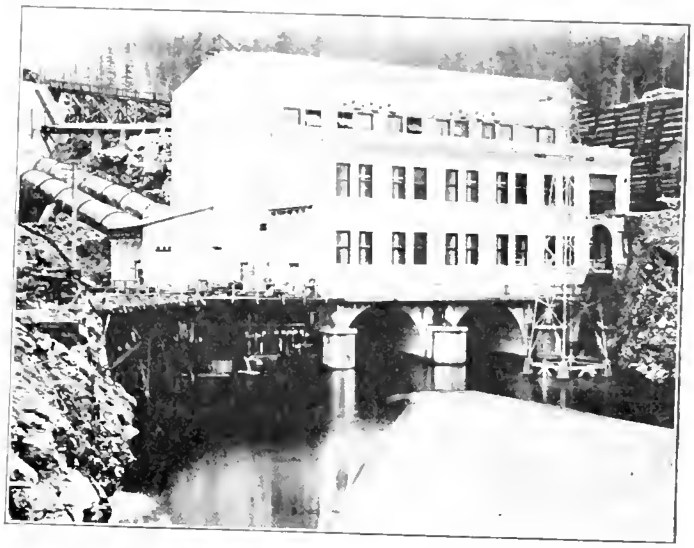
By raising the dams additional storage can be obtained and the plant be brought up to the full capacity of 100,000 h.p.

At present 26,000 h.p. are developed and two units of 13,000 h.p. are installed. The water is taken from a forebay by means of two penstocks, each having 14'6" diameter and a total length of 150 ft. The penstocks for the two exciter turbines are 4 ft. in diameter.

The design of the main turbines is shown on figures 1 and 2. These turbines are of the Francis type with horizontal shaft, double wheels and central discharge, delivering through a short draught tube formed in concrete to the tail-race. The level of the water in the tail-race is kept constant at elevation 110 ft. The level of the water in the forebay varies from a minimum of 210 ft. to a maximum of 230 ft., the head varying thus from 100 ft. to 120 ft. The average head is 110 ft. Under this head the turbines have to give a maximum power of 13,000 h.p. on the shaft when running at a speed of 225 r.p.m.

Regarding the design, the following remarks may be of interest:—

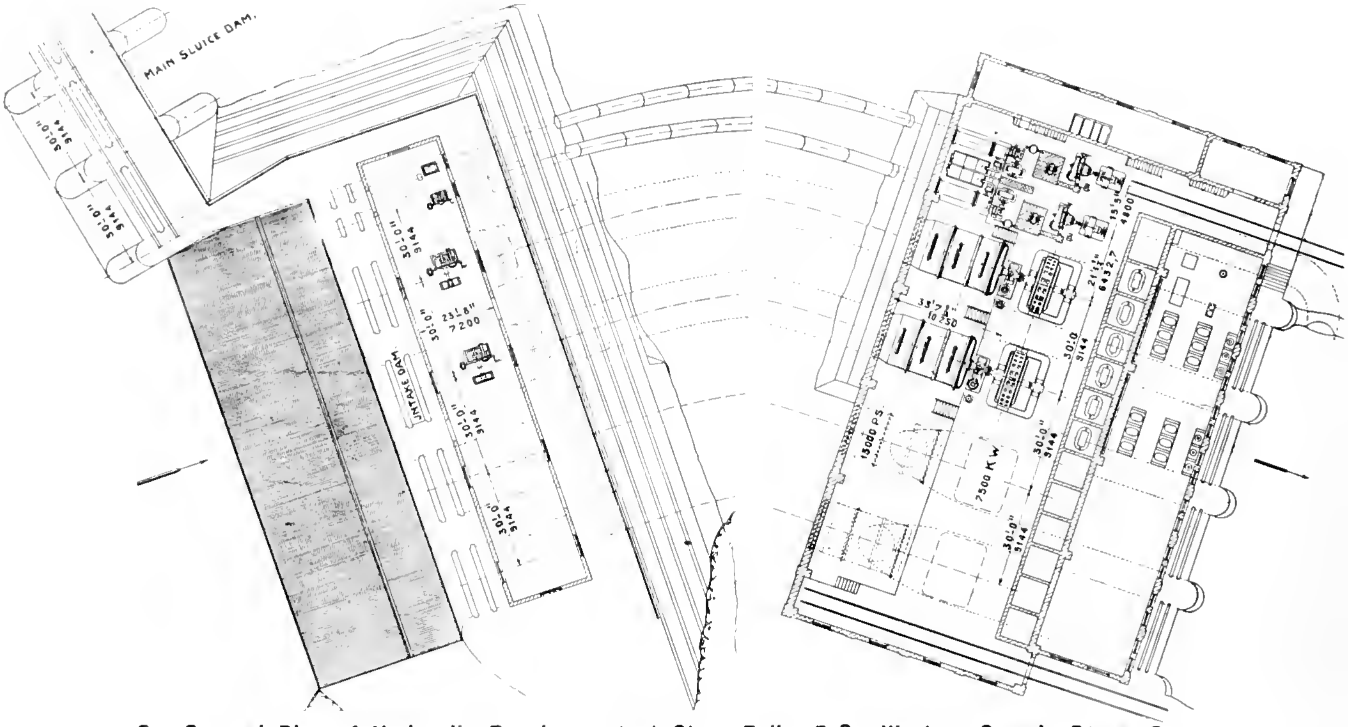
The wheel casing is made of steel plates with heavy steel angles; it is divided horizontally so that the upper part can be removed for easy access to the turbine. Heavy angle irons stiffen the casing so that it cannot spring out of shape



Power House, Stave Falls, B.C., Western Canada Power Company.

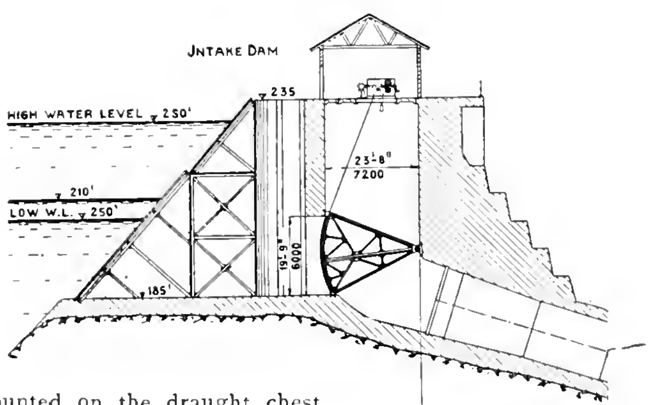
when taken apart. To connect the casing to the penstock a taper piece is inserted. The main cover is made of cast steel, strong enough to withstand a pressure amounting to twice that due to the static head. The bearings are of very large dimensions, the generator bearing being arranged in such a way that it can be sunk by taking out an intermediate piece under the pedestal so as to allow for dismantling of the shaft. The outer bearing is protected by a housing, into which access is allowed by means of a steel tube. It will be noted that a considerable distance between the two bearings is allowed, but Escher Wyss and Company consider this arrangement better than to have a third bearing inside the draught chest which is not free to inspection and thus means a weak point in the design. The shaft is made in one piece and of sufficient thickness at the centre to revolve without the support of a middle bearing and without undue deflection. The half couplings are forged on both the generator and the turbine shaft. A strong cast iron foundation frame supports rigidly the draught chest and cover. No steel girders are used as foundation, but the whole is grouted in concrete. The runners are made entirely in cast steel. Considerable difficulty was experienced by the steel foundries to cast these runners, but in the end faultless casts were obtain-

ed and the high efficiency these runners have shown gives high credit to the designers. The guide vanes are of cast steel, and all steel bolts are provided with suffing boxes and bronze bushings so as to guarantee smooth working and possibility of dismantling. The regulating rings have been



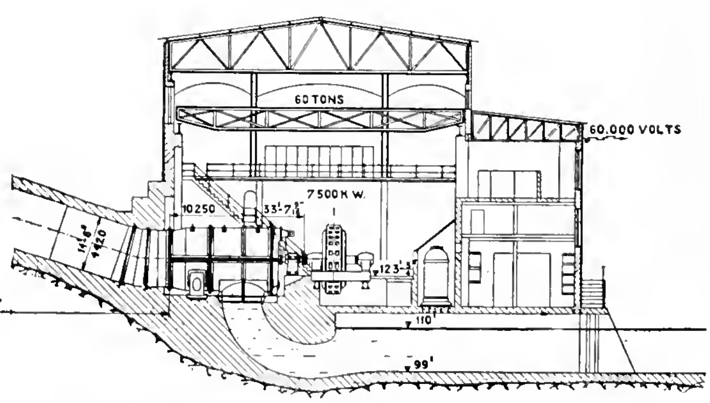
C.—General Plan of Hydraulic Development at Stave Falls, B.C., Western Canada Power Co.

given a profile of maximum possible resistance and stiffness, which in this case is of great importance, as the diameter of the ring is 9 ft. These rings, as well as all covers, stuffing boxes, etc., are split horizontally. A regulating shaft of 10 inches diameter, supported by white metal bearings



mounted on the draught chest, operates the regulating rings. The shaft, on the other hand, is operated direct from the servo-motor working under oil pressure supplied by an oil pumping plant. The speed governor is driven by belt from the main shaft. The servo-motor consists of a differential cylinder, which, by means of pressure oil from the air vessel produces the power required for moving the governor gearing of the turbine. Pipes from wither side of the piston connect to the controlling valve mounted on the casing. This valve contains several chambers communicating with the respective servo-motor chambers and oil tank. The spring pendulum contains fly-weights loaded by compressed springs. The larger springs are supported by the pendulum casing, the smaller ones by the movable discs, which latter are adjustable in the radial direction, whereby the compression of the springs and therewith the speed of the pendulum is varied. The speed can be regulated by turning a handwheel on the governor or from the switchboard by means of a small electric motor mounted on the pendulum. The pendulum shaft is driven by worm wheels from the horizontal shaft, which latter is driven by belt from the turbine shaft. The movement of the fly weights in the pendulum is transmitted to the regulating lever. A relay consisting of a dash pot serves as second compensation device. Governing by hand can be effected by means of a hand governing valve, which admits pressure to one or the other side of the servo-motor piston. The oil pressure necessary for the governors of both turbines is supplied by an independent plant.

POWER HOUSE.



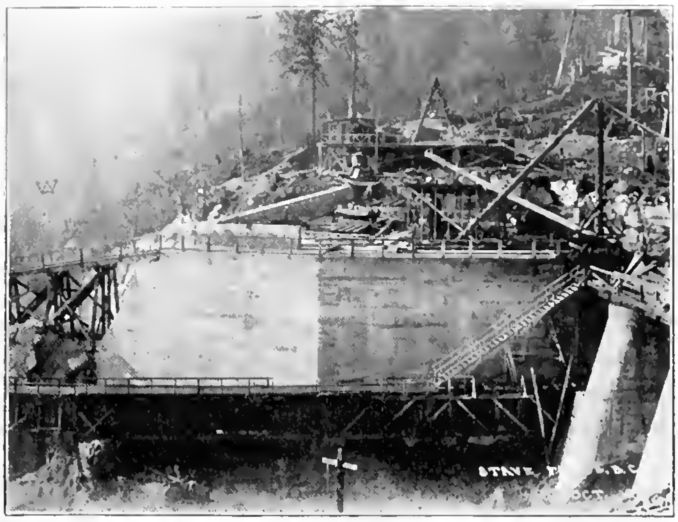
D.—Elevation and General Plan of Hydraulic Development at Stave Falls, B.C., Western Canada Power Co.

It consists of two complete units, each unit being capable of supplying under normal conditions the necessary pressure oil for the governors of the two main and the two ex-

citer turbines. Each unit consists of an impulse wheel direct connected to a three cylinder single acting oil pressure pump which draws the oil from an oil tank and forces it into a strong air chamber, whence the governors of the turbines are fed. After leaving the governors the oil is flowing back to the oil tank passing an oil filter. The impulse wheels receive water through pipes connected to the exciter pipeline.

The exciter turbines are single wheel Francis turbines with horizontal shaft in spiral casing, each designed for 500 b.h.p. when running at a speed of 500 r.p.m. They are fitted with Escher Wyss and Co.'s patent universal oil pressure governor of the standard type, and are direct connected to two exciters.

The electrical equipment of the power station, which was supplied by the Canadian General Electric Co., consists of 2 generators having a nominal capacity of 7,500 k.w. each and 2 exciters rated at 250 k.w. each. They are capable of giving a continuous overload of 25 per cent. and are producing continuously 9,375 k.w. at a power factor of 85 per cent. The normal voltage is 4,000, periodicity 60 cycles. They are guaranteed to run at a speed of 75 per cent. in excess of the normal.



Intake of Stave Falls Plant, Western Canada Power Co.

The transmission lines from the power house to the receiving station is designed for 60,000 volts.

The weight of the water-wheels is 165 tons per piece, while the generators weigh 160 tons each.

The plant was first started up in December, 1911, and, according to a statement made by the Western Canada Power Co., not the slightest difficulty was experienced, neither on the hydraulic nor the electrical machinery. It has during the fourteen months run given full satisfaction in every respect.

Modern research has brought to our industries, at a marvellous rate, not only new compounds but even new elements. Prof. H. T. Kalmus, of Toronto, calls attention to the fact that of the fifty metallic elements now known only seven were in commercial use 2,000 years ago and until 100 years ago the rate of addition was less than one metal for each two centuries. Within the last twenty-five years about fourteen metals have been added to commercial use—an addition at more than one hundred fold the previous rate.

IRRIGATION SURVEYS AND WATER POWERS.

The magnitude of the work which the Commissioner of Irrigation for the Dominion Government of the Provinces of Alberta and Saskatchewan is doing may not be altogether realized by readers who have not come in direct touch with this department. The work is carried on under the Director of Forestry, and the annual publication of the department contains many interesting details submitted by the Commissioner, F. H. Peters, A.M. Can. Soc. C.E., D.L.S. Those portions of his report which are likely to be of interest to our readers are condensed in the following paragraphs:—

The irrigation office may be said to be the guardian of the water resources of the provinces of Alberta and Saskatchewan, and this naturally carries with it great responsibilities. Much of the work done by this office must necessarily be for the benefit of future generations, and this, unfortunately, does not tend to make the work popular with the people of to-day. This is especially true of the work of stream measurement that is being carried on, and, because there is plenty of water for everybody to-day, even the most interested parties, who are themselves licensed by the government to use water, do not appreciate the work and do not realize that a perfect system of stream measurement means a perfect safeguard to their water-rights in the future, and that every dollar spent to-day in prosecuting this work means many dollars saved in the future in the prevention of litigation that must arise if the load that is placed on every stream is not carefully guarded to-day. Our neighbors to the south have learned this lesson by costly and bitter experience, and we may, if we will, profit by their experience and avoid the mistakes which they made during the earlier days of irrigation development.

General Information Regarding Irrigation in Alberta and Saskatchewan.—The irrigation office has jurisdiction over all water-grants made in the provinces of Alberta and Saskatchewan (except grants for water-power purposes, which are handled by a separate branch), and it can be easily understood that the patrolling of this vast area requires a large staff and a sound organization.

The remarks here following relate almost entirely to the work of irrigation inspections. The work done by this office naturally divides itself into two separate branches: irrigation inspections, together with reservoir site surveys, etc., and the stream measurement work. The two are closely associated and must go hand-in-hand, but are submitted separately in order to keep down the bulk of each volume, and also because the report of progress of stream measurements is nearly all composed of tables of gauge-heights and discharges, and is more fittingly published in a separate report for convenience of reference; a brief, general report on stream measurements is, however, appended hereto.

In order to give an idea of the extent to which irrigation is now being carried on in the western provinces the following brief summary is given:—

The total amount of water granted by the Dominion Government in the two provinces is 23,865 cubic feet per second. Of this total amount 23,536 c.f.s. have been granted for purposes of irrigation, leaving 329 cubic feet per second divided up between the other three classifications; that is, domestic, industrial and other purposes.

In Alberta the total amount of water granted for irrigation purposes is 23,114 c.f.s., or enough to irrigate 3,467,100 acres of land, according to the authorized duty of water, which is 2.023 acre-feet per acre.

Of this quantity four large companies have 22,500 c.f.s., leaving 614 c.f.s. divided up among 320 individual users; excluding from these twenty-four applicants who each have an average grant of about eight c.f.s., we get figures for the average individual water-user, viz.: 414 c.f.s., divided

up between 296 individual users, which gives each one 1.40 cubic feet per second, or enough to irrigate 210 acres of land.

Of the four large companies mentioned above, the following facts may be stated: The Canadian Pacific Railway Irrigation Company has been granted from Bow River, near Calgary, 3,000 c.f.s. at low-water stages, 13,000 c.f.s. at high-water stages, and 15,000 c.f.s. at flood stages. It has approximately one million acres of irrigable land, and already has issued over 1,500 agreements to furnish water to settlers within this tract.

The Alberta Railway and Irrigation Company has been granted from Belly River 500 c.f.s. at all stages of flow, from Milk River 500 c.f.s. at low-water and 1,500 c.f.s. at high-water and flood stages, and from St. Mary River 500 c.f.s. at low-water and 2,000 c.f.s. at high-water and flood stages. It should be noted, however, that the total amount of the grants from Milk River and St. Mary River have been somewhat modified under the terms of the International Waterways Treaty recently made between Canada and the United States. This company has already issued water agreements to over 800 water-users.

The Southern Alberta Land Company has been granted from Bow River 2,000 c.f.s. at high-water and flood stages, and from the South Saskatchewan River 1,000 cubic feet per second at all stages. This company has developed a very large reservoir for the storage of flood waters, in order to utilize its high-water and flood license from Bow River. The works are not yet completed, and, therefore, the company has not as yet entered into any agreement to supply water to actual users. The company controls about 400,000 acres, about half of which is irrigable.

The Alberta Land Company, operating as a subsidiary company to the last-named company, and diverting water through its works, has a grant of 500 c.f.s. from the Bow River at high-water and flood stages. The works of this company are not yet completed.

In the province of Saskatchewan irrigation has not been undertaken to nearly the same extent as in the province of Alberta, and it has no large irrigation companies. There has been granted to date in Saskatchewan, for irrigation purposes, 423 cubic feet of water per second, and this quantity is divided among 241 individual users. This gives each one an acre of 1.75 cubic feet per second, or enough to irrigate 262 acres.

Licenses are granted by the Dominion Government, under the administration of the Minister of the Interior, for the use of water, under the following classification:—

1. Domestic uses.
2. Industrial uses.
3. Irrigation purposes.
4. Other purposes.

The procedure followed in granting water-rights is, briefly, as follows:—

Any applicant for a water-right must first submit a memorial setting forth the purposes for which the water is required, and, accompanying this, must be general and detail plans showing where, and how, and for what purpose, he intends to use the water and what works he intends to construct or install. The next step is an inspection of the scheme by one of the government engineers, who reports upon the feasibility of the scheme, the question of water-supply and the character of the works to be constructed. The proposed scheme is then advertised in a local paper for six weeks, in order to give the local public notice of what is proposed and what water-supply and lands will be affected. Any protests which may be made against the proposed scheme are carefully investigated. Authorization is then issued for the construction of the necessary works, and a limit of time is placed within which the construction must be completed. The Department's engineers inspect all schemes periodically during construction, and, finally, after the works have been satisfactorily completed and inspected, the water license is granted.

The work of inspection is divided into two districts, within which the bulk of the work lies, viz.: the Maple Creek district and the Calgary district; the other schemes, which are widely scattered, are inspected by so-called special inspectors.

The Maple Creek district is under the especial charge of a division engineer, who has under his control two assistant engineers, each with a field party working under his direction. The Calgary district is patrolled by one district engineer with a small party.

Determination of the Low, High and Flood Discharge of Streams.—In order that the following may be intelligible it is necessary to explain the procedure in granting water-rights against any stream or other source of supply. The procedure is to consider that every stream has three separate stages of flow; that is to say, low-water stage, high-water stage and flood stage, and each water-license is issued against a specified stage of the stream flow.

In order that, under average conditions, there may always be enough water in the stream to fulfil the obligations of all the licenses issued, it is clear that the records of this office must show definitely the quantity of water in the stream, under such average conditions, at the three stages above mentioned. It is also clear that it is a most difficult matter to determine accurately the flow of the stream at the three respective stages: in fact, these figures can only be determined with even a fair degree of accuracy after a long series of stream measurements has been carried on on each stream. It is at this point that the work of stream measurements is indivisible from the work of irrigation inspections.

At the present time the quantities for all the streams, shown against the stages of low, high and flood discharge, are most inaccurate, as they, indeed, must be, because at the time when they were computed several years ago practically no continued series of stream measurements had been made.

During the present winter the matter of determining these quantities with some degree of accuracy is being actively taken up. The Department now has fairly complete records of stream-flow on several streams from the year 1908 to the year 1911, inclusive, and on most of the important streams used for irrigation purposes the records of stream measurement date back to 1909. The procedure being adopted is as follows: A separate sheet is being prepared for each stream, and on this is being plotted as a profile the mean monthly discharges for all the years during which records have been obtained. The profile for each year is plotted with a different colored ink, so that the different years can be readily distinguished. After a careful study of each sheet two horizontal lines are drawn across the profiles showing the three stages of flow as arbitrarily determined from the study. The horizontal lines are drawn only in pencil, so that at some future time, when more records of stream-flow are available, they may be shifted if necessary to more accurate positions as shown by the increased length of the period over which the stream measurements have been gained.

This arbitrary determination of the stage of the streams is a most important matter, as, if these determinations are in error, the streams will either be over-recorded or under-recorded. In the first case, the existing rights of the first license will be jeopardized, and, in the second case, applications will be refused when sufficient water is really available and might be put to beneficial use for irrigation or other purposes.

The rivers must be regulated for all beneficial purposes in order to develop their maximum potentiality; so should the regulation of all the beneficial purposes be carried out

by one department so that in studying any scheme of conservation every beneficial use may be given due consideration. Forestry, irrigation and drainage are at present in one branch of this department, under the Director of Forestry, but the investigation and regulation of power production is a separate branch. It is most important that this work should be included in the work of the irrigation office, or at least placed under the direction of the same head, the Director of Forestry. The water-power branch has its headquarters at Ottawa, far removed from the scene of its work, and it has no organization in the West with which to carry out the necessary investigation. The irrigation office, on the other hand, has its headquarters at Calgary, and has a well-organized establishment and a staff of engineers familiar with western conditions. In concluding this topic the case of the Bow River is most illustrative. The government anticipates reservoiring the waters of this river, and in doing so it must consider the claims of irrigation, and also of power production. The claims of these two industries are antagonistic, in that irrigation requires the stored waters for use in the summer and power production requires the stored waters for use in the winter. The two demands have to be adjusted and balanced, and it would be waste of space to further explain that this question can far better be studied and adjusted within the confines of one branch of the department than by two separate branches, neither of them responsible to the other.

The people in the United States have, after long years of bitter experience, come to the concrulsion that these matters are indivisible. Cannot we save all the inevitable blunders and heart-burnings of the future by profiting by their experiences and having this matter adjusted at once?

GOOD ROADS IN ONTARIO.

Last month the Ontario Good Roads Association held its annual meeting in Toronto. On that occasion W. A. McLean, Chief Engineer of Highways for Ontario, gave an address before the Association, an abstract of which we are now pleased to present to our readers.

The roadways constructed under the county road plan last year, aggregating 240 miles, and if placed in a continuous line, would extend from the city of Toronto to Ottawa, a fairly good stretch of highway. If we keep improving in the future as in the past, the prospects are very favorable for a good system of highways throughout Ontario. During the past few years, the cost of highway construction in Ontario has greatly increased. Highway construction is not made up of the cost of material in the pit, or stone in the quarries, nor by the cost of machinery, but rather by the cost of grading and drainage, of operating machinery, of getting material out of the pit and out of the quarry, crushing and preparing it for the roads and putting it in place. That means that the principal cost of road construction goes into wages of men and teams. Ten years ago, the cost of labor was $1.25 for men, and teams could be had for $3.50 per day. I have seen, this year, instances of men being paid $3 a day, and teams $6 a day, with a fair average over Ontario of $2.50 per day for men and $4.50 and $5 for teams, which means that the cost of road construction is practically twice as much to-day as it was ten years ago.

To meet the situation, we shall have to dispense, as far as possible, with horses and manual labor, and turn our attention to road building through the use of machinery. But, to build roads with economy by the use of machinery, we must keep the machinery steadily employed. We must stop the annual patching of roads by men and teams, and expand the county road plan; not to build roads in short, scattered sections, but rather in long stretches.

Road Drainage.—Last season one of the striking features of the year was the heavy rainfall, and from all sides we heard that the roads were badly worn. Where our road went to pieces, under the influence of last season's heavy rainfall, it means largely, a lack of drainage; that sufficient precaution had not been taken to put a proper crown on the road, open ditches, and put in culverts where they ought to be. We have got to drain in Ontario, not for the ordinary summer weather, but for the heavy rainfalls which come periodically; and for the Spring time.

We have a standard type of roadway in Ontario. The width between the shoulders is 24 ft., the crown depending upon the width of stone, and varying from half-an-inch to an inch per foot between the shoulder and the top of the road. Below the shoulders, there should be 18 inches or two feet of drainage. The stone in the centre should depend upon the traffic over the road, ranging from 8 to 16 feet wide.

Everybody wants good roads, but few want to pay for them. They do not want to pay for them with half the zeal with which they ask for them. It is extremely important in entering upon any scheme of construction to have an equitable system of distributing the cost. The people of this country will not object to pay a reasonable price for good roads if the cost is equitably placed upon those who should pay for them. My experience is that, while the people at the commencement are often opposed to good roads, when they begin to see results, they say "That is the road we want, and will pay what it should cost."

The increase in the price of property along highways which have been recently constructed, indicates the real service good roads are to a country. We talk about the service good roads do socially, commercially and otherwise; but getting to practical dollars and cents, we find that property along a good road is increased to the extent of $500 to $2,000 for each one hundred acre farm. Increase in the value of property is a pretty good indication of the service these roads are to the people of the country. Just think what that means. Every one hundred acre farm is increased in value to the extent of $500 to $2,000. With eight farms fronting on each mile of highway, it means an increase of from $4,000 to $16,000 per mile of road. With that increase, property can pretty fairly be assessed for the cost of a great portion of the roads. When you take from that cost the proportion the province is paying under the Highway Improvement Act, it looks like a pretty good proposal for any part of the country to construct good roads.

In proposing the construction of a main highway between Toronto and Hamilton, the people along that highway said, "If you will construct it, we will pay an annual frontage tax of one and a half cents per foot for thirty years." The people on that highway have consented to the plan, and it indicates that the principle, if extended and made applicable to certain other of the most important highways, could be serviceable and acceptable, and would help to create the fund necessary to construct good roads.

It is also argued, and very properly so, that the automobile should be specially taxed. I will not go into the question of the destruction of the roads from the use of automobiles. They unquestionably do considerable injury to the highways, especially heavy cars which travel at high speed over stone roads. But it is a notable fact that the automobile owners have consented to pay such a tax; which will no doubt be imposed.

Now the population of the towns and their assessment throughout Ontario is practically equal to the population and assessment of the townships; therefore, I take it that the people of the towns and cities are paying one-half of that one-third, or one-sixth of the cost of the good roads con-

structed under the Highway Act at the present time. One-sixth, I think you will agree with me, is not sufficient.

The Highway Improvement Act has been before the people of Ontario for some time. For over ten years, counties have been offered one-third of the cost of constructing main roads, and all of them have not yet jumped at the chance. I do not know just why they have not.

The Highway Act is extremely simple in its operation. The county is empowered to take over and maintain the main roads of the county highways used by the people of that county, and serving the market requirements of the people of the county. They appoint their own superintendent or engineer to direct construction for the county council. At the end of the season they send us their statement of expenditure and we pay them one-third of it. Up to the present time we have not had any serious trouble with any county. Sometimes they say we are a little slow, but we get there just the same, and they always feet sure of their cheque. The county council controls these main highways in the same way as a township council would manage their roads. By concentrating our efforts and energies on a special system of highways we follow a principle that is absolutely essential in any similar form of organization. In any line of construction you must concentrate sufficient energy on a fixed object to accomplish that object; to complete it and then go on to the next.

I have referred to organization. Organization, I am convinced, is the key-stone of the situation. If you get your organization as it should be, everything else will take care of itself. The superintendent should practically take the place, with county council, of a contractor. He should be the type of man who would be a successful contractor.

Another important part of the organization is the foremen. Part of the qualification of the superintendent should be that he is able to select and get to work for him, and with him, good and capable foremen. What is a foreman? The word "foreman" explains itself. It means the first man: the head man on the work, carrying out the instructions which have been given to him, and whose special duty it is to get the men, the teams and machinery to give fair and honest service on the road. Between the superintendent and the foremen, you have the essential features of an organization, and too much car cannot be taken in the selection of these men.

It is part of the duty of the superintendent to plan his work, and every foreman should be the first man on the job, with the day's operations well planned. Not only should the superintendent plan for carrying out the construction, but the foreman should come to his work each day with a clear understanding of what he is going to do. These are some of the features of the organization that we should try to build up.

Contract vs. Day Labor.—I am sometimes asked if it would not be well to construct roads by contract instead of under the county road superintendent and his foremen. In road construction, in my experience, in order to get as good results from a contractor as from your own foreman, you must spend too much on surveys and engineering supervision to get the contractor to carry out the work. Specifications must be so complete that they frighten the contractor and increase the amount of his tender. The contractor's risk is also greater than that of the municipality. I have seen sections where contract work had been carried out very close to day work, and going over those two sections, we could point out the parts which had been built under the county superintendent and those under the contractor. The time is approaching when, I believe, we can construct highways by contract, but for the simpler class of work, the best and cheaper results will come through carrying out the work under the superintendent and foreman. When we come to make provincial highways, such as are constructed as state highways, I can understand where the plant of the contractors can achieve excellent results, and his organization can be made of good use. But, up to that stage, I believe that the best and cheapest results can be obtained by doing the work under your own superintendent.

Freight Rates on Stone.—It is important to get stone, in a great many parts of Ontario, as cheaply as possible. There are parts of the province where there is plenty of stone. where the people would like to exchange it for some of the good soil of Essex County and Elgin. Down in Leeds and Frontenac there are points where they have so much stone that they do not go off the highway to procure it. But in certain parts of Ontario the only way we can build roads is to ship stone by rail. That is expensive; and there has been a feeling among the counties that the freight rates ought to be reduced. I believe so too, and we have placed the matter before the railway corporations from time to time. The last negotiations entered upon were the most hopeful I have yet undertaken, and I hope we may be able to get the freight rates on stone reduced. But we cannot control two ends of the string at the same time. The point has been raised that if we get the freight rates reduced, we are merely creating an opportunity for the quarry owners to increase their price for stone. If we can in any way get the cost of hauling the stone reduced, we shall expect to look after the other end of the problem.

It is the fact that in every township, if you have not good main roads at the present time, as soon as a good road is constructed, it becomes a main highway, it draws the heavier traffic from other roads. From this cause, townships can construct an inferior type of highway for branches from the main road, which will serve equally as well the traffic over them. My view is that every road in Ontario, travelled to any extent, should receive a due degree of care, and by proper organization in our townships, this can be done.

To get a system established in the townships, there are some essential steps. One is that you place your system on a cash basis. Collect what you require as a special levy on the assessment of the township, what your people can afford. When that sum is a sufficient amount, say $3,000 or $4,000, you should have a foreman appointed under the township council to take charge of the expenditure. By starting early in the year, he can, with the grading machine, grade the roads at the time of the year when earth is in a suitable state to be handled. We often see grading in progress on clay roads when they are as hard as bricks. That is a mistake. Road construction should go on at the time of year that is most suitable. The foreman should be out early in the Spring as soon as the soil is fit, to do all the grading that is required for the year. By using the log-drag on the roads after grading, for maintenance you do not have to repeat the grading operation and it becomes permanent. But the log-drag is useful only as you make it part of a system, and the organization of that system ought to be the duty of the township foreman. After the grading of the year is done, when the streams are low and the ditches dry, that is the time for him to build the small bridges and culverts. Gravelling, if there is gravel in the township, can be let by contract, and carried in when the grading is finished. In the fall, drainage should be completed. By employing a permanent foreman you create in him an experienced employee who will be able to bring that skill to play upon your highways such as other countries have found necessary.

On page 440 of last week's issue, in connection with the report of the Canadian Society of Civil Engineers, Mr. V. J. Elmont's name appeared as Mr. Almonte. The mistake was made as a result of the compositor following the copy as supplied by the verbatim report of the discussion.

STEEL FORMS FOR CONCRETE CONSTRUCTION.

The application of steel forms to conduits, culverts and drains is dealt with in the following article by William Mayo Venable. From his experience of many years on reinforced concrete sewage and drainage systems he is well qualified to write on this subject. In "The Cement World" of January, 1913, dealing with the use of steel forms as above, he writes:—

From the very earliest days of concrete construction until the present, the use of steel for building forms has been constantly increasing in favor. In the earlier days steel was resorted to occasionally by individual contractors who designed and built their own equipment to meet particular conditions, or by builders experimenting to ascertain some more economical method of providing for their centering.

The use of corrugated steel, either plain or galvanized, to support floor loads, both as temporary centering and to be left in place permanently, represented one of the earlier attempts to employ steel for concrete construction. This particular material, corrugated steel sheets, has continued in use for the same purpose, but has found a much wider field of recent years as lagging to support concrete floors of flat slab construction in those cases where the appearance of the corrugations on the ceiling is not considered objectionable. This is probably the most conspicuous instance of an early type of steel centre which has come into common use. The low price of corrugated steel and the ease with which it may be placed and moved on work of this kind without appreciable damage makes it the material which appeals to building contractors generally.

The application of steel in the construction of forms for engineering work generally, however, has been brought about largely through the efforts of a few concerns that are specializing in this line. The reasons for this are that the fabrication of steel cannot conveniently be carried on by individual contractors with the facilities which they possess, and that contractors generally are not usually sufficiently familiar with the requirements of steel form designing to be able to design their own forms and have them built for them. Aside from the fact that there are certain fundamental patents on steel forms, there is another reason which likewise has operated to cause the steel form business to be developed as a separate industry, and that is the very great advantage that accrues to the user of the form by being able to lease apparatus suitable for this work, instead of being obliged to pay the full price of having the forms made for his particular job.

Steel forms are in more extensive use in the construction of sewers, drains, conduits, tunnels and such engineering works than in any other kind of construction. Works of this kind possess certain characteristics that are not common to other types of work upon which concrete is extensively employed. They extend from considerable distances without change of section, and they are always, in whole or in part, composed of curved surfaces. A form to construct a sewer or an aqueduct must be designed so that it can be used over and over again very many times. It is not at all uncommon for a form to be used as many as 30 times over in the construction of a single sewer, while in building construction it is unusual for a form to be used over more than 3 or 4 times on one building. Thus, it is readily seen that the form for a conduit should be made much more durable than is necessary for a form which is not expected to be re-used more than a very few times. The use of steel for forms for conduit of all kinds provides a form which is not injured at all by depositing the concrete, but which will retain its shape indefinitely. This, however, is but one advantage of the use of steel on such work. In conduits of all kinds it is necessary to economize space in order that there may be room for the workmen inside of the conduit and also room for shifting the forms themselves. Wooden centres, in order to secure the necessary strength, occupy so much room with their bracing and other frame-work that it is very nearly impossible to arrange to shift them with the necessary degree of economy.

In conduit work there are two different methods by which the work may be carried on so far as the forms are concerned. Forms for one section may be set up, concrete deposited about them, and the forms then removed and carried forward for another section, the process being repeated thus until the entire structure is finished. If the work is carried on in this way it is not necessary to pull one set of forms through the conduit which is occupied by another set. The other method of conducting the work is to provide the forms for a given length of conduit and constantly to convey the forms from the portion of the conduit which is completed through the portion of the conduit which is being constructed, and to set them up in front, where the conduit is to be extended. It may readily be seen that with wooden forms the first of these methods implies taking the forms apart into many pieces, carrying these out of the ditch and assembling them again in a new position; while the second method implies taking the wooden forms apart in panels and conveying these panels forward through the bracing which supports the panels upon which the concrete is being placed. These are both extremely laborious and expensive processes with wood. With the use of steel forms they are rendered extremely easy.

On conduits of moderate size, where the depth of the excavation is not very great, it is usually found more economical to shift the forms from one position to another without conveying them through forms already set up. Steel forms when used in this way are provided with a carrier of some kind, usually a series of small wheels attached to the sides of the form, by which they may be conveyed forward without being taken apart at all. Thus 100', or over 200' of centering for a sewer may be moved at one time, it merely being loosened from the concrete by means of turnbuckles, lowered upon wheels and pulled out with a line to the new position in which it is raised to the proper height and braced to the proper width. This is called pulling the forms "en train."

Where a section is circular the same form may be used to form the invert as is subsequently used to form the arch, but usually the form for the invert is kept separate from that for the arch, the invert being built first and the arch built subsequently. In circular conduits a centre for either invert or arch consists of plates bent to a little more than half a circle, stiffened by angle-irons running longitudinally, joined together at intervals by simple fasteners so as to form a continuous trough, and placed in such a position that it may be collapsed or stiffened, if necessary, by means of turnbuckles.

A circular section is by no means adopted for most of the larger sewers or drains. In some of these structures the bottom, or invert, is made with sides having only sufficient inclination to keep them free from deposit when the conduit is in use. The side walls are often perpendicular for some little distance, and the arch semi-circular. This form of conduit can be built in three operations, viz., the invert, the side walls, and the arch; or may be built in two operations, consisting of invert and portion of side walls, and the balance of the side walls and the arch together. Modifications of this design are very common, in some cases the side walls being slightly curved. Egg-shaped and flattened elliptical conduits are often required, and these, as well as the circular, lend themselves to the use of steel in their construction. It

is, of course, obvious, however, that the circular and semi-circular sections, being in such common demand, can usually be constructed much more cheaply than other sections, because forms for them can be used on many different contracts in succession throughout the country. Engineers are generally well aware of this fact, and take advantage of it in making their designs. There is scarcely an important sewer system which has been constructed in this country in recent years upon which the half-round collapsible centre has not been used to a considerable extent.

Generally speaking, it is more economical for the contractor to build a sewer in two sections, the invert first and the arch subsequently, no matter what the cross-section of the sewer may be, than it is for him to pour the entire structure in one operation. It is also generally preferred by engineers that the invert shall be constructed and the forms removed for inspection before any work is done on the arch, and where sewers are reinforced with steel, the splice of the steel is generally made about the springing line of the invert. By dividing the work in this way the engineer is able to inspect the most important part of it, the invert, which carries the actual flow of water, without having to enter the finished conduit. It is also often preferred that the men should work in daylight rather than by artificial light to do any work requiring close inspection. There are, however, numerous occasions upon which it is considered essential that the structure shall be poured as a monolith, and in such cases it is necessary to build the form so as to make a complete circle, which may still be collapsed and removed conveniently, care being taken that the joints are so made that one or the other of the sections may be removed first. If the design is not very carefully worked out with this object in view, a full round centre is likely to bind, and become extremely difficult to shift.

Half-round centres to be pulled "en train" have been made and used of all diameters, from 2′ up to 25′. Usually however, the length of time that a centre must be left in place on a conduit of the larger size, and the necessity of arranging the work so that the concrete can be deposited every day, render it necessary on large work to design the centres so that they may be collapsed and pulled through one another. Just when it will be more economical to pull a centre "en train," and when it will be more economical to collapse it and carry it forward in sections ought to be determined in connection with each particular construction after careful consideration of the local conditions, the depth of the excavation, the arrangements for depositing concrete and the liability of the work to interruption or injury on account of having a greater or less amount of open ditch at one time. Wherever it is practicable to stretch out the work over a long distance without incurring any liability to damage, there will be a certain advantage in arranging the work in several sections and pulling the forms "en train," rather than in collapsing them and carrying them through one another; but on the largest work it is very seldom practicable to spread the work out in this way, and usually where the conduit is more than 8′ or 10′ in diameter more economy will be secured by building the centre in sections and collapsing one or two or three sections at a time and conveying them forward through the assembled sections of form to the new position.

On the large concrete sewers, aqueducts and drains built in recent years, it has been almost universal with contractors to collapse the centres sufficiently to convey them through other centres which are supporting concrete which has not yet set sufficiently to permit the centres to be moved. The best example of this method of working is found on the new Catskill aqueduct which supplies the city of New York with water. This aqueduct is 90 miles long. Throughout most of this length water is conveyed in a horseshoe conduit 17′ 6″ wide and 17′ high, built at a grade which permits the water to flow without completely filling the aqueduct. Other parts of the work are in tunnel, or on viaducts; while that portion of the work which enters the city of New York is in many places at a great depth from the surface of the ground. Practically all of this concrete has been cast on steel forms.

Where the work is conducted in open cut, these forms are collapsed and supported upon carriers in the finished aqueduct, and they are conveyed through the portion of the work which is yet under construction and expanded into position in front. The same method of handling the forms has been employed on the new sewerage systems at Louisville, Baltimore and East St. Louis.

Very large forms adapted to collapse and move forward in large units have been used on the locks of the Panama Canal and for the pressure tunnel of the Ontario Power Co.

In tunnel work, it is sometimes possible to utilize forms that collapse and pull through in units similar to those used in sewer work, but very frequently on account of the difficulty of getting concrete into place in tunnel work, it is necessary to carry on this work with a series of panels which are attached to ribs as the concrete is deposited. This method is extensively employed in tunnel work for railways and while not nearly so easy to handle as the form that can be moved in large units, it has proved to be eminently practical and economical in work of this class.

In all such work it is customary to build the forms especially to fit the design of the particular structure in view, and not to attempt to consider the form problem at all in the design of the concrete structure. Wherever the length of the conduit is sufficient, this is the most economical practice, but where the lengths of the conduit is not great it will be found more economical to use circular or modified circular forms upon which a standard steel form can be used,—a form which can be leased for the moderate rental—than to adopt a peculiar shape which will require a form built to order, and consequently an unnecessarily heavy expenditure for the form work. It should be remembered that where forms are made of wood to meet any particular conditions, they cost 12c. to 16c. per sq. ft. of form surface, and that if the walls of the concrete structure be thin, this amounts to over \$5.00 to \$10.00 per cu. yd. of concrete in place. In fact, the cost of forms on very many concrete structures exceeds the sum of all other costs entering into the concrete. The saving that may be made by adopting sections which will lower the cost of the forms is so great that every engineer should consider it in making his designs, more especially upon those parts of the system he is designing which are too short to justify the manufacture of special apparatus for constructing them.

The cost of a system of concrete storm sewers may very easily be reduced by 15 per cent. or 20 per cent. of what it might otherwise be by having careful consideration given to the cost of the form work, and so laying out the system before construction is commenced as to secure the greatest economy in this item.

All collapsing and conveying methods used on forms similar to those described for circular and horse-shoe shaped conduits are adapted to rectangular or box-shaped culverts such as are commonly employed in flat lands where it is necessary to build drains of large capacity without deep excavation. Box-shaped forms for drains with flat slab covers should be designed so that the same forms can be used on the various sizes of drains in any common drainage system, beginning with the largest on the main line of the system and extending to the smallest laterals. Forms of this kind are readily made in such a manner as to permit the removal of panels of various width so as to change the width and height of the conduit wherever necessary.

HIGH-SPEED BEARINGS.*

By John C. K. Balfry.

When considered in connection with the subject of this paper, the term "high speed of revolution" is somewhat misleading, for one should speak of the speed of journal surface rather than of speed of revolution. For example, take the case of a De Laval steam turbine having a shaft 10 mm. diameter revolving at 30,000 revolutions per minute, and compare the surface velocity of it with that of a steam turbine shaft of 100 mm. diameter revolving at 3,000 revolutions per minute. The surface velocity of each is about 51.6 feet per second, but the speed of revolution of the first is ten times that of the second.

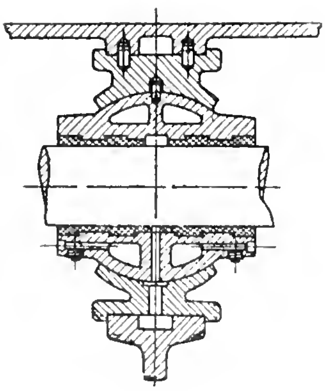


Fig. 1.

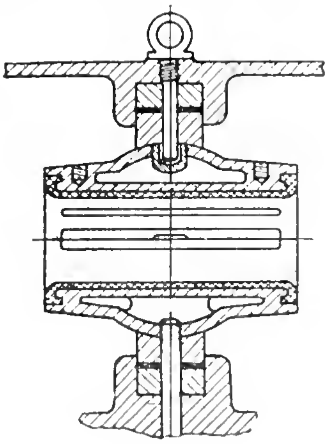

Fig. 2.

With rotary machines of the turbine or electrical kind, it may be considered that surface speeds of 50 feet per second are quite ordinary, and 100 feet per second as high. Pressures, per unit area of projected bearing surface, in common use with the kinds of bearings under consideration are small when compared with those met with in, e.g., modern railway practice, where 300 lb. per sq. in. of projected bearing surface is not at all exceptional in the case of driving axle journals; but the conditions under which these work are very different. Briefly, 50 lb. per sq. in. of projected bearing surface may be considered ordinary, and 90 lb. per sq. in. high for bearings of the class being dealt with.

Steam Turbine Bearings.—These may be grouped under three heads: (1) Rigid bearings; (2) swivel bearings; (3) concentric ring bearings.

1. By a rigid bearing is meant one wherein the shell is held rigidly in the housing or pedestal surrounding it. It is adaptable where shaft deflection is very small, the slight slackness or clearance between the journal and the bearing, and also the presence of a film of oil around the journal, being taken advantage of. Obviously, these bearings are of use only where journal centres are comparatively small.

2. The swivel bearing is no doubt the most widely used kind in turbine practice to-day. Its name indicates one of its outstanding features. It is adaptable practically to all kinds of turbines and generators. It allows itself to radiate in the housing about its centre, thus accommodating itself to the deflection of the shaft, so that its use with shafts having great length between journal centres is almost universal. It is easy to design the shell in such a way that lateral and vertical movement, required for alignment when bearings are being set at a considerable distance apart, is readily attained.

3. The concentric ring bearing has characteristics which are set forth in the description of it which appears further on.

The shell of the "rigid" type of bearing is usually made of good, close-grained cast iron, and is lined on the inside with white metal; babbitt, delta, or magnolia metals are found suitable for this purpose. It is turned on the outside of the shell to fit the pedestal, in which it is prevented from rotating by means of dowels engaging in holes in the cap or cover of the housing; a flange at each end prevents end movement. There are, of course, other methods of preventing rotation and end movement, but the above is perhaps the simplest. If it is found necessary to water-cool such a bearing, the problem is much simpler than that which presents itself when the same treatment is desired for a bearing of the swivel type.

A bearing of the rigid type is fitted to a 2,000 kw. steam turbine of the A.E.G. type. In this instance the shell is made of brass, and is lined with white metal. Among the interesting features it possesses may be mentioned that the oil, before being admitted to the journal, is passed around the space between the housing and the shell to render the oil thinner before use. This appears to have a double effect on improving conditions of working—the shell is cooled by the circulating oil, and the friction losses in the bearing are reduced by the higher oil temperature. The surface speed of the journal is said to be 96 ft. per second.

The Swivel type is illustrated in Figs. 1, 2, 3, 4 and 5. Fig. 1 is used with a Melms Pfenninger steam turbine of 3,000 h.p. at 1,500 revolutions per minute. It is 180 mm. diameter by 380 mm. long, and the journal surface speed is 46 ft. per second. The shell, which is made in halves, is of cast iron, and is lined with white metal. The temperature of the bearing can be kept below the danger point by circulating water through the chamber shown. A cage is provided giving ample bearing surface for the shell. The housing is, of course, on the outside, the cage being provided with lugs to prevent end movement. Dowels prevent cage and bearing from rotating. Oil is fed under pressure into the annular space in the housing, through a hole in the bottom of both cage and shell, into a partly annular space around the journal.

Fig. 3.

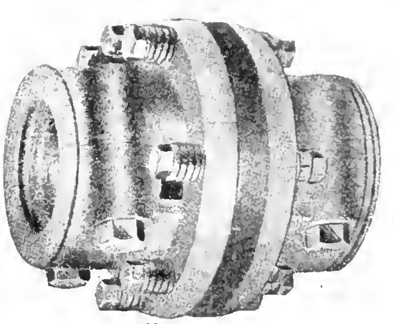

Fig. 4.

Fig. 2 illustrates a bearing used with a 1,500 kw. 1,500 revolutions per minute steam turbine made by the Brush Electrical Engineering Company. The shell is hollow, and is lined with white metal. The diameter of journal is 5 in., and length 15 in. The bearing is capable of being easily aligned both vertically and laterally, shinplates being provided between the cage, which is immediately without the shell, and radial pads which are screwed to the cage. Both shell and cage are made in halves, and both are prevented from rotation in

* Paper read before the Rugby Engineering Society.

the manner shown, end movement being prevented by the flanges forming part of the housing. It is interesting to note that the oil, before being admitted to the journal, is passed through the hollow shell. Grooves arranged longitudinally, and well chamfered on their edges, are provided in the top half of the bearing surfaced. The surface velocity is about 33 ft. per second.

The kind fitted to a Zoelly steam turbine of 200 h.p. at 3,000 revolutions per minute is of cast iron, lined with white metal. Lubrication is effected by six rings arranged in two chambers containing three rings each. The bearing is water-cooled, water being supplied to and returned from the hollow shell through two unions screwed into the top half of the shell; these are not illustrated. The ringed shaft is provided for expansion purposes, and keeps the shell and shaft always together. This bearing is 60 mm. in diameter by 250 mm. long, the surface speed being 31 ft. per second. Oil, after being carried to the upper surface of the journal by means of the rings, is distributed to the surfaces along grooves in the white mdetal. These grooves or channels "take in" at the top on both sides of the ring chambers and spread away spirally, returning again to the chamber farther round the shaft. By this means an effective method of lubrication is obtained.

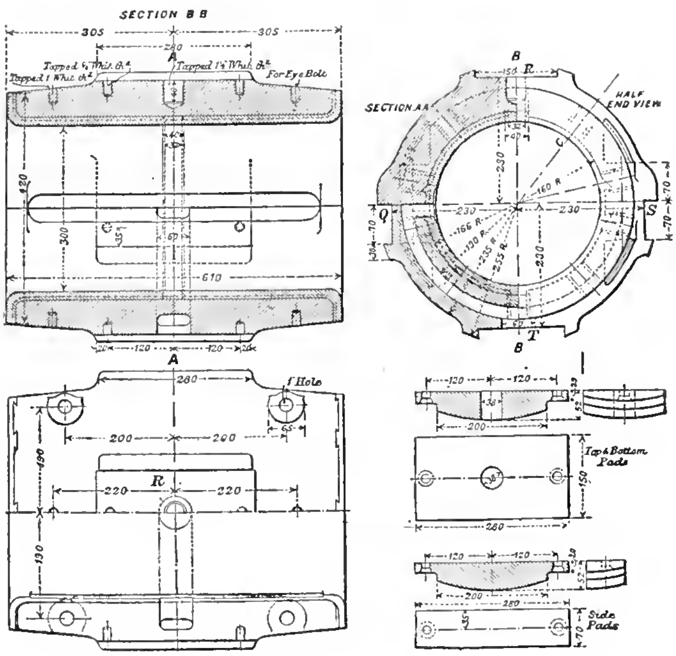

Fig. 5.

Fig. 3 is an illustration of a bearing fitted to steam turbines made by the British Thomson-Houston Company, Limited. It possesses several interesting features, among them being its "clean" finish and simple design. It consists of a cast-iron shell lined with babbitt metal; the shell has spherical seats, and the bearing is made in halves. Oil is delivered into a groove in the white metal and along the horizontal centre line, and is drawn down by the rotating shaft. On the side opposite to the oil inlet a second groove is provided, but it differs from the groove on the inlet side in being open at its ends thus allowing oil that has passed under the shaft and has become heated to pass easily away at the ends of the bearing. Lubrication and cooling of the upper surface of the journal is effected by means of grooves leading from the inlet groove diagonally.

Fig. 4 shows a bearing which has important characteristics. It is fitted to generator shafts at the exciting end of the rotor. When a turbo-generator is passing through a critical speed there is a tendency for the shaft to "whip." In order to destroy this action anl ensure that the shaft will pass through a critical speed with absolute safety, the bearing sleeve is permitted a small amount of radial play between friction collars. This bearing, it will be noticed, is made in halves, and the radial sideplates or collars are bolted in an elastic manner to the shell. It is made by the British Thomson-Houston Company, Limited.

A bearing such as is fitted to turbines of 7,000 kw. capacity when running at 750 revolutions per minute is illustrated, together with its accessories, in Fig. 5. It consists of a cast-iron shell to which is secured at four positions the pads which allow the bearing to swivel about its centre. The swivel pads are shown in the right-hand bottom corner. It will be seen that the shell is made in halves, secured by comparatively small bolts and nuts. The interior is lined with white metal cast by the "Eatonia" process. The oil is conducted from the bottom of the shell along the two oil-ways shown up to the horizontal centre line; there it feeds the two wide channels arranged on each side of the bearing. These channels are well bevelled at their sides, and extend almost the whole length of the lining, and have a sealing piece at each end. These bearings represent a design which Messrs. Willans and Robinson, Limited, have used on both large and small steam turbines.

The Parsons concentric-ring bearing consists of a gun-metal sleeve in which runs the journal. The sleeve is surrounded by two or more gun-metal rings arranged in sets, and separated by an oil or lantern ring. The whole is mounted within a heavy cast-iron outer sleeve, to which the innermost sleeve is lightly secured at one end. This outer sleeve is spigoted to the housing only, and not to the cap, by means of a loose cast-iron half-ring which fits in the groove stem at the bottom.

If it is desired to remove the bearing, the cap is first removed, and the half-ring rotated until it is free of the pedestal and bearing. It is then possible to slide the bearing endways off the shaft. There is a clearance of a few thousandths of an inch between the rings and sleeves. Oil finds its way into these spaces, tnd thus there is a hydraulic cushion which dampens those vibrations which are inseparable from shafts having speeds of rotation.

COAST TO COAST.

Toronto, Ont.—At a meeting of the Hydro-Electric Power Commission held recently an important change in policy was decided. Hereafter the Commission will not acquire easements for right-of-way but will expropriate the necessary strip, 66 feet wide, required for transmission lines. This departure will apply to the extension of the Niagara transmission line from St. Thomas to Windsor as well as other contemplated extensions in the Midlands district and in eastern Ontario.

Montreal, Que.—In the course of the work of the Mount Royal tunnel many interesting speciments of rock have been met with and definite proof of the volcanic origin of Montreal's mountain obtained. The indications, according to the engineers, show that the mountain was at one time either an active volcano or that lava forced its way up a central orifice, bursting and breaking the summit of the mountain, but possibly never actually spouting forth as an eruption. Numerous fossils have been found and also a particularly fine specimen of crystallized calcite. Copper and iron pyrites are also evident in some of the rock.

Montreal, Que.—The experts working on street car congestion of this city have prepared their report for the Mont-

real Tramways Company. These plans cover a gradual development designed to be spread over the next couple of years, and eventually the development will care for the population for the next ten or twenty years.

It is stated if the proposals of street extensions, etc., are carried out, the company will find it necessary to order 2 o cars in addition to the 200 now on order. The total expenditure will amount to from $8,000,000 to $10,000,000, which the company is fully prepared to make.

Providence, R.I.—The Narragansett, the first of the Grand Trunk boats for Atlantic coastwise trade, from the shops of Harlan and Hollingsworth, Wilmington, Del., has been launched recently. The Manhattan, a sister ship, will be launched later. Both have been designed by Mr. Kirby, of New York and Detroit, a well-known marine architect, who has designed some of the largest steamers on the Great Lakes. These vessels have been built for the Central Vermont Transportation Co., and were financed a year ago by the sale of $1,500,000 bonds. The Narragansett is of steel, and has a capacity for 700 passengers and 500 tons of express freight. The Narragansett and Manhattan will ply between Providence and New York.

Sarnia, Ont.—Wireless machinery is being installed in the wireless station at Point Edward by the Canadian Marconi Company, which will be in charge of the station and will operate it for the government on a percentage basis. The apparatus consists of two sets of dynamos connected engines, so that if one machine with two eight-horsepower gasoline breaks down, the operator will have a second generator to fall back on. The sending radius of the machines will be 300 miles and will enable the station to work with the Soo on the west, or Ottawa on the east. The receiving machines will be able to take a message from any of the high tension stations on the continent as long as the sending station is strong enough to send out the waves this far. The station will be used by the government as well as for sending telegrams for the public. The charges will be considerably lower than those of wire lines.

British Columbia.—Work has been begun by the Northern Construction Company on the Lulu Island branch of the Canadian Northern Pacific Railway. The first camp has been established six miles below New Westminster and a second will be located a mile further west. The latter will undertake the construction of the two miles of trestling across the muskeg which exists here and for which two million feet of lumber will be required. According to Mr. J. M. Mercer, general manager of the construction company, this line will be completed by the end of May. The line from Port Mann to Yale is now nearing completion but it is not expected that a train service will be operated until about midsummer. All the stations from Port Mann to Yale have been named and the contract for their construction will be let in a few days. These stations will be Port Mann, Langley, Glen Valley, Mount Lehman, Matsqui, Sumas, Mountain, Chilliwack, Rosedale, Popkum, St. Elmo, Floodville, Hope, Trafalgar, Yale.

Washington, D.C.—The failure of Congress to enact legislation at the session just closed to extend the Burton Act which limits the amount of water diverted on the American side of Niagara Falls for power development to 15,600 feet, means that the Americans can increase the amount of water used for this purpose and that they may import more power generated on the Canadian side.

The treaty between the United States and Canada provides that 25,000 feet per second of water may be diverted for power purposes for each government. The Burton Act restriction, which was originally demanded by the American Civic Associations and other organizations, who feared unrestricted use of Niagara's waters would ruin the beauty of the Falls, has been extended twice.

Several American companies are preparing to import power from Canada and use the plants and machinery that have been idle since the enactment of the Burton law. Governor Sulzer states that in the absence of federal legislation the jurisdiction of the extra 4,450 feet of water permitted under the treaty with Canada, automatically passes to New York State.

Ottawa, Ont.—Mr. Clyde Leavitt, Chief Fire Inspector for the Railway Commission, and Forester for the Commission of Conservation, is now preparing a statement showing how the installation of the use of crude oil for generating locomotive power in stead of coal, may prove more advantageous to railways from a financial standpoint.

The Canadian Pacific Railway is now using oil-burning engines on its main line between Kamloops and Field, B.C. The Grand Trunk Pacific and some of the Canadian coast steamships also burn oil, while the new system is now in use on many of the railroads in the United States. The greatly decreased smoke, the decrease in the number of firemen required, the economy particularly in intermittent service, and the fact that three boilers heated by oil will give the same amount of steam as the same number heated by coal, all tend to make this new system popular.

The oil is obtained from the oil fields of California, and if future discoveries in Alberta and British Columbia make this oil more plentiful its use will be largely extended on Canadian railroads.

The use of this new fuel would greatly lessen the necessity for forest protection from flying sparks and cinders, and greatly decrease the loss experienced annually by the country from this cause.

Vernon, B.C.—This city recently opened a splendid new power house with a demonstration in which several hundred citizens participated.

The chief point of interest was the new Diesel oil engine which has just been installed, and the operation of which will enable the city to give the citizens the lowest lighting rate in British Columbia, and power rates unequalled by any city of its size in Western Canada.

The oil plant will be used continuously, the steam plant being used for auxiliary during the hours when the load is heaviest, until another 50 h.p. engine is installed and which the increased demand for power necessitates.

PERSONAL.

MR. F. N. NEWMAN, manager of The Canadian Fairbanks-Morse Co., Limited, of Toronto, is on a trip to England.

MR. F. J. ANDERSON, B.A.Sc., O.L.S., of the firm of Anderson and Berry, engineers, has been appointed city engineer of Niagara Falls, Ontario.

KESTER BARR has resigned his position with Manning, Maxwell and Moore, Inc., of New York, to take the position of manager of the Lumen Bearing Co., West Toronto, to succeed Mr. Fred Ganderton, resigned.

ARTHUR H. BLANCHARD, M.Can.Soc.C.E., Professor of Highway Engineering, Columbia University, has been appointed by Governor Sulzer a member of the Advisory Commission on Highways for the State of New York.

MR. H. M. MORROW, formerly assistant manager of the Asbestos Corporation of Canada is now in the employment of The Canadian Fairbanks-Morse Co., Limited, at Montreal, and will be associated with the motor truck department.

V. J. ELMONT, A.M. Can. Society C.E., read an interesting paper on "Trusses without Diagonals in Reinforced Concrete," before the Canadian Society of Civil Engineers on

the evening of March 6. Following the reading of the papers and the showing of a number of lantern slides, a discussion took place in which Prof. Mackay, J. A. Jamieson and others took part.

OBITUARY.

GEO. H. PEDLAR died suddenly at his home in Oshawa while preparing for a business trip to Chicago. Deceased was 70 years of age, and was president and manager of the Pedlar People, Limited, a company he established over 50 years ago, and which through his ability, became a flourishing concern, having at present offices in Toronto, Montreal, Ottawa, London, Chatham, Winnipeg, and Vancouver. He was throughout his busy life actively interested in public and social affairs and a generous giver to all charities.

SOCIETY NOTES.

At a meeting held March 14th, the following officers of the Engineering Society of the University of Toronto were elected: President, F. E. Mechin; 1st vice-president, F. S. Rutherford; 2nd vice-presidents, R. E. Laidlaw, K A. Jefferson, C. K. MacPherson.

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, T. S. Young, 220 King Street W., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson, Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase, Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto. Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O , Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

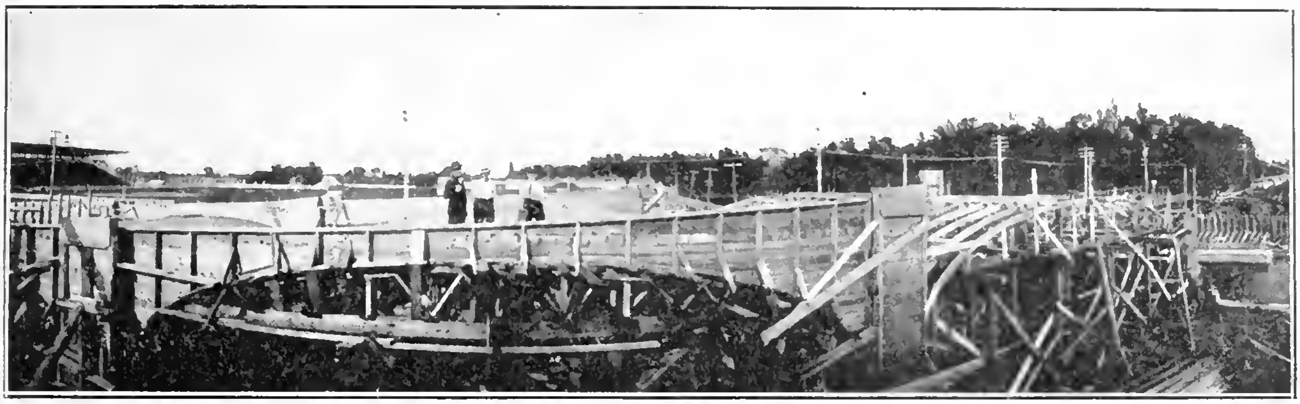
The Canadian Engineer

An Engineering Weekly

BANK STREET HIGH LEVEL BRIDGE, OTTAWA

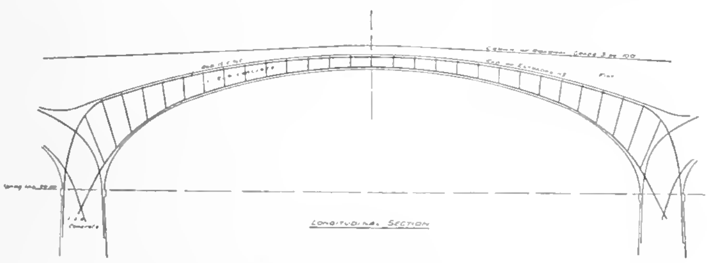
BY L. McLAREN HUNTER*

The Bank Street high level bridge, which is being constructed over the Rideau Canal by the city of Ottawa, is more than two-thirds completed. This new crossing will considerably help the development of Ottawa South, as it will enable the electric railway to cross the canal at this point. This they have been wanting to do for some time, as the traffic along Bank Street to Ottawa South is so very heavy; in fact, the heaviest in the city. The new bridge is badly required, as the old swing bridge was quite inadequate—to say nothing of the constant delay and congestion of traffic due to passing barges and boats.



Bridge Under Construction.

The bridge is designed to allow of the uninterrupted passage of boats and barges along the canal (and also for heavy highway traffic) having a clearance of twenty-nine feet above water level.



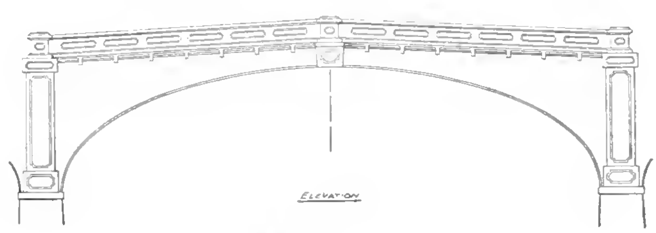
Longitudinal Section.

The main channel is spanned by a seventy-six-foot arch with a rise of 17.5 feet. The south approach consists of one arch span 62 feet, rise 14 feet; one arch span 50 feet, rise 11.5 feet, and about 30 feet of retaining wall, which completes the approach to the north side of Echo Drive. The north approach consists of three arches with spans 62 feet, 50 feet, and 40 feet, and rises of 14 feet, 11.5 feet and 8.7 feet respectively, and 230 feet of retaining wall.

The south abutment of the bridge (a section of which is reproduced) is of a 1:3:6 gravel mixture up to the springing line. At the base it is 25 feet 6 inches, and at the springing line 10 feet. The height of the abutment to the springing line is 24 feet.

The piers are of the same proportions as the abutment; they all rest on a good, sound gravel, free from clay of any kind, and are carried about five feet below the canal bottom.

The main arch is 76 feet, with a rise of 17.5 feet. A 1:2:4 mixture of broken stone concrete is used, reinforced top and bottom with ⅞-inch square steel bars placed 12-inch centre to centre, and tied together both vertically and horizontally with ½-inch square steel bars at 3 feet centres.



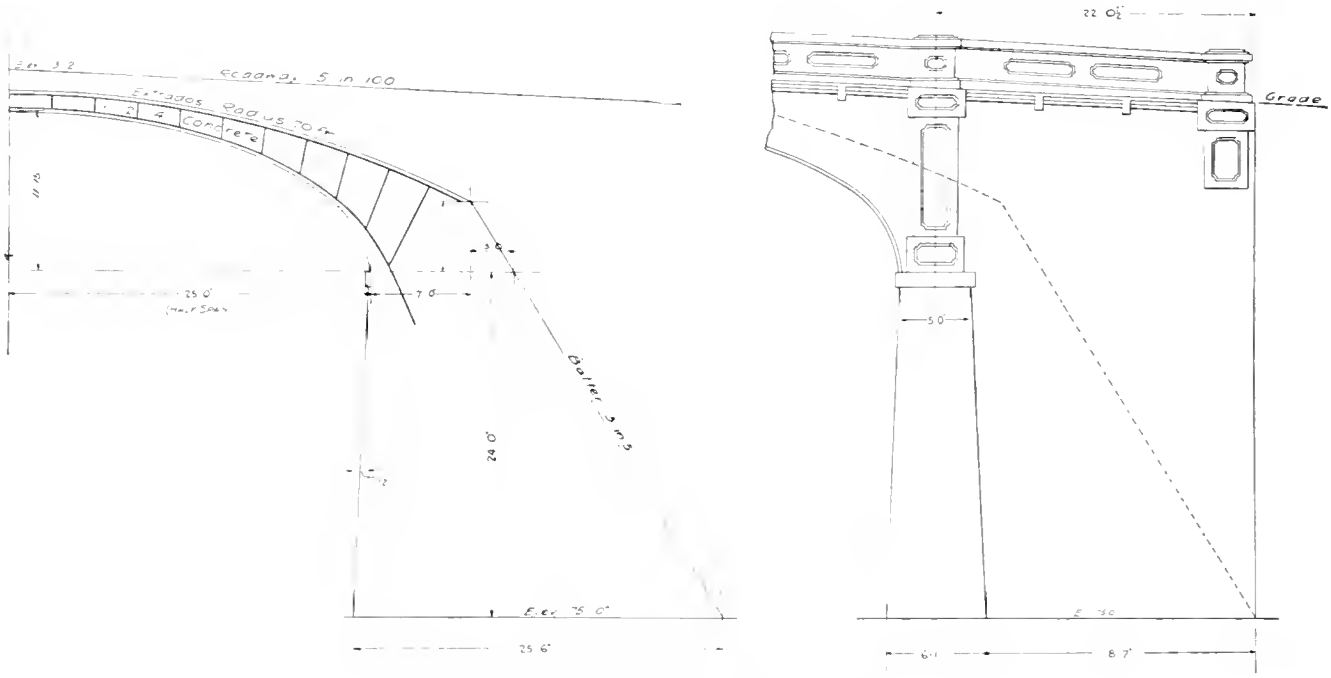
Elevation of Span.

The whole structure has been designed to conform with the specifications of the Department of Railways and Canals.

The Ottawa Improvement Commission's driveway will be continued under the north arches, through to the exhibition grounds, along the north bank of the canal as at present.

* City Engineer's Department, Ottawa.

The roadway, which will have a grade of five per cent. on both approaches, will be 40 feet between walks, and will be paved with creosoted wood blocks. The sidewalks will both be eight feet in width, and conduits will be placed under them to accommodate the cables and wires of the different electrical companies, thus doing away with the unsightly overhead wires. The ornamental lamp posts will be combined to carry the trolley wires of the electric railway and a cluster of four lights.



South Abutment, Bank Street Bridge.

Top of Arches With Reinforcing Bars in Place.

The construction work is nearing completion, everything being completed excepting the main arch, which has the centering and reinforcements ready to receive the concrete. This will be done immediately milder weather is encountered.

During the summer months between sixty and eighty men were employed; the number varying with the particular work in hand. Two steam derricks and two Smith mixers were kept constantly at work. A larger plant would have been difficult to handle, owing to lack of room at the site.

In concreting the arches, the concrete already mixed was hoisted with the derrick boxes to a temporary platform above the arch, and these emptied from it into wooden flumes which carry it to its place. Great care was taken to see that all the reinforcing was properly held in place among concreting.

The total estimated cost of the bridge, including land damages, is $130,000. Messrs. Jones and Girouard, of Ottawa, are the contractors.

Mr. S. D. Parker is the resident engineer on the works.

PORTABLE MIXING PLANT.

The new piers and wharves of the Balboa terminals, Panama Canal, will be supported on concrete caissons, sunk to rock. A portable concrete mixer mounted on cribbing on a flat car so that the spout is 14 feet above the platform is coupled to a box car containing cement, and at the "flat's" other end are alternate cars of sand and crushed rock. Portable runways for wheelbarrows are laid along the tops of the cars. The train is moved ordinarily by an air winch which draws through stationary sheaves at the ends of the track a ⅝-inch hauling cable with connections to the ends of the train.

When the train has been "spotted" opposite a form which is ready the concrete is poured into it through a chute. As it falls from the chute it is caught on a circular wooden platform set over the inner shell, and distributed to the annular space by men with hoes. The placement is quite simple and proceeds at the rate of mixer output. As soon as the shell has been cast the train is moved to another form. The concrete is allowed to set for 24 hours and then the forms are removed and cleaned at a special platform for their storage, after which they are set up again on the operating platform. The caisson shell is allowed to harden for three days before removal to a storage yard. Each section of shell is six feet high, with an inside diameter of 5 feet 6 inches and a thickness of shell of one foot, and contains 4⅔ cubic yards of concrete.

PORTLAND CEMENT TESTS.

At the meeting of the International Association for Testing Materials, the question of accelerated tests for constancy of volume in Portland cement, was under considerable discussion. In last week's issue of *The Canadian Engineer* we published a portion of a paper by Professor Max Gary as regards tests of this description in Germany. That portion of Professor Gary's paper which deals with accelerated tests in France is now given.

Accelerated Tests in France.—According to the paper by Mr. J. Bied during the last 20 years or so, hot water tests have been currently applied to hydraulic binding media in France, and the employment of the Le Chatelier needle cylinder apparatus for this purpose has been absolutely general and free from any objection. It is therefore perfectly natural that a French industrial laboratory should have taken up the matter of investigating the value of the objections raised against the method by the committee on the time of setting and by Messrs. Strebel in Germany and Butler in England.

Having read with a fair amount of attention the publications on this subject, I think that, leaving out of consideration the question of knowing whether or not the expansion in cold water previous to immersion in hot water should be disregarded—which point is quite independent of the test itself—the objections urged against the Le Chatelier hot test can be reduced to three:—

(a) The test would lead to the rejection of cements which would have behaved well in cold water.

(b) If the test be applied immediately after grinding, it will lead to the passing of cements which would, on the contrary, be rejected if the test were not applied until after aeration for a fortnight or a month.

(c) Finally, the test lacks precision, and furnishes results deficient in concordance, when employed in the same or in different laboratories.

These three objections will now be examined in turn.

The Le Chatelier test is likely to cause the rejection of good cements.

Here it is at once necessary to state the case properly, which does not seem to have been done. From a general point of view, the reproach is perhaps well founded, for I have kept in my laboratory for several months specimens of cements which gave an expansion of 50 mm. under the Le Chatelier test without exhibiting any trace of expansion in cold water. If, however, one takes up the point of view of the consumer, the reproach is unfounded, for the two following reasons:—

(a) The Le Chatelier test seems to eliminate all bad cements; and this is the main thing.

(b) Any manufacturer who knows his business can, without any sensible addition to the cost of production, make cements that will pass the Le Chatelier test.

Though it is not my place to point out what means should be adopted to attain this result, I am certain that many manufacturers, and those not the least important, will be entirely of my opinion.

Under these conditions the question of knowing whether the Le Chatelier test eliminates certain good cements should not even be mentioned by cement makers. The consumers are the best judges of the guarantees with which they should surround themselves, whilst the only part the manufacturers should play is to advise consumers on the possibilities of manufacture.

In the present instance, however, it is possible, without increase of cost, to manufacture a cement which will satisfy the Le Chatelier tests; and it is for the consumers alone, and not the manufacturers—one would think—to take up the matter.

It would seem, a priori, that the fact that cements which, though non-expanding when freshly ground, expand after aeration is due to the action of the added calcium sulphate on the calcium aluminate present in the cements.

A long time ago Candlot showed that cements which are retarded by the addition of gypsum, resume their quickness of setting after being aerated. According to Camerman, this little recognized phenomenon is the real cause of numerous accidents.

The company with which I am connected only makes cements which are excessively siliceous and do not contain more than 2 or 3 per cent. of alumina, so that it might be expected that the tests essayed with these would be less decisive than in the case of normal Portland cements. Nevertheless, they were not sufficiently so to be worthy of consideration.

A check specimen of the siliceous cement was mixed with 1, 2, 3 and 5 per cent. of its own weight of gypsum. The Le Chatelier test was applied immediately after mixing, and also after storage for 15 days in the open air.

Eight cylindrical test pieces were prepared from each product, and all the moulds were new and from the same source. After being made, they were kept in water at 17 deg. C. for 24 hours, between two sheets of glass, and then immersed in cold water in a water bath, the temperature of which was raised to 95 deg. C. in half an hour, and maintained thereat for 4½ hours.

A summary of the results indicates that aeration lessens the expansion of the check specimen and of the cements containing 1 and 2 per cent. of added gypsum, but increases the expansion of the test pieces with 3 and 5 per cent. of gypsum. The increase, however, is too small for the experiments to be considered decisive, and they consequently need to be completed.

The third objection urged against the Le Chatelier test is lack of precision.

It would perhaps be interesting in the first place to define what is to be understood by precision. There is no doubt that the Le Chatelier test does not attain the precision sought and obtained by Regnault in his experiments; but that it is not at least quite as accurate, as the other customary tests applied to hydraulic binding media remains to be proved.

After a series of tests carried out with new moulds from the same source, we have investigated successively:—

(a) The influence of the width of the shoulders by which the needles are fixed on the test pieces;

(b) the influence of the age, or degree of wear, of the moulds;

(c) the influence of the method of storage;

(d) the influence of the time elapsing between the final setting of the cement and the immersion in hot water.

From this series of tests it may be concluded that the form of the needle shoulder, and the age of the moulds, or rather the extent to which they have been used, have an influence on the results obtained, while the mode of immersion has but little influence; and that, on the contrary the results are influenced considerably by the time elapsing between the definitely ascertained completion of setting and the immersion of the test pieces in hot water, at least in the case of products with slow initial setting.

It is, in fact, characteristic of the Le Chatelier test that it does not give the measure of the absolute expansion at a given moment, but rather the difference between the effort of expansion and the effort of resistance opposed to this expansion by the cement in consequence of its own previous hardening.

May one not, however, base on this fact for the purpose of removing the reproach that the Le Chatelier is excessively severe? It would be sufficient to examine merely whether the delay of 24 hours after mixing is adapted for all eventualities, or whether it is not too strict, and that by altering the period to 36 or 48 hours one would still meet with the inconvenience of eliminating the cements that are stable in cold water. Moreover, in our opinion, the period allowed to elapse previous to the immersion in hot water has nothing to do with the value of the test. It should be left for each user to fix for each class of cement the period that should be allowed to elapse before the Le Chatelier test is applied.

On the other hand, the results obtained having revealed the slight influence of the method of keeping and of immersion of the test pieces in hot water, and the complete concordance of the tests performed with moulds of one and the same origin, it is in our opinion justifiable to regard the Le Chatelier test as being sufficiently accurate in practice and convenient for use. As regards the shape of the needle shoulders, nothing is easier than to contract this by regulation, in the same manner that one can fix the number of times the moulds may be used before being discarded.

WASTE DESTRUCTION.

Writing in the Municipal Journal, C. E. Crichton, M.D., Commissioner of Health, Seattle, Wash., has the following to say concerning waste destruction in the city of Seattle:

The term waste, as used in the city of Seattle, includes everything on earth that is wasted, deposited or thrown away as being of no further value to the person or persons producing the same.

The city of Seattle, after an exhaustive investigation made, has seen fit to divide this subject into three headings: 1st, Collection; 2nd, Removal; and 3rd, Destruction. The commissioner of health of this city spent one year in visiting the principal foreign nations, the different cities of Canada and the United States and made an exhaustive study of the methods of collection and disposal of waste material.

He believes that by far the most dangerous substances which should be collected and destroyed by the ordinary American city, are those which as a rule receive the least attention. Most cities attempt to make a regular collection of what is generally known as garbage, decaying vegetable and animal tissues. Many American cities collect only at convenient times, and some only once or twice a year, other wastes, which in Seattle are considered the most dangerous. We refer to old mattresses, sheets, soiled bedding, wall paper, carpets, rags and handkerchiefs which have been soiled by direct contact with the evacuations and secretions of those sick with typhoid fever or other communicable diseases, more particularly tuberculosis.

In visiting 28 of the leading cities last summer we found some of those classed as progressive and modern collecting this most dangerous waste only twice a year. It can be seen at a glance that, while table refuse or true garbage may become annoying to the special senses, the material is as harmless as it was before it passed through the kitchen. It is, of course, a feeding ground for flies and rats and to a certain extent furnishes a breeding place for the former.

We adopted the single can collection, into which every known substance is thrown and same collected regularly, because by so doing we cause an immediate destruction of the dangerous wastes and because it gives a mixture of ashes and other wastes with true garbage. It has been found by actual experience to limit the smell from the garbage can and the ashes, being a good absorbent, keep the insides of the cans comparatively dry. This step also enhanced the beauty of the city, since rubbish and refuse are never in evidence for more than a week's time. First of all, let us say that the collection and destruction of garbage was considered as a sanitary measure, and that the cost of collection, removal and disposal was subordinated to that of sanitation. After we had decided upon the most sanitary plan, we then sought to procure the most economical method of collection, removal and destruction.

We have given the matter of removal separate treatment because this city introduced the method of removing its waste by auto truck two years ago and to-day is removing nearly 30 per cent. of its waste in this manner. It is believed that within sixty days more than 50 per cent. will be removed by the auto truck. The removal of a city's waste is much more important than is conceded by most city officials. In removing the same by auto truck the material is taken through the streets of the city in about one-fourth or one-fifth of the time consumed by horse-drawn vehicles. Seattle is a city of hills and it is therefore safe to say that this material is removed as a matter of fact in one-fifth of the time consumed by horse-drawn vehicles. Six tons are removed in one truck bed built for this purpose. It is more easily covered by tarpaulin than would be the same tonnage in three vehicles. It is dumped once instead of three times, thus saving the blowing about and dissemination of disease-bearing germs. Not as many garbage-laden vehicles pass through a given community nor are they repugnant to the people as are horse-drawn vehicles. The collections are more regular because our hillsides are slippery during certain seasons and we were occasionally delayed a day or so at a time, as the case might be, by the use of horses.

In considering the great question of disposal, the one idea dominating at all times was that purification and destruction by fire was far and away superior to any other method. As a consequence, we early adopted the Meldrum Brothers furnace, of Liverpool, England, which is a forced draft, high temperature furnace and did what every American city should do, provided it adopts such a furnace, and that was to buy the right to the patents to build these plants, as many as desired within our corporate limits. This foresight has enabled the city to have in operation to-day three of these destructors, capable of consuming slightly more than 200 tons of mixed waste daily. Right here let it be thoroughly understood that not one pound of fuel is used in our destructor other than the waste itself—no coal, no wood, no oil. We have in the treasury to-day funds for the building of two more units. A unit has a guaranteed capacity of 65 tons of garbage daily. The Heenan & Froude incinerator now operating in Milwaukee is a type of furnace very similar to the one used here. Such furnaces turn out a clinker, or more properly speaking a slag, which we run through regular rock crushers and which is used for practically the same purpose as is crushed rock. We find a steady market for this material for use in paving and sidewalking, and especially for floors in fireproof structures. We sell at the bunker, receiving 75 cents per cubic yard. We also grind the clinker still finer when it is used for many purposes like the manufacture of stationary wash trays, etc.

The wagon which Seattle has adopted for general waste collection is the old type of European rear dump with large hind wheels and small front wheels which allows for turning within the length of the wagon. The rear wheels being high gives us ample opportunity for dumping large bulky material without annoyance. In one single can collection are boxes, barrels, shrubs, limbs of trees and other matter, and as a consequence there must be considerable clearance from the wagon-bed to the ground or there will be difficulty in dumping. Where we are dumping into the bunkers this is not quite so important, although it has its advantages.

The can which we allow to be installed must not contain more than 35 gallons, and is about 18 x 30 inches in size. However, for waste-paper we allow a larger can. Cans must be placed in suitable and accessible locations where they can be conveniently handled and loaded, since the time consumed in loading a ton of waste when taken from cans convenient and accessible as against cans inconveniently located amounts to practically 27 per cent.

We have not been operating with the auto trucks long enough to know exactly what the saving is amounting to over the horse-drawn collection. It is our opinion at this time, however, that we are collecting with the auto truck our waste at a saving of not less than 45 cents on the dollar. We have attempted to lessen the price of the haul by installing at different places in the city small bunkers arranged in cells, each cell having a capacity of about six tons. These are filled by the horse-drawn vehicles. This material is taken from the bunkers by the auto trucks to the incinerators and also at the present time to a large open dump. Five of these auto trucks are being used by the city in this work. They are the rear dump with bed 11 feet long and 6½ feet wide. By the use of these trucks we save the long team haul, the most important money-saving feature of our entire scheme.

The two new furnaces we have installed have each an auxiliary boiler. These were placed with the idea of allowing the sale of steam. We develop 225 h.p. at each plant, but on account of the drawing of our fires about once in four hours, we find it necessary, in order to guarantee the sale of steam, to install the auxiliary boiler, its furnace to be fed with the same material, i.e., the city's waste.

TABLE OF MINERAL PRODUCTION OF THE PROVINCE OF QUEBEC DURING 1912.

Substances.	Production, 1912. Quantities.	Value.	Value in 1911.
Asbestos, tons	111,175	$ 3,059,084	$3,026,306
Asbestic, tons	25,471	23,358	19,802
Copper and sulphur ore, tons	62,107	631,963	240,097
Gold, ounces	980	19,924	11,800
Silver, ounces	26,526	14,591	11,500

1910	7,323,281
1911	8,679,786
1912	11,017,046

Notes on Mineral Production in 1912.

Asbestos.—Asbestos, as in the past years, heads the list of the products of the Quebec mines in 1912. After having passed through a severe crisis, the asbestos market is steadily improving. This is specially true for the higher grades, crude and long fibre mill-stock. The demand for the short mill-stock is not brisk, and, as a consequence, the qualities under $30 a ton have to be sacrificed to some extent.

Therefore, under these circumstances, of good prices for high-grade stock and low prices for short mill-stock, it is quite easy to understand that only the mines which can produce the better qualities are able to operate satisfactorily. Hence, none of the mines of the Broughton district were operated during 1912, as the Broughton rock is essentially a milling rock, containing as a rule a gool percentage of disseminated fibre, but short and low in value. The same remark applies to most of the mines of the Robertson district.

On the other hand, the Thetford mines and the Black Lake mines worked steadily and the shipments are higher than for 1911.

WATER REQUIREMENTS OF A LARGE RAILWAY SYSTEM.

At the meeting of the Illinois Water Supply Association C. R. Knowles, general foreman of waterworks, read a paper, of which the following is an abstract:—

The consumption of water by railway systems has greatly increased, and it has been necessary to raise the standard of the supply, both in quantity and quality, to meet traffic conditions. In former years it was the practice to erect a tank and establish a water station at any point where water of any kind was most convenient, with little regard to the quality or future requirements. This has necessitated many changes to meet the new conditions and added requirements, such as relocating water stations with due regard to curvature, grades and the many previously unknown expedients of operation.

To accomplish these results it is often necessary to pipe water a considerable distance, or, if an ample supply is not otherwise available, to sink wells or construct a reservoir impounding a storage supply. In the event that the available supply is not satisfactory in quality, it is often necessary to erect treating plants to convert it into a suitable water for locomotive purposes. All these changing conditions and increasing requirements have made it necessary to maintain a waterworks department organization, whose duties are similar to those of a city waterworks department.

The amount of water required for all purposes by one railroad 6,500 miles long is approximately 16,500,000,000 gal. annually. In the State of Illinois, on 2,000 miles of road,

4,236,838,000 gal. of water was used for locomotives alone, of which 1,751,790,000 gal. is purchased from municipal and privately-owned waterworks plants and 138,645,000 gal. is treated by purifying plants owned by the railroad. It is necessary to maintain 123 water stations to distribute this water to locomotives. In addition to the above, the washing and filling of locomotive boilers at terminals requires approximately 950,000,000 gal. per annum, which is provided by the same pumping plants with additional facilities for maintaining the desired pressure for washing the boilers and the necessary pipe line for the distribution of this water under pressure.

Stationary power plants also require approximately 300,000,000 gal. per annum, including water used for condensing engines, of which 125,000,000 gal. is city water. It is estimated that 250,000,000 gal. additional is required for miscellaneous purposes at shops, roundhouses, offices and stations. This makes a grand total of 5,736,838,000 gal. of water used for all purposes by this one road in Illinois alone.

CITY PAVEMENTS.

By C. C. Powell.*

For the benefit of those readers who were not fortunate enough to be able to attend the recently held annual meeting of the Ontario Good Roads Association, we publish the following abstract of the paper presented by Mr. Powell before it.

During my experience in Toronto I have found that the people are, as a whole, greatly interested in the question of pavements, and will generally take the initiative in this matter; in fact, demands for pavements are often made by property owners before the sewers are constructed, and during a period of great real estate activity the requests for pavements of one kind or another are so great as to tax the best efforts of the Works Department to keep up with them.

The pavement work of Toronto is all carried out on the local improvement plan:

1. On petition.
2. On the initiative or without petition.
3. On the initiative by ⅔-vote of council.

1. When a work is undertaken on petition, the requirements are as follows:—A petition form must be obtained from the Works Department giving the description of the street to be paved, width of pavement, cost per foot frontage, annual cost per foot frontage for the life of the pavement, and in order that the people to whom this petition is presented may have an opportunity of knowing the cost of any other pavement, a table of these costs is printed upon the petition form. This precaution is taken so that a person signing a petition can not plead ignorance or misrepresentation in regard to the price to be paid. Such a petition is considered sufficiently signed when it bears the signatures of sixty-six per cent. of the property owners, representing fifty per cent. of the property value.

When a petition is presented and declared to be sufficiently signed a recommendation is made to the council, and if passed by that body the work may be proceeded with.

2. If a work is deemed necessary by the Works Commissioner a recommendation is made on the initiative. When this recommendation passes council, notices are sent to the property owners, and a month is allowed for the owners to petition against the improvement. If no petition is received within this period, the work may be proceeded with. A petition against, to be sufficiently signed, must have the signatures of a majority of the property owners, representing at least half the property value.

3. In cases where trouble is experienced in getting a local improvement laid and where such an improvement is deemed necessary by the Works Commissioner, as being in the public interest, a recommendation is made, and if passed by a two-thirds vote of council the work may be proceeded with, notwithstanding any objections or petition against by the property owners.

With machinery as outlined above, a municipality is well equipped for carrying out any campaign for street improvements that may be decided upon.

The question of the selection of a pavement for a given street is often a difficult one where there are so many kinds to choose from, but, generally speaking, the elements that enter into this selection are:—

1st. Durability, having regard to the traffic to be expected after paving.
2nd. Grade.
3rd. Cleanliness.
4th. Cost.

Permanent pavements are now generally recognized as being best for the more or less heavy traffic to be encountered in a city, and practically no other pavements are being constructed in Toronto. Permanent pavements are generally defined as those baving a concrete foundation, and the practice has been to vary the depth of concrete foundation according to the traffic. These depths vary as follows:—

4" for light traffic..
5" for medium traffic.
6" for heavy traffic.

The so-called permanent pavements are divided as follows:—

1. Sheet pavements.
2. Sectional pavements.
3. Monolithic pavements.

Under sheet pavements are included asphalt, asphaltic concrete, tar concrete, bitulithic, and a number of other patented bituminous pavements.

Sectional pavements comprise brick, stone setts, wooden block and asphalt block.

Monolithic pavements include the various forms of concrete pavements and probably asphalt macadam and tar macadam can be included in this list.

For our guidance in selecting a pavement for a given street, the following table has been made, viz.:—

Up to 3% grade	Any pavement.
From 3% to 5%	Brick, stone sett, asphalt macadam, asphaltic concrete, concrete macadam, rocmac, bitulithic, asphalt block.
From 5% to 7%	Brick, stone sett, macadam, rocmac.
Above 7%	Macadam and rocmac.

For heavy traffic the pavement most in use in Toronto is asphalt, although brick and wooden block have been laid in a number of cases.

The merits of the brick pavement are apparently not very highly appreciated in this city, as almost invariably our recommendations for a pavement of this material are petitioned against, the only reason given being the noise. The repair bill on our brick pavements is much smaller for the same area than for any other pavement.

In the residential districts asphalt, and bitulithic are about the only two pavements laid, although it is expected that asphaltic concrete, asphalt macadam, or rocmac will be laid in increasing quantities as time goes on.

A patented pavement is not recommended unless a sufficiently signed petition has been received asking for such a

*Deputy City Engineer, Toronto, Ont.

pavement. The sheet pavements have reached this popularity for residential streets due largely to their comparative dustlessness and lack of noise.

The standard width of pavement adopted in Toronto for a main thoroughfare, 86-ft. wide, where tracks are laid, is 54-ft. from kerb to kerb, allowing 18-ft. of pavement on either side of the track allowance, or 19' 3" if we include the blocks next the rails. This width provides for two lines of traffic. Where the street is only 66' wide and tracks exist, the standard is 42-ft., giving a pavement 13' 3" on either side of the track allowance, including the blocks next to the rails. On residential streets, the standard width of pavement is 24-ft., although in the past some pavements as narrow as 18-ft. have been constructed. Pavements of greater width than 24-ft. are laid where traffic conditions warrant it. There is now an agitation to have the standard width for residential streets increased to 28-ft. The agitation for this increased width is due to the increase in motor vehicles and the desire of their drivers to be able to pass slow moving vehicles with less inconvenience.

I am of opinion that such a provision is good in so far as the more important thoroughfares are concerned, but it is a hardship to force people to pay for a pavement of greater width than is needed for the traffic of the street, and it will also increase the cost of maintenance materially.

The crown of pavements in a city is also a very important question, and while a high crown tends to increase the life of a pavement by causing the surface water to run quickly to the gutters, it is very hard on horses in frosty weather and in summer time when flushing is being resorted to. This difficulty has become so great during the past year or two that we are now reducing the crown of all new pavements very materially. A few years ago the standard crown for a 24-ft. asphalt pavement was 6". In 1911 this was reduced to 5" and a further reduction to 4" is now contemplated.

Drainage troubles in the construction of city pavements are not very serious, for, as a general rule, the streets are provided with the necessary storm sewers for taking care of the surface water. Catch basins are constructed on opposite sides of the street about every 300-ft., with large openings so that the surface water may quickly reach the sewers. These openings are provided with suitable grates to prevent larger solids from entering the catch basin, and a trap is usually provided to prevent the escape of sewer gas, and also to keep floating rubbish from entering the sewer. In order that the catch basins may be kept clean they are provided with a semi-circular bottom which enables the long scoop to be effectually handled. The main difficulty in connection with surface drainage that has to be contended with in Toronto is getting rid of the water on some of the east and west streets where the grade is practically level. This is usually accomplished by what is termed false grading, that is, the face of the kerb is increased at the catch basin, and decreased at a point some distance away. In this manner five to three inches of additional fall may be secured, which will effectually carry away the water.

One of the most important features of pavement work as carried on by a municipality, is inspection, and as a general thing, great attention is given to both inspection of materials and supervision of the work, to see that the provisions of the specifications are being carried out.

The city of Toronto is provided with a good testing laboratory, in charge of a capable chemist, in which all materials are carefully inspected. Every carload of cement used on city contracts must pass the ordinary seven day test, before used on the work, and if any doubt is aroused as to its soundness, it is held for twenty-eight days. All asphalt, asphaltic mixtures, fluxes, etc., are investigated in the same way, so that the city is reasonably sure of good work, notwithstanding the five year guarantee exacted.

The sand and stone that are used in the manufacture of a pavement must also have careful consideration, and to this end numerous sand and stone gradings have to be made each year to verify the standards laid down in the specification.

The organization in force to look after the actual construction work is as follows: A district superintendent in charge of all contract work in a given district, and under his care sufficient inspectors and time-keepers to take care of every branch of the work. The city also does a good deal of work by day labor.

Probably the feature that gives rise to the greatest amount of controversy between the Engineering Department and the property owners is the question of grade, and the greatest care has to be exercised at all times to see that the grade established on any street does not give rise to claims for damages. Apparently it does not matter whether you cut or fill, the claims for damages appear just the same. Little or no difficulty is experienced in the older parts of the city, but when we start to work on some of the newly annexed portions of the city we are met by conditions that are hard to overcome; buildings have been erected without regard to probable street levels, and as a result the grade has to be mutilated in order to provide proper access to the property.

To overcome this trouble in the future, the department now gives building grades to intending builders and any new streets accepted by the city are only accepted on condition that no claims for damages will be made by reason of the grade established for the roadway.

Instances have occurred in certain parts of the city, where 12 per cent. grades have been established because the cutting or filling necessary would have practically destroyed the adjacent property.

The costs of the various pavements are as follows:—

2" asphalt, 1" binder, 6" concrete	$2.25
2" asphalt, 1" binder, 5" concrete	2.00
2" asphalt, 4" concrete	1.60
2" asphalt, 1" binder (surface only)	1.05
3" asphalt block, 4" concrete	3.45
2" bitulithic, 4" concrete	2.15
2" bitulithic, 5" concrete	2.30
2" bitulithic (surface only)	1.75
Brick on 4" concrete (Canadian)	2.55
Brick on 4" concrete (American)	2.75
Brick on 6" concrete (Canadian)	3.00
Brick on 6" concrete (American)	3.20
Wooden block on 6" concrete	...

The concrete foundation work is composed of:—1 cement; 3 sand; 7 stone.

By instruction from council the Works Commissioner has to submit a tender for all work advertised, with the exception of large bridges and buildings for which special plant is required. As a result the department does a good deal of work by day labor.

In order to carry out this work economically and efficiently, adequate plant and superintendence is necessary. Last year council sanctioned the purchase of a great deal of plant for sewer and roadway construction, which will place the department in good shape to undertake any work of this character that it may be called upon to do. In addition to good plant a force of efficient foremen and superintendents is necessary, and I am glad to say that the city is as well provided with good men to fill these positions as any similar organization anywhere. The day labor work is carried on as a separate branch of the roadway section, with its own superintendents and timekeepers.

The maintenance of city pavements is probably the most important feature, and at the same time the most difficult to properly carry out, but after a good deal of experiment a

scheme has been adopted which will probably give good results. The city is divided into comparatively small sections, and in each one of these sections is located a district foreman who has a store yard, and sufficient men at his disposal to properly patrol the streets and to make the necessary repairs without delay. The additional plant spoken of above will provide us with enough rollers and other plant to do this.

A special feature of this organization is that at definite intervals a report will be made showing the condition of all streets in the city, and will enable the department to plan future work a long way ahead.

One of the most troublesome features of maintenance work is the repair of cuts made for the installation of water services, gas services, and private drains, and apparently in Toronto, nothing has yet been devised to prevent this trouble, although frequent attempts have been made. In some cities legislation has been obtained compelling property owners to have all these services installed before the pavement is laid, but here we have no such law, but are permitted by the Local Improvement Act to recommend both water and sewer services as local improvements, charging back the cost to the property affected. This is not an ideal provision, because property changes hands so frequently and services installed to suit one individual would have to be changed to suit the next, who might desire to arrange his buildings on the lot in a different manner, and, as a consequence, the pavement would have to be cut.

By co-operation with the various public utility corporations it is expected to reduce this cutting to a minimum this year, and it is hoped that all cuts made will be promptly repaired as they will be reported at certain fixed intervals by the patrolmen.

In 1908 the civic asphalt plant was put in operation, and since that time all repairs to pavements out of guarantee, and a good deal of new work has been carried out by the department. Costs have been reduced and a more satisfactory condition of the streets has been maintained. In no time since 1907 has our cost exceeded 77c. per sq. yard..

The city has also a small crushing plant, a No. 4 Austin (Gates) gyratary crusher with a fairly large capacity. This crusher is used to crush old material that comes off the street, and which can be used again as broken stone for concrete in track allowance foundations. This plant enables us to use up material that would otherwise be wasted or remain in the store yards for an indefinite period.

It is also a great convenience in times of shortage of broken stone, for the rubble can be secured and crushed and some of our jobs kept going.

HEATING PIPES UNDER FLOOR.

Heating a building by means of steam pipes embedded in the concrete floor has been successfully accomplished in the chassis testing building of the Moline Automobile Co. at Moline, Ill. The structure is 120 ft. long by 60 ft. wide, with door openings extending completely across the ends of the building.

The workmen are obliged frequently to lie on the floor in making necessary repairs and adjustments, and on this account it was desired to keep the floor surface comfortably warm. To accomplish this, 1¼-in. steam pipes, spaced 42 in. on centres were laid 2 in. below the surface of the 6-in. floor slab. The concrete is reinforced locally against cracking, due to the expansion of the steam pipes, by corrugated, galvanized iron pipes inclosing the former.

Below the floor slab, 8 in. of cinder fill are placed as an insulating material. It is stated that with only five small metal radiators additional, it is possible to obtain a uniform temperature of from 60 to 70 deg. F. throughout the building.

STREET LIGHTING TESTS.

A description of the tests and comparative results obtained from high pressure gas lamps and high candle power arcs was given lately at the Institute of Electrical Engineers, England. The tests were carried on in Manchester, and the paper on these tests by Messrs. S. L. Pearce and H. A. Ratcliff, is given herewith.

Gas Installation in Princess Street.—Four high-pressure lamps were suspended in Princess Street at the same height above the roadway as the arc lamps—namely, 27 ft., 6in. The distance between the lamps varied from 95 ft. 6 in. to 118 ft. 9 in., but 106 ft. 6 in. might be taken as approximately the average.

Each lamp contained three inverted burners, and clear globes were used. At normal pressure each burner was rated at 1,500-candle power, or a total of 4,500-candle power for the complete lamp; but the maximum candle power obtained was only about half this figure.

As originally installed the lamps were fitted with traversing and lowering gears; but these were apparently not successful, as the lamps were at a later date fixed permanently in position. The flexible gas supply tubing was also replaced by rigid galvanized gas barrel.

Princess Street is 60 ft. wide, and as the lamps were, on an average, only 106 ft. 6 in. apart, the resulting illumination was very good, and far superior to any previous example of high-pressure gas lighting in Manchester.

Presumably in order to improve the maximum illuminating effect, but certainly not the uniform distribution of the light, the lamps have been lowered about 1 ft.

Arc Lamps in Portland Street.—The central suspension system was chosen for the lighting of Portland Street, and certain predetermined "units" of light were erected at such calculated distances apart as to give the maximum illumination for the least capital expenditure.

The paper points out that in addition to low initial costs the central lighting system has the following advantages, which appear to outweigh certain known disadvantages:—

(a) The distributing mains can all be kept to one side of the street.

(b) No separate lighting standards are required on the street pavements, with consequent advantage to pedestrian traffic.

(c) A more even illumination is obtained; in other words, the ratio of maximum to minimum illumination is less than with side lighting for a given amount of electrical power employed

The traffic in Portland Street is of a very dense character all day long, and more especially between the hours of 4 p.m. and 6.30, and it was therefore deemed advisable to aim for a high standard of minimum illumination—viz., something of the order of 0.5 foot-candle. The minimum illumination at any point on a horizontal plane at ground level was expected to be not less than 0.44 foot-candle. This figure was not obtained with the lamps as at first installed, but has since been exceeded.

The length of Portland Street is 1,751 ft., and its width 66 ft. Sixteen 550-watt lamps, working four in series on the 200-volt mains, have been erected. Owing to the positions at which certain important side streets intersect the main street, the distance between lamps varies from 114 ft. to 124 ft.

Eight of the sixteen lamps are run on an all-night circuit, and the remaining eight are switched off at 11 p.m. The lamps are so arranged that, when all sixteen are burning, the lighting is balanced across the three-wire distributing mains; but after 11 p.m. the remaining eight lamps are connected to one side of the system only. The lamps are

fixtures, in so far as no provision has been made for lowering or drawing them to the side of the street. All trimming has therefore to be done from a tower wagon. This decision was come to after carefully considering the extra expense and complication involved in arranging for lowering gear, and also with due regard to the type of lamp selected, the hours of burning, and the local conditions.

The first results obtained were not considered altogether satisfactory; the shadows under the lamps, thrown by the ash-trays, were most pronounced, as was also the series of concentric rings on the surface of the roadway. As fitted with clear inner and opalescent outer globes, the lamps gave a minimum candle-power on the 20-degree ray of 2,250. This was substantially lower than the result anticipated.

Photometric tests showed that the polar curve of the lamps with the particular inner and outer globes used did not meet the necessary requirements, and the resulting distribution of the light was very unequal. The shadows and concentric rings were practically eliminated by the use of slightly opalescent outer globes, but the efficiency of the lamps was impaired to a very appreciable extent, and the distribution of light was rather worse than before, the change from the dark zone midway between lamps to the bright zone adjacent to the lamps being very pronounced.

The paper mentioned that all the testing was done in the streets at night with the lamps burning under normal conditions, and consequently the results obtained are directly applicable to the requirements of practical work.

General Comparisons.—The authors proceeded to observe that any comparison of the Portland Street and Princess Street lighting other than on an "equal basis of cost and illumination" required to be very unbiassed, since there was much to be said in favor of both systems.

"The gas lamps give a much steadier light than the arc lamps, although the difference is not very noticeable to a casual observer, or even to a keen observer; but it is very noticeable when making measurements with a flicker photometer. . . . Unfortunately, although the gas lamps give a steadier light, their candle-power varies very considerably from day to day. The candle-power of a particular lamp may fall at least 50 per cent. before the mantles are renewed, unless it is arranged to change only one mantle at a time, thus spreading the complete change over a fairly long period.

"The candle-power of the arc lamps may vary quite appreciably within a few minutes; but provided that the same make of carbons is used, the average candle-power at any particular angle will not change to any extent from day to day if the line voltage is reasonably constant.

"A very important feature directly affecting the comfort of the general public is the absence or otherwise of glare. . . . Obviously the larger the surface of the light source in proportion to the total amount of light emitted the lower the intrinsic brilliancy and the less the effect of glare. In this respect the three-burner high-pressure gas lamps have an advantage over the flame arc lamps with clear inner and outer globes. The use of clear outer globes with flame arc lamps is, in fact, hardly advisable from the point of view of scientific lighting, since any form of lighting which is productive of eyestrain is essentially unscientific, and is certainly unsatisfactory.

"Two noticeable features in Princess Street are the comparative softness of the shadows of objects cast on the ground and the absence of a pronounced dark horizontal zone in line with the reflectors. The first result is, undoubtedly, due in a great measure to the fairly large triple light source, which has the effect of shading off the edges of shadows; and the absence of a dark zone in line with the reflectors is, no doubt, due partly to the fact that the source of light is well below the reflector, and partly to the reflection from the inner surface of the large globes. The shadows [illegible] by the flame arc lamps when burning with clear inner and [illegible] globes are very intense, and there is no appreciable shading [illegible] of the edges; consequently it is possible to confuse shadows with actual objects. The smallness of the light source, or, in other words, the high intrinsic brilliancy, and the fact that the arc is well up under the reflector, is no doubt the cause of the objectionable horizontal dark zone noticeable in cases where reflectors are used."

The Portland Street light is considered by the authors to have a much warmer and more cheerful effect than the comparatively cold light in Princess Street. The actual relative values of the two schemes of lighting is clearly shown by various tables and curves in the paper giving the results of photometric tests and the contour curves showing the portions of the street area within which the illumination on a horizontal plane is equal to or greater than 0.5 foot-candle.

"Purely from the point of view of illuminating effect," the paper adds, "there is much to be said in favor of both systems; but the electric lighting system possesses all the practical advantages, a few of the more important of which are: (a) Lower cost; (b) simplicity of switching operations, and possibility of dispensing with lamplighters; (c) flexibility and ease of erection; (d) lamps not affected by vibration when suspended from traction poles; (e) possibility of reliable check on running costs (i.e., current consumption and carbons); (f) negligible leakage; (g) absence of globe breakages due to heating, &c.

"All the above advantages are absent in the case of the high-pressure gas system, and in contrast may be mentioned the disadvantages incidental to its use: (a) Extensive and highly dangerous leakage of high-pressure gas; (b) the detrimental effect of a foggy or heavily smoke-laden atmosphere on the mantles, resulting in a serious diminution of candle-power just at a time when it is most required; (c) partial and occasionally complete failure in frosty weather."

Conclusions from the Tests.—Messrs. Pearce and Ratcliff expressed the view that the tests referred to in their paper had at least vindicated the lighting of city streets by means of flame arc lamps, not only on the dual basis of equal cost and illumination, but also on the ground of light distribution.

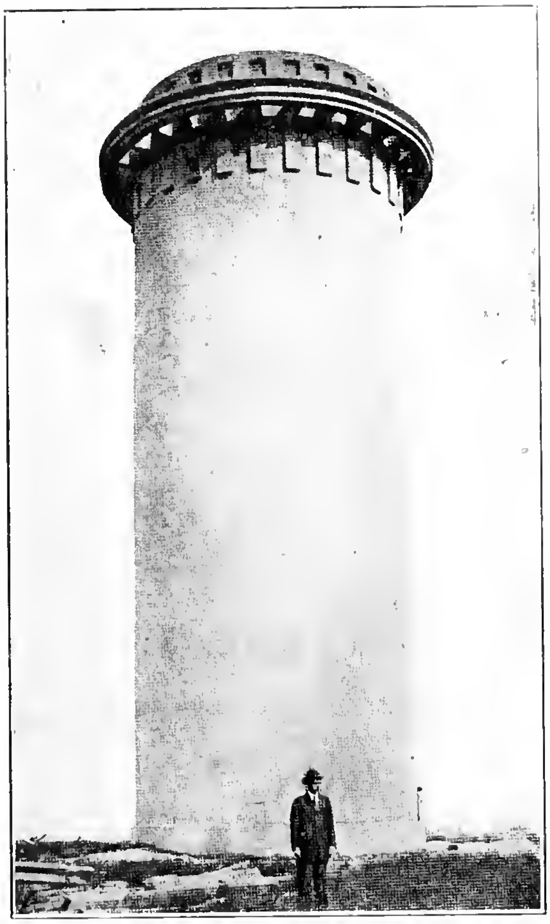
"Unfortunately," they remarked, "owing to many unavoidable difficulties, the experiments with various forms of frosted globes have not yet been quite completed.

As there was a substantial difference between the cost of the flame arcs and the high-pressure gas lamps for the same minimum illumination, it would be possible to improve the arc lighting, if considered desirable, by reducing the distances between lamps in the case of future extensions. If fixed at the present height, and 100 ft. apart, the minimum illumination would be not less than 0.75 foot-candle. No attempt had been made to obtain perfectly uniform illumination, since it was very doubtful whether such a scheme would be desirable, even if possible. A variation factor of 3.75 was not excessive if the change was fairly gradual; and in this respect partially frosted globes gave results quite as favorable as dioptric ones. A well-known authority on street lighting had expressed the opinion that perfectly uniform lighting was flat and uninteresting. From a purely psychological point of view that was no doubt quite correct; but there was probably a more definite psychological explanation. The visual conception of illumination was largely a matter of contrast, in connection with which fatigue of the eye played a very important part. It was therefore quite probable that the hollows in the illumination provided the rest necessary to enable the eye to appreciate the peaks, with the result that the average impression produced was superior to the corresponding effect due to a perfectly uniform system of lighting of equal average intensity.

REINFORCED CONCRETE STANDPIPE.

A standpipe at Belton, Texas, constructed of reinforced concrete, is described by T. L. Fountain, a graduate of Engineering at Cornell University, in the March number of Cornell Civil Engineer.

For many years, the water supply of Belton has been obtained from deep wells, storage and pressure for domestic purposes being secured by use of a steel standpipe located on a hill in the northern part of the city. The pressure thus afforded not being sufficient for satisfactory service to Baylor Female College, located on one of the highest points in the city limits, the height of the standpipe was increased about 30 feet. Several years ago the upper half of this standpipe was torn off by the wind, probably due to the weakness of the plates, which originally were near the top. The pressure and storage afforded by the lower half of the standpipe were so unsatisfactory that a bond issue for extending the mains to the south side of the city and erecting a new standpipe on a hill located there carried without opposition.



Standpipe Complete, Showing Ornamental Cornice and Other Decorative Work at the Top.

The chemical contents of the well water at Belton is such that it rapidly corrodes steel, but has no delterious effect on concrete. The cement mortar coat on the interior of the storage basin at the pumping plant is as sound as when put on 20 years ago, whereas service pipes and fittings all over the city deteriorate rapidly. On this account, estimates for the proposed new standpipe were secured on the basis of using much thicker steel plates than would ordinarily be required. No bids were taken, but the lowest quotation received for a steel standpipe 24 feet in diameter and 75 feet high was over $7,000. At this juncture, the firm of which the writer is a member was employed to prepare plans for the proposed waterworks improvements. Believing that a reinforced concrete standpipe could be constructed at a lower first cost which would last indefinitely without any expense for maintenance or repairs, the design shown in Fig. 1 was submitted to the city, and, upon its approval, work was immediately commenced.

Design.—In the design of this standpipe, certain assumptions were made which resulted in securing its construction at a cost very much less than for a steel standpipe of the same dimensions. However, since its completion, important facts bearing upon the design of the concrete standpipes have been brought out by Mr. Hyram B. Andrews in a paper read by him at a meeting of the Boston Society of Civil Engineers. Had the design been carried out in accordance with his recommendations, the cost would have been nearly as great as for a steel standpipe. A wall thickness of 14 inches was decided upon, as a result of a study of concrete standpipe, previously constructed, this thickness being ample to transmit the stress to the reinforcing steel and to secure imperviousness with the concrete proportions used. The working stress assumed for the steel was 16,000 pounds per square inch. No mechanical bond was used to fasten the bars to each other. They were lapped 36 inches and bound in position with wire. Laps in adjacent rings were not allowed to come in the same vertical line.

When next designing a reinforced standpipe, it is the writer's intention to follow closely the lines laid down by Mr. Andrews in the paper mentioned above, the most important of which are briefly as follows: (1) The use of a very rich mixture of concrete; (2) a thickness of wall sufficient of itself to prevent the rupture of the concrete when the standpipe is full, (3) vertical reinforcement between the base and walls to distribute the bending moment and shearing stress, (4) a steel dam at each horizontal joint, in addition to the usual "keyings" to prevent seepage.

It is of fundamental importance that a standpipe designed and constructed on the assumption that the tensile stress is to be carried by the concrete alone with the reinforcing bars added as a guaranty of safety, should be allowed to stand at least 60 days after completion before being filled so that the concrete can secure its full tensile strength.

The ornamental cornice and other decorative work at the top and base of the standpipe were added to relieve the severe lines of the structure, as the standpipe occupies the crest of the highest hill in the vicinity and can be seen for many miles. As may be seen from the photograph, it has a much more dignified and interesting appearance than a plain cylinder of steel. No manhole is provided in the wall near the base as in a steel standpipe, as the construction difficulties of furnishing such an opening are hard to overcome for a concrete standpipe. The 8-inch inlet pipe is brought up through the bottom for the same reason.

Construction Equipment.—The steel forms for the outside of the standpipe were made from the drawing shown in Fig. 2. Two complete rings were used in order that one might be assembled on top of the other without waiting for the concrete to acquire a hard set and to secure a better bond at the joints by pouring fresh concrete on that still "green." The cost of these forms delivered at Belton was $423.

The concrete was mixed in a 3-cubic-foot batch Smith hand mixer, which discharged into a steel elevator bucket of the same capacity, arranged to run in vertical guides and to dump automatically into a combined bin and chute set above the working platform. The bucket was hoisted by a team, used for other purposes when the pouring was not in progress. The wheelbarrows used in placing the concrete were

filled by opening a wooden gate at the lower end of the bin. The outside scaffolding was made of 3-inch by 10-inch discarded bridge flooring cross braced with 1-inch by 8-inch ship lap. It was erected in sections as the work progressed.

The inside working platform was supported on double rows of 3-inch by 8-inch joists projecting radially from a

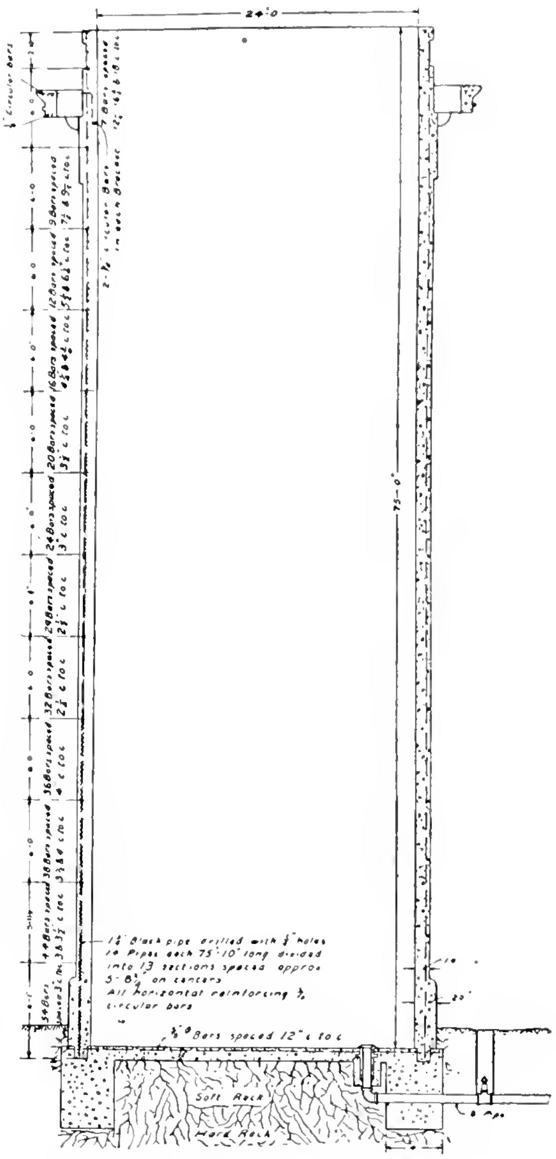


Fig. 1.—Vertical Section of Standpipe.

short central post to which they were rigidly attached. Each pair of floor joists was separated by wooden blocks allowing the 4-inch by 4-inch vertical guide and support studs to pass between them. These studs were set back 2½ feet from the inside of the wall to give room for the wheelbarrows. The only inside flooring was that laid between these studs and the wall. The stud joints were mitered and fastened with bolts. Six feet below the working platform a similar arrangement of joists supported the wooden inside forms, which were made up in sections 6 feet high, or double that of a single set of outside forms. Each of these systems of floor joists was supported by iron pins set in holes bored in the vertical studs at any level required.

Method of Construction.—Excavation for the foundation revealed rather soft rock at the depth originally determined upon for the bottom of the standpipe and wall footings. The excavations for the wall footings was therefore deepened four feet, stopping on solid rock. The concrete for the wall foundation was poured to within about one foot of the lower side of the bottom of the standpipe. The remainder of the wall foundation and the bottom were next placed at one pouring. Keys were left for the walls, as shown in Fig. 1. During this pouring, one-foot lengths of 1¼-inch pipe, threaded on the upper end and provided with sleeves, were set vertically around the periphery in the soft concrete.

The steel forms shown in Fig. 2 were used for the outside of the thicker wall at the base as well as for the remainder of the vertical shell. The increase in the circumference required for the first 6 feet from the bottom was obtained by bolting the plates in each ring against vertical wood spreaders.

The 1¼-inch pipes used for supports for the reinforcing bars came upon the ground cut into sections of the exact length shown in Fig. 1, threaded and drilled. Each 6-foot section was screwed into place as it was reached with the concrete.

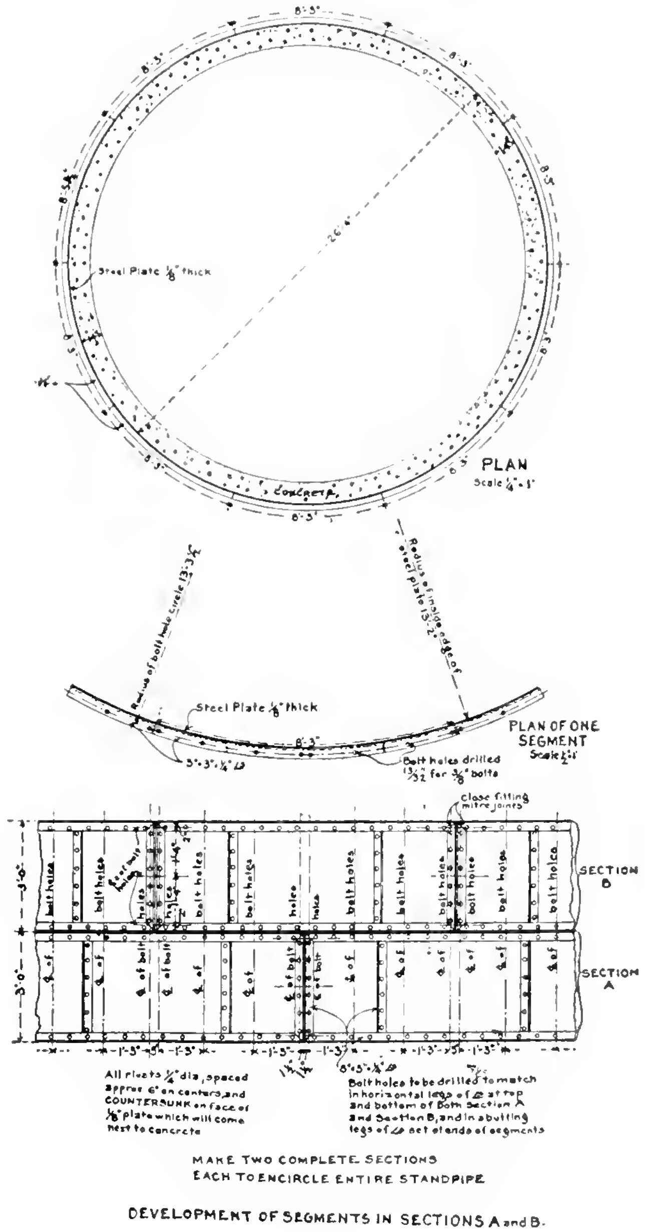

Fig. 2.

The reinforcing bars were bent to the approximate curvature required before hoisting them to position. At each vertical pipe each bar was spaced and held by passing a wire through the ¼-inch holes in the pipe and around the

bar. When the work on the walls was first started, only one three-foot section of concrete could be poured in two days on account of the large amount of reinforcing steel which had to be placed. After a height of 24 feet was reached a three-foot section was poured each day. When the pouring of a secton once started, it was finished regardless of the time required, the work frequently running well into the night on account of the difficulties encountered in raising the inside platform. Each pouring of a three-foot section required about three hours, 9 cubic yards of concrete being placed in that time. The concrete was mixed soft but not sloppy and was distributed in wheelbarrows in layers 12 inches thick, care being taken to equalize the pressure against the forms by uniform distribution. As soon as each pouring of a three-foot section was finished large V-shaped wooden keys were placed in the soft concrete. Before the pouring of another section was begun these keys were removed, the whole exposed surface of the concrete was wire brushed and washed, and the space occupied by the key filled to overflowing with 1:2 mortar.

As soon as the inside forms for each 6-foot section were removed, the inside wall was thoroughly wet and painted with a thick, neat cement grout.

Since the centre of the standpipe was occupied by the joint produced by the abutting radial floor joists, the walls were kept vertical by a centre secured through the use of a 30-inch wooden circular disk the exact size of a circle drawn upon and concentric with the concrete bottom of the standpipe. Three corresponding points 120 degrees apart were set on the disk and circle. The disk was then set in approximate position and adjusted accurately by shifting until plumb bobs dropped from the three points were directly above the corresponding points on the circle below. In order to dampen the plumb bob swing without hiding the three points on the floor circle, glass tumblers filled with water were placed over them.

The entire cornice and brackets are monolithic. The forms for this part of the work were supported on the tops of the outside verticals which were cut off at the proper height for this purpose. The tablets below the cornice were moulded on the ground, hoisted to position, and grouted into recesses left in the wall.

The construction force consisted of 1 foreman, 1 carpenter with 2 helpers, 1 driver with team, and 7 laborers. After the completion of the standpipe the outside was scraped, washed and painted with cement grout mixed with sufficient sand to make it spread readily. When the standpipe was first filled some leakage occurred, due to the development of fine vertical cracks in the concrete as the steel elongated under its working stress. This leakage has gradually decreased, until at present it is an immeasurable quantity. The total cost of the standpipe was $6,000, $500 of which amount was spent upon the cornice and ornamental work.

Concrete.—The gravel and sand used for the concrete occur mixed in the same bank which is located about two miles from the standpipe. The sand varies from rather fine to coarse. In order to secure as dense a concrete as possible for the amount of cement used, sufficient fine sand from a sand pocket in the gravel pit was added to fill the voids in the unscreened mixture of combined gravel and sand. Cement was then added to the proportions of 1 part of cement to 6.33 parts of the aggregate, the entire proportion being as follows: 1 part cement, 2.4 parts coarse sand, 3.6 parts gravel, 0.33 parts fine sand. All gravel and sand particles passing through a ⅜-inch mesh inclined screen were classed as coarse sand. The resulting concrete was very rich in appearance. Cut into some time after the erection of the standpipe, it was found to be hard and dense.

AMERICAN SOCIETY OF CIVIL ENGINEERS TO HOLD SUMMER MEETING AT OTTAWA.

It will doubtless interest a great many of our readers to know that the American Society of Civil Engineers intends to hold their summer convention at Ottawa from June 17th to 20th, inclusive. The headquarters of the convention will be Chateau Laurier. Members of the Canadian Society of Civil Engineers will be delighted to hear of this, and in all probability many of them will take advantage of this opportunity of meeting with fellow-engineers from across the border.

The American Society of Civil Engineers has its headquarters at 220 West 57th Street, New York, the secretary being Charles Warren Hunt, whom, we understand, has held that office since 1895. The society has approximately a total membership of 6,380, of which number about 160 are resident in Canada, located as follows:—

MEMBERS.—Almonte, Ont.—A. Bell. **Amherstburg, Ont.**—C. Y. Dixon, H. Hodgman. **Barrie, Ont.**—F. Moberly. **Brandon, Man.**—R. E. Speakman. **Calgary, Alta.**—H. B. Muckleston. **Chicoutimi, Que.**—J. W. Richardson. **Cochrane, Ont.**—A. T. Tomlinson. **Cornwall, Ont.**—C. D. Sargent. **Dawson, Y.T.**—C. A. Thomas. **Edmonton, Alta.**—J. Callaghan. **Hamilton, Ont.**—J. Hobson, R. M. Roy. **Lachine, Que.**—V. K. Spicer. **Medicine Hat, Alta.**—A. M. Grace. **Moncton, N.B.**—P. S. Archibald. **Montreal, Que.**—W. I. Bishop, W. L. Browne, G. H. Duggan, E. G. Evans, F. E. Field, W. J. Francis, A. S. Going, F. P. Gutelius, G. R. Heckle, H. Holgate, H. S. Holt, J. A. Jamieson, P. Johnson, H. G. Kelley, J. Kennedy, R. B. Kenrick, R. S. Lea, H. M. MacKay, W. McNab, J. Mayer, P. A. Peterson, A. W. Robinson, J. Ross, J. M. Shanly, F. P. Shearwood. **Moose Jaw, Sask.**—L. W. Rundlett. **Nemegos, Ont.**—L. F. The president of the society this year is Geo. F. Swain, Professor of Civil Engineering, Harvard University.

PULVERIZED COAL.

The use of coal that has been pulverized as a fuel, and the economic value of same, is interestingly described in a paper by Mr. H. R. Barnhurst, published in a recent issue of Metallurgical and Chemical Engineering. He states that the requirements necessary to success, while simple, are absolute and must be obeyed.

First—The coal must be dried so that it contains not over 1 per cent. of moisture.

Second—The coal must be pulverized to a high degree of fineness.

Third—It must be projected into a chamber hot enough to cause instant deflagration.

Fourth—It must be supplied with air sufficient to yield the oxygen necessary to burn the carbon of the coal at once to CO_2.

Taking up these requirements in order, the drying of the coal to a moisture content of not over 1 per cent. is indispensable. Coal does not grind well if moisture in excess of this be present.

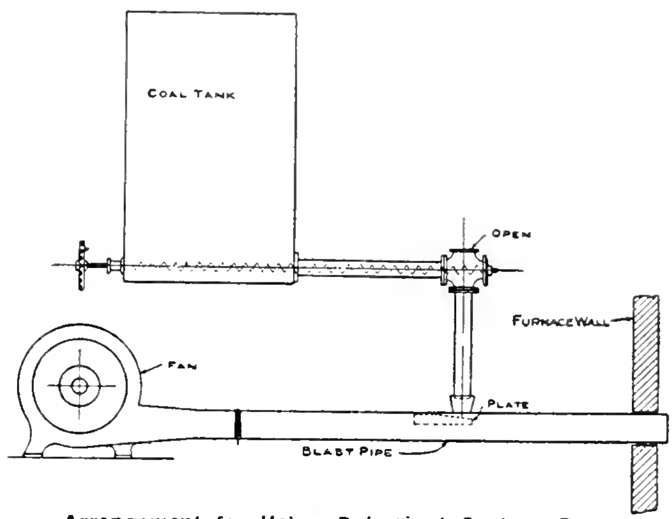
In burning coal the moisture, free or combined, must be disposed of either in the process of preparation or in the moment of combustion. In the latter case not only is the efficiency of the furnace lowered by the calorific investment in the superheated steam passing out as a product, but the temperature of the furnace is lowered materially. The drying of wet coal in the furnace itself, is doing this necessary part of the work in the most expensive place and at the cost of temperatures which may be essential to the industrial process of which high heat is a factor.

Fine grinding—With the best type of machines obtainable for this purpose, the coal and its contained impurities may readily be powdered to such a degree that under the screen tests 85 to 90 per cent. will pass through apertures 1/400 in. square, while the total residuum left upon a screen whose apertures are 1/200 in. square, will be from 2½ to 5 per cent. and this residuum would pass through screens of 1/100 in. square. It must, however, be borne in mind that of the percentage passing the smaller apertures 1/400 in. square there is a high percentage of absolute dust or impalpable powder not commercially measurable. This is proven by the fact that in tests made upon calibrated screens of 1/600 in. square apertures, over 70 per cent. still passed through. It certainly appears to be safe to assume, therefore, that the average size of the particles would be below a cube measuring 1/600 in. on the side.

It may be interesting, therefore, to state that the total numbers of particles resulting from the powdering of 1 cubic inch of coal to the dimensions given would yield 216,000,000 grains of dust. Simple calculation on this basis shows that while a cubic inch of coal exposes 6 square inches for the absorption and liberation of heat, the surface exposed for the same purposes by the powdered coal is 25 square feet. Inasmuch as no fuel burns until it is heated to a temperature at which it developes more heat than it receives, the advantage of this enormous absorbing and delivering surface is apparent. The result of this is shown in the clearness and uniformity of the flame produced. Where coarse particles are permitted to enter the furnace, the distinct sparkles are apparent. These larger particles are carried beyond the region of oxygen supply and are for this reason not fully burned.

Third—While coal ignites freely, in a hot chamber, this ignition means the absorption of heat from somewhere, and if the coal rapidly projected by air does not develop its heat near the point of ignition, means must be devised to maintain the heat necessary for ignition where it is needed, i.e., at the first entrance of the coal into the furnace. It is apparent, therefore, that giving the fuel too great velocity upon entrance is not good practice.

Considering the fourth requirement along with the third we would say that some singular errors and misconceptions have attended the practices of many users of powdered coal. More particularly do we refer to the use of large fans to supply the air necessary for the projection of the fuel, where the air nozzle has been reduced from 16 in. or 18 in. diameter to 4 or 5 in. at the jet under the expectation that all of the air in the 16-in. or 18-in. pipe would be hurried through the 4 or 5-in. nozzle if not a smaller one. The futility of this is apparent.



Arrangement for Using Pulverized Coal as Fuel.

To describe the operation more clearly, the coal is received in a bin over the feeders. (Fig. 1). Its weight is about 38 lb. per cubic foot when loose in the bin. Settling awhile brings the weight to about 45 lb. per cubic foot by displacing the entrained air. Across the bottom of this bin and within a pipe extending horizontally from it is a double-flight worm or feed screw. This double-flight screw resists the tendency of the light coal to flow of itself along the feed pipe. This screw extends over a flanged pipe-cross into which the fuel is delivered. The rear end of the screw is supported by a bearing in a flange on the side of the bin near the bottom, the shaft projecting to receive a driving pulley or chain sprocket. The delivery end of the screw shaft is supported by a bearing in the cover of the horizontal opening of the flanged pipe-cross. The top opening of the cross is uncovered to permit the air to draw down with the falling fuel. This fuel dispersed in the air so drawn in, de-

scends a vertical pipe attached to the lower opening of the cross, the pipe being long enough to be within the funnel or injection pipe. At the bottom of the funnel is a diagonal plate upon which the fuel falls. The plate is tight against the air pipe up the current and flared open on the side, towards the furnace down the current and takes up about one-fourth the diameter of the pipe. This forms at this point a "vena contracta" producing a suction in the funnel, draw-drawing in through it, supplementary air with the fuel. The fuel spraying upon this plate mixes very thoroughly with the air from the fan, the eddy currents caused by it, assisting very materially its dispersal through the main column of air supplied by the fan.

The admission funnel should be far enough from the furnace to permit this mixture to be thorough. Too high pressures defeat this somewhat, as well as tending to project the fuel too far into the furnace before flashing. As soon as this fuel cloud begins to absorb the heat of the chamber into which it passes, a rapid expansion of the air takes place, separating the particles of fuel in suspension, in the proportions of the absolute temperatures to the temperature of the initial air. It is a matter of discussion whether the best results are obtainable by a delivery of all the air found necessary for combustion by the free pipe together with the percentage of excess air found to produce the best results, or to use a smaller quantity of air in the feed pipe and look for the further supply from other openings.

Good practice would seem to point to absolute control of air by the fan and its gates, and the fuel by the varied speed of the feed screw. The furnace should have a good natural draft to a chimney controlled by a damper. It must be remembered that perfect combustion of one pound of carbon demands 2⅔ pounds of oxygen. This is contained in 11.6 pounds of air or about 154 cubic feet; should less than this be supplied a proportionate amount of fuel will be burned to CO with a loss of two-thirds of its initial efficiency, a part of which may be regained by contact with heated oxygen, or it may pass on and burn in the chimney, doing no good if the heated oxygen is brought there in first contact with it. If the oxygen is not heated sufficiently smoke will result and the full heat be undeveloped.

The greater the volatile constituents of the coal the more readily will it deflagrate, as these gases distil from the fuel and ignite at a temperature lower than that required for the carbon itself. Their need for oxygen is, however, greater per pound of fuel (or gases) than that of carbon, and is proportional to the heat evolved. Their average value is in heat units nearly 50 per cent. more than that of carbon.

The temperatures attainable with pulverized coal are very high, so high that excess air is commonly admitted in proportions ranging between 50 and 100 per cent. This will be shown by the following table based upon the perfect theoretical combustion of carbon with proportion of air given:—

1 lb. carbon with 11.6 lb. air...Normal.	4859° F
1 lb. carbon with 12.76 lb. air...10 per cent. excess.	4448° F
1 lb. carbon with 13.92 lb. air...20 per cent. excess.	4102° F.
1 lb. carbon with 15.08 lb. air...30 per cent. excess.	3807° F.
1 lb. carbon with 16.24 lb. air...40 per cent. excess.	3550° F
1 lb. carbon with 17.40 lb. air...50 per cent. excess.	3326° F.
1 lb. carbon with 18.56 lb. air...60 per cent. excess.	3129° F.
1 lb. carbon with 19.72 lb. air...70 per cent. excess.	2954° F
1 lb. carbon with 20.88 lb. air...80 per cent. excess.	2797° F.
1 lb. carbon with 22.04 lb. air...90 per cent. excess.	2656° F.
1 lb. carbon with 23.20 lb. air..100 per cent. excess.	2529° F.

In practice the furnace tender speedily becomes educated to the point of judging whether a fire is hot enough by its color and by the length of the flame. The more perfect the conditions the shorter and whiter the flame will be.

The pulverized coal introduces very effectively the element of time into the equation. Given a pound of fuel with, say 15,000 heat units, these may all be developed by slow combustion at low temperature, or by burning the fuel in pulverized form, quick combustion gives high temperature. The same quantity of heat developed in both cases, but in one instance in a minute and in the other half an hour.

The influence of preheated air upon the economy of the burning of any fuel resolves itself into ascertaining the quantity of fuel which would be necessary to bring the air to the preheated temperature plus the heating of the excess air also to that temperature. Except as a means of transporting heat, excess air has no effect in furnace as far as the fuel combustion is affected. This preheating, to be of any economical value, must be obtained from heat which would else be wasted. To heat all the primary air necessary to combustion and 50 per cent. excess air to a temperature of 1,000 degrees in excess of the surrounding temperatures would show a saving of some 4,100 heat units or nearly 30 per cent. of the fuel value. But few of the industries, however, outside of the metallurgical arts permit the waste heat to pass off at such temperatures and volume as to be available. The regenerative checker-work of open-hearth steel furnaces is the best example of success in this preheating.

In this case it has been a necessity to boost the temperature in this way, because the gases from gas products burned cold, would not give the temperatures necessary for the work to be done.

We may say that four heat units per degree would represent the saving achieved per pound of fuel fired with 50 per cent. excess air by heating all the air admitted to the furnace. The measure of efficiency is dependent upon the loss finally carried away in the rejected gases. In the case of regenerative furnaces this may be lower than in furnaces not equipped with regenerating checker-work, but if to the percentage of loss with regeneratives be added the losses in the gas producers, the pulverized coal directly fired will afford the greater economy of operation.

With the means at hand of obtaining quickly and safely heat of greater intensity than by the use of coal upon grates or in producers, it would appear to render practicable further steps in many of the arts hitherto restricted by the limitations of furnaces at command.

The fear of explosion of coal need not enter into consideration. Coal lying in a bin or conveyer does not explode. It is only when mixed with air or supported by air currents that coal will "puff." In burning it, therefore, we do not mix the coal and air until just as it enters the furnace at high velocity. Against this column of inrushing air and coal the puff cannot take place.

The air is introduced before the coal is turned on, and the coal is shut off before the air. Only by introducing coal faster than it can burn will an explosion occur and then the effect is trifling. It is the gas produced and not the coal that causes this. It wants oxygen and comes outside to get it.

The presence of impurities in the fuel has not much effect. Of course, only combustibles will burn; the incombustibles are inert and do not affect the operation of the furnace. Their effect is in the lessened results from a dollar's worth of fuel negatived by a goodly percentage of waste substance. The writer has burned effectively fuel in which analysis showed 52 per cent. of ash. Let us reiterate the conditions—Dry coal, fine grinding, hot chamber or fire box, proper air supply.

An important part of the subject must not be overlooked. The durability of the future is, of course, vitally essential. In the metallurgical arts when extreme heat is an essential part of the operation, care must be taken to avoid destroying

the furnace by its own operation. This is not difficult. Much of the troubles have come from the gases impinging upon the furnace walls at points where change of direction of gas travel is necessary, and from too high velocity of gases due to contracted ports.

If the utilized heat is largely absorbed from the gases by the charge, the waste gases will be proportionately less active in scouring the brickwork. In almost any construction except perhaps a rotary kiln it is found necessary to change the direction of the gases in their progress toward the flue. This change of direction causes the gases to impunge upon the diverting bricks with an energy proportional to their velocity. The brick at these points can be fully protected by a system of water-cooled pipes embedded in the walls. The brick may frit somewhat until the area of protection is reached, when further progress is arrested.

The surprisingly small amount of water which it has been found necessary to introduce, maintaining the outlet below 200° Fahr. proves that the cooling effect is limited to a prevention of cumulative action and is not perceptibly a drawback upon efficiency. Of course, the piping must be so arranged that no air or steam pockets shall exist and that the circulation will be proportional to the heat stimulus. One other point and we will conclude. The pulverized coal furnace has no ups and downs. There is no thick fire or thin fire, fresh coal or old coal to insure fluctuations.

The furnace can be always kept at its best working point and so kept it will be heated equally all over. Of course, a large charge of metal to be heated will by its very volume absorb heat rapidly, causing a fall in waste gas temperature and possibly a little smoke at first. This is in the nature of things, but the extremely effective conditions quickly bring the charge to a point where the chill is not sufficient to affect combustion and high temperatures come again and smoke disappears. If the work to be done is constant, there is no reason why high conditions may not be uniformly maintained by proper construction and operation.

We believe the subject has been mastered to a point beyond the experimental stage where the full benefits of high efficiency may be confidently relied upon in this beautiful method of burning coal. As before mentioned, the quality of the coal is not with this method of supreme importance. Indeed, its great value in the developments of the future may lie in the efficiencies obtainable from low-class or refractory fuels hitherto unavailable.

PROPOSED POWER PLANTS FOR C.M. AND S.P. RAILWAY.

Details of the proposed electrification of the Chicago, Milwaukee and St. Paul Railroad state that there will be 7 stationary power plants, at least, generating electricity by water-power at Great Falls, Helena, Madison River, Big Hole, and Thompson Falls, near the western border of Montana. All these will be connected in parallel, distributing their power to a single reservoir. Electricity will be conveyed to motors by means of a trolley system. Power will be purchased from the producing company, the railroad having nothing to do with construction and installation of power-plants. St. Paul probably will have 50 electric locomotives to begin the service, specially designed to meet the needs of the situation. These must pull a maximum freight tonnage of 2,100 tons up a 1 per cent. grade. On heavy grades helpers will be added. The locomotives will be limited in design to a speed of 30 miles per hour up grade and 25 miles per hour down grade for passenger motors, and 15 miles per hour for freights.

POLARIS OR NORTH STAR.

By E. S. M. Lovelace, M.Can.Soc.C.E.*

To find the azimuth or true astronomical bearing of a line from an observation taken at any time that the above star happens to be visible.

While the data for an observation to determine the true or astronomical bearing of a line can, of course, always be obtained from one of the almanacs published yearly in this and other countries, yet, to apply the methods therein outlined requires at least some knowledge of field astronomy, and unfortunately, as it happens, numerous engineers, having become rusty on the subejct, have neither the time nor the opportunity to go into the matter when suddenly (as it well may) arises the necessity for making such a determination. Possibly, too, at the particular time an almanac may be not available.

For such, therefore, the following short tables, compiled by the writer in connection with his private practice, and requiring as they do for their application, no previous knowledge of astronomical problems whatever, afford an easy method of making a determination. The principal advantage obtained from the use of the tables (as illustrated by the example given below) is that in place of having to sit up to some inconvenient hour, (waiting, say, for the greatest elongation of the polar star) only, as frequently happens, to find that at the particular moment nothing can be seen, the observation may be made at any convenient time that the star happens to be visible. This is an advantage that at least the men at the instrument will appreciate.

The tables are worked out for the next four years and cover the northern latitudes between 40 and 52 degrees.

Standard time is the local mean time at certain standard meridians west of Greenwich; these standard meridians of longitude corresponding to the various standard times in use in Canada are given in Table III.

t, the hour angle of north star at time of observation T is given by

$$t = T + \Delta T + \Delta' \qquad (1)$$

where T is the standard time of the observation

where ΔT is the correction (four minutes per degree) for difference in longitude between the place of observation and the standard meridian to which T is referred.

where $\Delta' = 3.94$ (D-E) minutes

D being the given date and time of observation expressed decimally to the nearest tenth of a day and E is the constant for the year given in Table I.

Knowing the (approximate) latitude of the place of observation and t, then A the azimuth of north star at time of observation T is given by

$$A = \pm F, \text{ a minutes} \qquad (2)$$

where F and a respectively are interpolated from Tables I. and II., the + sign indicating that the north star is east of true north, the — sign indicating that the north star is west of true north.

T, standard time shown by watch, need only be within three or four minutes of being correct.

ΔT is the correction to the standard time in order to reduce it to local time, this correction corresponding to the difference in longitude between the meridian of the place of observation and the meridian to which the particular standard time shown by the watch is referred. Knowing, therefore, the standard time (whether Atlantic, Eastern, etc.) which the watch is showing, in order to

* Civil and Consulting Engineer, Montreal.

get the correction ΔT it is only necessary to take the difference in degrees between the corresponding longitude given in Table III. and the longitude (approximate only) at the place of observation, for this difference in degrees multiplied by four gives the correction ΔT in minutes.

The correction ΔT is, of course, to be added when the place of observation is to the east of one of the above standard meridians and subtracted when it is to the west of such standard meridian.

In getting $\Delta' = 3.94$ (D-E) minutes, it should be remembered that the astronomical day begins at noon and the hours are numbered consecutively from 0 to 24, while the civil day begins at midnight and the hours are numbered from 0 to 12 a.m. then repeated p.m., thus, civil time August 7th 3h a.m. equals astronomical time August 6th, 15h and D would therefore be August 6.6. In the p.m. hours the dates agree.

Table I.

10 "	—47 "	23 "	+25 "
11 "	—24 "	24 "	+ 0 "
12 "	— 0 "		

Table III.

Standard Time.	Longitude West of Greenwich.
Atlantic standard	60°
Eastern standard	75°
Central standard	90°
Mountain standard	105°
Pacific standard	120°

Example.—Suppose an observation is to be made at Baie St. Paul, County of Charlevoix, Province of Quebec, in 1913. By inspection of a map it can be seen that approximately the latitude of this place is 47° 30′ and the longitude 70° 30′. Say, on August 7th at 8h 22m p.m., eastern standard time, an observation of Polaris is taken: The correction corresponding to one degree of longitude is four minutes.

$\therefore \Delta T = (75° - 70\tfrac{1}{2}°)\ 4 = +\ 18$ minutes

D = August 7.3 and from Table I., E = April 14.0

$\therefore \Delta' = 3.94$ (difference in days between August 7.3 and April 14.0) $= 3.94 \times 115.3 = 454^m = 7^h\ 34^m$

By (1) $t = T + \Delta T + \Delta' =$ 8h 22m + 0h 18m + 7h 34m = 16h 14m.

Interpolating from Tables I. and II.

F corresponding to latitude 47° 30′ is 1.08

a corresponding to hour angle 16h 14m is +84′

$\therefore$ azimuth of Polaris at 8h 22m p.m. is from (2)

$$A = F \times a = 1.08 \times 84 = +\ 91' = 1°\ 31'$$

That is, at 8h 22m p.m. on August 7th, 1913, the Pole star will be 1° 31′ to the east of the true or astronomical north, and from this the true bearing can be ascertained of any line taken in connection with the observation of the star.

GASKETS AND STEAM.

One could easily write fifty-seven varieties of sermons about gaskets, poor packing, and the steam waste incident thereto, but this is not to be one of the regular fifty-seven varieties; it is to be a new and different one. There is many an instance when emergency, and a species of genius, have led a man, back in the woods, into taking his shirt-tail to make a gasket for a cylinder-head. And while this is often a poor and reckless makeshift, it is really better in effect than are some of the uses of thick gaskets where men think they have prepared and are doing the right thing. In the modern steam-engine the clearance space at the ends of the cylinder has been reduced to a point of small fractions, and even the added fraction of an unnecessarily thick gasket may cause useless waste of steam. Some of the old-style engines may be found yet in the rural districts that will show a clearance of an inch between the cylinder-head and the piston at the end of the stroke. And, strange to say, with this staring them in the face, it seems difficult for some to understand why a new engine of the same size will do more work and use less steam when the general construction is the same. In other words, there are some who do not seem to have realized that it takes steam to fill extra space in a cylinder, just the same as it takes steam to drive the engine—and it's the same kind of steam, too. To the class who are thus thick-headed belongs the engineer who puts gaskets an eighth of an inch thick under the cylinder-head simply because he has material of that kind in stock. He might better emulate the back-woodsman in emergencies and use a piece of his shirt-tail. Fortunately, there are not many of this class, even in the backwoods, but as long as the few remain it is in order to point out that all unnecessary space at the end of a steam cylinder calls for the expenditure of unnecessary steam power.—J. Crow Taylor in The National Engineer.

Greater Montreal will erect during the present year forty million dollars' worth of buildings according to the estimate of Mr. R. L. Wherry, secretary of the Builders' Exchange. Last year the figures were $33,080,000.

The Russian Ministry of Ways of Communication has decided to make an investigation in regard to the projected line from Saratov to Novotcherkask. This line would be 400 miles long, would traverse the grain territories of the Don Cossacks territory, and would be of great importance in connection with the future South Siberian Railway, as it would create a direct transit route to the Black Sea for the Siberian agricultural products.

CONTENTS OF THIS ISSUE.

THE STUDY OF STREAM-FLOW DATA.

The increasing utilization of the water-powers of the country emphasize the necessity for the more thorough compilation and recording of stream-flow records.

It is a fact that the engineering schools in Canada, and also in the United States, have not devoted as much attention to this branch of the profession as the importance of the subject deserves. The elementary principles necessary for the intelligent design of most engineering structures and an introduction to the different basic subjects which lie at the foundation of the several branches are well covered in our technical colleges. This is not true, however, of the courses in hydraulic engineering in at least some of its phases. Professor Mead in a recent paper before the Cornell Society of Civil Engineers, in drawing attention to the above fact, states that experience has demonstrated the fact that more failures have resulted in various projects of hydraulic engineering from a lack of an adequate conception on the part of the designing engineer of the fundamental principles of hydrology, or of the importance of the hydrological factors, than from defects in the design of construction of the various structures involved. In many cases the engineer has not possessed sufficient knowledge to appreciate the necessity for hydrological investigation and study, and very frequently has ignorantly made unwarranted assumptions and neglected any investigation whatsoever, from a lack of such appreciation.

The results of this lack of appreciation are apparent to every engineer who stops to think over the record of past failures, even here in Canada: water-power plants constructed on streams without sufficient available flows, or with such irregular flows as to make the projects entire or practical failures; spillways and gates in dams constructed with inadequate capacities for the passage of extreme floods; pumping stations constructed to utilize supplies of water which are too limited for the purpose for which they were intended, or with supplies polluted or otherwise undesirable; industries built in locations subject to serious overflow and unnecessary land damage; protecting works built with no adequate idea of the maximum necessities of the case or their effect on flood heights. While in a few isolated cases failures have been due to the fact that adequate stream flow records have been impossible to obtain, and the engineer, relying on his judgment, has been in error, in most cases the failures are due to an absolute lack of knowledge of hydrological principles.

The fundamental cause for this neglect in analyzing the conditions on which every sound hydraulic project must rest is due in great part to the lack of training in our engineering colleges. This same lack of training is apparent in other parts of the hydraulic engineering courses.

The use of electric power generated from waterfalls has increased, because it has been possible to develop and compete with electric power developed by steam. To compete successfully with the steam engine it is necessary that there should be close speed regulation of hydro-electric plants. This has been easy to secure in past developments, due to the fact that the easier types of plants have been installed first; that is, plants with open canal or short penstock. With the increase in the length of penstocks and the use of long feeder conduits, speed regulation becomes an important factor. Yet to-day very few, if any, of our engineering colleges are giving any training along this line, or are even drawing attention to the necessity for study of such conditions. As a result, plants are being installed which, from the standpoint of regulation, are failures.

The colleges must soon realize their responsibility to the hydraulic engineering student. Courses must be remodelled to give the needed instruction if the list of failures in hydraulic design is to be curtailed.

PUBLIC CARRIERS versus THE PUBLIC.

Paralleling the rapid growth of the cities of this continent, in population and suburban area, are the steady and popular demands of civic governments upon city tramway companies for extension of lines, new methods of business, and increased rolling stock. There is no doubt or question of the necessity and need of this twin growth of tramway accommodation, on either the tramway's part or the civic, but there is almost invariably a considerable difference of opinion about the effectiveness and sufficiency of the means adopted by the street railways to keep abreast of the times. It has resulted in considerable antagonism on the part of the people, upon any refusal of public carriers to carry out improvements, especially if the carriers appear to be making money and growing rich. Many people, while believing in the efficiency of company management, and preferring it if the companies can be prevented from waxing unduly rich, yet do not know how they are to be checked from so becoming, and are ready to threaten them with non-extension of franchise in the meantime. Street railways, with their usual comparatively short franchises, are particularly subject to the people, and one would expect would be likely to quickly carry into effect any reasonable civic wishes which did not entirely besmirch their financial horizon.

It seems "riches" and "what is a fair profit" are relative terms, depending on individualism. There have been protestations on the part of public carriers that they were being unjustly adjudged of their wealth and unfairly pressed by the public to the point where they would have to cease doing business. This is of special interest to the engineer, not only in a general way, but because it may open up a new field whereby boards composed of either high-class financial engineers, or possibly engineers and financiers, will be called in to adjudicate between the people and public carriers as to "what are fair demands" to be made upon the latter.

The first big step in this direction is seen in the bill passed in March by the United States Government, whereby a gigantic investigation of the valuation of the property of common carriers and the securing of information concerning their claims, bonds and other securities, has been set on foot. The Interstate Commerce Commission, which has charge, may appreciate the situation and create (it has been recommended to do so) a board composed of nine members, three to be selected by the Interstate Commerce Commission, three by the American Railway Association, and one each by the army, the navy and the American Society of Civil Engineers. This would provide for a non-partisan, impartial and authoritative body, the conclusions of which would be final.

The immediate effect upon the carriers will be the preparation of a complete valuation of all railroad property, entailing an expense of $3,000,000 to $5,000,000 to the carriers alone. After the railways submit the data it will be necessary for the Interstate Commerce Commission, through its experts and assistants, to prepare valuations, and this will cost the government at least $3,000,000 more.

The law provides that the Commission shall make an inventory and classify the physical property as follows: (a) The original cost to date; (b) the cost of reproduction (new); (c) the cost of reproduction less depreciation, and (d) other values and elements of value.

It is not apparent how the Commission will arrive at the original cost to date of railroads which have no records extending back to the origin of the property, and this will be found to be the case with nearly all roads or parts of roads constructed twenty-five years or more ago. The original cost to date is now available from the balance sheet of any railway company under the head of "Cost of Road and Equipment." It will cost the railroads and the government perhaps $2,000,000 to ascertain the original cost to date by the laborious method of investigating original records, and the result may be no more accurate and reliable than the information already at hand.

The United States engineering opinion of the investigation is that the net result of securing the valuation of railroad property will likely prove that the railroads are not over-capitalized, and that as a whole they are not earning a fair return on their cost and present fair value.

A further and interesting viewpoint of a street railway management's idea of present money-making possibilities is seen in the statement of the vice-persident of the Boston Elevated Railway before the Electric Railway Association. He claimed that if the public were not made to understand and become acquainted with the facts of street railway conditions the companies would not be able to continue to do business. The point to be emphasized was the effect of the demands from the public in the way of extensions of lines, increased transfers, etc. In their case these demands have eaten up the advantages which are supposed to come from doing business for a long time in a growing community. This may be seen from the following data: In 1888 some five or six horse railways were put together, forming a consolidated system, which gave the railway company virtually the monopoly of the business of the city. The operations of this consolidated company began substantially on January 1st, 1888.

In the first year there were gross earnings of $4,276,000, and the capital invested was about 2.72 times the amount of these gross earnings. The average number of revenue passengers for the half trip in that year was 22.5, the average length of the half trip was 3.62 miles, and the average distance from the centre of the city to the ends of the routes was 4.79 miles. Following along from that time there was a constant tendency to extend to the more sparsely settled territory, and the lines afterward were extended, not only as to the trips that were run, but as to the total length of the routes. The company began also immediately to electrify the lines, so that in 1892 about half of the system was electrified and the number of revenue passengers per half trip had gone up from 22.5 to 28. Four years later, in 1896, the road was 98 per cent. electrified, and there were 29.5 revenue passengers to the half trip.

Later, the rapid-transit system—that is, the subways and the elevated—was introduced with a view to providing more room for the congested district, and with these lines the demands that were made for service cut down the average revenue passengers per half trip, so that these figures in 1903 went down to 23, and in 1912 were only 25.5. In other words, in 1912, with gross earnings of $16,644,000, only three more revenue passengers to the half trip than with the horse cars in 1888.

These figures are rather significant; what has happened in Boston is probably typical of what will happen in many cities as business increases. Not only will there be more demands for transfers, more demands for ex-

tension in an unprofitable territory, and more demands for new methods of carrying on the business, but in every way the public may take what would be the only increment of the capital invested. The result in Boston has been that the permanent investment has increased to more than six times the gross revenue. It, therefore, appears extremely difficult to carry on business and satisfactorily meet public demands in the United States.

In Canada conditions between the railways and the public are not exactly similar to those in the United States. Nevertheless, there is a sufficiency of resemblance in the attitude of the public mind to make it well worth our while to note and endeavor to profit by the struggles, successes and failures of our neighbors to the south.

OTTAWA'S WATER SUPPLY.*

Writing in a letter to Mayor Ellis, Dr. C. A. Houston suggests that tests of the water of the Gatineau Lake be made by Mr. Joseph Race, the city bacteriologist. The following is an extract of Dr. Houston's letter: "On the assumption that the lake scheme of supply is provisionally adopted, it will be necessary to carry out the prolonged series of bacteriological, chemical and physical investigations as regards the quality of the water in the lake or lakes likely to be chosen for supply purposes. For the engineering part of the work, Sir Alexander Binnie will, no doubt, send out a competent surveyor; for my part, so far as quality is concerned, I have every confidence in the ability of Mr. Race to carry out the work successfully and to furnish me with such results and reports as will enable me ultimately to pronounce judgment in the matter. The bacteriological side of the question is not so important, as, with the gathering ground freed from all human sources of pollution, there is no possibility of the water conveying disease. Physical and chemical tests, on the other hand, are most important, and the water should also be examined for algæ. It will be necessary to collect samples periodically from the lake or lakes likely to be eventually chosen at various spots, and possibly at different depths, and accurate records must be kept of color, hardness, alkalinity, presence or absence of suspended matter, conditions as regards algal growths, temperatures, presence of iron, etc."

* Dr. Houston and Sir Alexander Binnie, the British experts engaged to report on Ottawa's water supply.

FOREST PROTECTION.

A very important conference upon the matter of forest protection along the lines of operating railways in the West has just closed at Winnipeg, the British Columbia Department of Forestry having been represented by Mr. R. H. Benedict, of the headquarters staff, and the parties to the convention being the federal Board of Railway Commissioners, the Province of British Columbia, the Canadian Pacific, the Grand Trunk Pacific, Canadian Northern and Great Northern Railway Companies. General protection of timber along the rights-of-way was the theme of discussion. Last year every mile of right-of-way was inspected by the provincial officers, and the regulations strictly enforced to guarantee the safety of near forests and due payment of royalty for timber cut on Crown lands. The work of inspection is peculiarly onerous in connection with construction operations, and, on the whole, the provincial officers have been well supported by the railway companies. The rule has been laid down that everything cut without permit is considered to constitute a trespass, and where timber is cut, with or without permit, the brush must be properly disposed of without delay.

EXHAUST STEAM AND ITS UTILIZATION AT COLLIERIES AND MINES.

An interesting paper on the above subject was recently presented by J. M. Gordon, at the annual meeting of the Canadian Mining Institute. In the course of his paper Mr. Gordon stated that up to within comparatively recent years the loss of the exhaust steam, and the amount of live steam that was carried down the mine to haulage engines and pumps received scant attention by mining engineers. There was, until recently, no demand for the small sizes of coal from the dry screening plant, and the silt and sludge from the washery; it was argued, therefore, that it was just as well to burn the small sizes in the boilers, than to dump it in a corner of the colliery yard where it would be in the way and an eyesore. Conditions have now changed. This silt, sludge, culm and buckwheat is no longer valueless. Coking plants, briquetting plants and mechanical stokers must now be fed, while competition and the steady increase in working expenses have made the problem of power distribution in and around mines one of considerable importance. To-day more than ever, the law of the survival of the fittest applies. It is the day of the electrical unit. Thus in many of the more advanced mines in Great Britain and on the Continent, we no longer find those huge old Cornish pumps, grinding and groaning as if in agony; no longer thousands of thermal units going to waste as a result of conducting steam pipes down deep and wet shafts to haulages; no longer long transmission lines of compressed air under ground to distant coal cutters. The day for these has passed. In their place we find high lift centrifugal pumps driven at from 1,500 to 2,000 revolutions per minute; three-phase high-tension armored cables passing down the shaft; and the transformation of the current near the distant coal-cutters to drive an inbye air compressor, or to work the coal-cutters by electricity direct. And this electric power has been generated from the exhaust steam formerly disregarded and wasted.

Meanwhile condensers cannot be used with reciprocating winding engines on account of the difficulty in controlling them; and the compounding of existing reciprocating engines, and the installation of condensing plant gives such a narrow margin of profit with a disproportional increase of worry to the management, together with so heavy an initial expenditure, that it has been found preferable to run these engines non-condensing. But the advent of the exhaust and mixed pressure turbine has made it possible to utilize this hitherto tremendous waste of heat units by converting them into electric units.

Before describing, however, the application and the possibilities of this new power producer, it may be advantageous to first point out the chief differences between the reciprocating engine and the turbine, and to indicate when and how thew should be placed. In the case of the reciprocating engine, the heat units are, by their expansion in a cylinder and change of configuration, made available for useful work through the medium of a fly-wheel; while in a turbine this transformation of static heat energy into kinetic energy may be brought about in one of three different ways: (1) In the impulse turbine by the expansion of the steam in nozzles, impinging on buckets on the periphery of the turbine wheel, which in turn levers the shaft and attains as high a speed in some sizes as 30,000 revolutions per minute: (2) In the reaction turbine, by the alternate passage of the steam through revolving and fixed blades the expansion is performed on both sets of blades, the fixed blades acting as guides; and (3) the operation is performed by means of a combination of the first and the second.

Theoretical thermodynamics teach that when a given quantity of steam at a given pressure and temperature ex-

hausts into a condenser at a certain pressure and corresponding temperature, an equal number of units are available whether a reciprocating engine of a turbine has performed the functions.

The difference lies in the fact that the expansion of steam in a reciprocating engine is controlled by the size of the low pressure cylinder, and the maximum size to which this can be built economically, without undue cylinder condensation and friction, is generally acknowledged to be the equivalent of from 85 per cent. to 88 per cent. of the possible vacuum; while in the case of the turbine the expansion of the steam is only limited by the efficiency of the condensing plant. The higher the vacuum, the greater the efficiency of the turbine; so when purchasing a turbine set, it is absolutely essential to purchase the best condenser on the market.

A glance at the P.V. curve will at once show the greater work-producing capacity of the steam turbine than of the reciprocating engine. The curve shows the adiabatic expansion of unit weight of steam. This curve is theoretical, and only shows the wider limits the turbine can control; and it has nothing whatever to do with the mechanical efficiency of the power producers. The advantage the turbine has lies in its capacity of efficiency utilizing the vacuum.

The advantage of the utilization of this vacuum can be thoroughly appreciated when it is considered that one pound of saturated steam expanded from say 16 lbs. per sq. inch (a little above atmospheric) to 95 per cent. of possible vacuum, that is 0.7 lbs. per sq. inch, generates the same amount of heat units as does the same quantity of superheated steam at 572 F., expanded from 170 pounds per square inch absolute to about atmospheric pressure. Another way of demonstrating the thermo-dynamic advantages of the turbine is by the means of entropy diagram. The first diagram shows a non-condensing engine expanding from the average colliery pressure of 165 pounds per square inch absolute to 29 pounds absolute, and exhausting against a back pressure of 17 pounds absolute. This diagram represents the available energy performed by the non-condensing reciprocating engines at collieries and mines. The second diagram shows the reciprocating engine expanding the steam from 165 pounds absolute down to 10 pounds absolute, and exhausting into a 26-inch vacuum. The third diagram shows the non-condensing engine that performs the work in the first cast, now exhausting into an exhaust steam accumulator and a low pressure turbine utilizing this discarded steam and expanding it from 16 pounds absolute to 28 inches of vacuum.

The increase of available energy demonstrated in the last diagram, makes it so glaringly apparent that further reasoning is not necessary to demonstrate the advantages and economy of the exhaust steam turbine over the reciprocating engine when working with low pressure steam.

On looking at these diagrams the question arises why cannot the exhaust steam which one sees so frequently almost enveloping the whole of a bankhead of a deep mine, be used by a condenser. This problem has taxed the ingenuity of engineers for years, and the difficulties to be surmounted have caused such complications that any available advantages have been more than discounted by the initial expense and trouble in connection with the operation of the prime mover and its auxiliaries. When the extreme duties of a winding-engine winding out of a vertical shaft are realized, it is scarcely surprising that condensers are not in use.

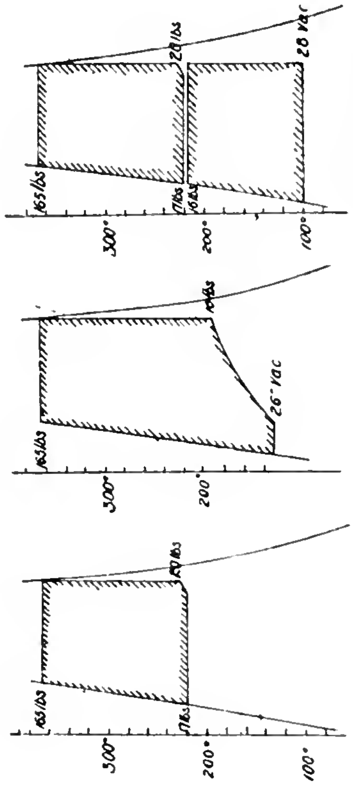
Some of the difficulties to overcome are: fluctuating loads; acute speed variations; reversals of direction of rotation, which have sometimes to take place quickly, and at almost any position of the engine; and, at the most, an average wind of from 20 to 30 seconds. These, then, are the difficulties to be surmounted, and which have baffled engineers for so long, and have resulted in the loss of countless millions of horse-power. The invention of the accumulator by Professor Rateau introduced the low pressure turbine into this field of intermittent steam, with very beneficial results.

Figure 3 is interesting, as it shows the amount of energy available by the adiabatic expansion of one pound of dry saturated steam when expanded from 120 pounds absolute; with the increase 0.5 in. of vacuum, from 27 in. to 29 in., with a barometer at 30 in. Expanded to atmospheric pressure we have 120,000 foot-pounds, and on the continuance of expansion to 1 lb. absolute, or 28 in. of vacuum the number of foot-pounds are almost doubled. In other words, the power available with a low pressure turbine, is increased almost 100 per cent. The utilization of this extra 100 per cent. by such a prime mover working on a 28-in. vacuum, is plotted in Fig. 4. This shows the consumption of steam per kw. hour at full load, with the amount of energy in kw. hours that can be recovered from a given quantity of exhaust steam per hour. On a 750 kw. set, the steam consumption is 36.5 lbs. per kw. hour or 39 lbs. per b.h.p., i.e., for every thousand pounds of exhaust steam per hour, 39 b.h.p. can be regained.

The history of the steam turbine is well known and hence any recapitulation is unnecessary, but it may be mentioned that it was not until the year 1902 that the exhaust steam turbine was introduced, when almost simultaneously engines of this type were patented by the Hon. C. A. Parsons and Prof. Rateau. The first Rateau turbine was installed at the Bonay mines in France.

In applying exhaust steam turbines to reciprocating engines at collieries and mines, there are two distinct propositions to be confronted. First, the case where the supply of exhaust steam is constant, but variable in quantity, and second, where the supply is intermittent and erratic, and where winding engines cease operating at night, but pumping must continue.

The first condition is brought about by fan engines feed pumps, and other auxiliary prime movers. Here a low pressure turbine is applicable, with the addition of a reducing valve, so as to reduce live steam in case of the exhaust steam failing in quantity and thus allowing the output of the turbine to drop below its working demands. This reducing of live steam in a valve before entering an exhaust steam turbine, is anything but economical and cannot be recommended. A turbine known as the mixed-pressure turbine has been devised to utilize this intermittent exhaust steam as well as utilizing live steam in an economical fashion when required to do so. This type of turbine is thus the most adaptable for colliery and mine work. Usually, when the exhaust steam is fairly constant, a receiver, consisting of an old Lancashire boiler-shell, suffices to steady the pressure for all practical purposes; but in extreme cases, and these are the conditions usually encountered at deep mines, it is necessary to resort to the thermal regenerative accumulator through which a comparatively steady supply of steam can be maintained even through the reciprocating engines may be stopped for an interval of five minutes. There are at the present day three or four types of regenerators on the market. Prof. Rateau has the honor of inventing two types of these accumulators, the functions of which are to store up surplus heat supplied when the reciprocating engines are running, and regenerating and delivering when the engines are at rest. These regenerative accumulators to be of a commercial possibility, must be so constructed that they shall have the capacity of storing enough heat units to supply the turbine with exhaust steam, should the exhaust steam be cut off for from, say, three to five minutes. In the scrap



Reciprocating Engine Non-Condensing

Fig. 2.

Mixed Pressure Turbine utilizing Exhaust Steam

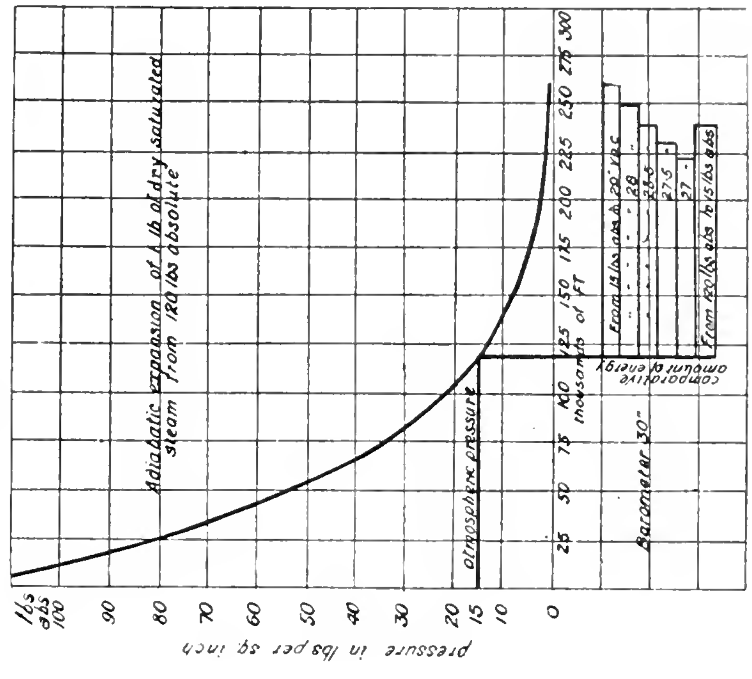

Fig. 3.

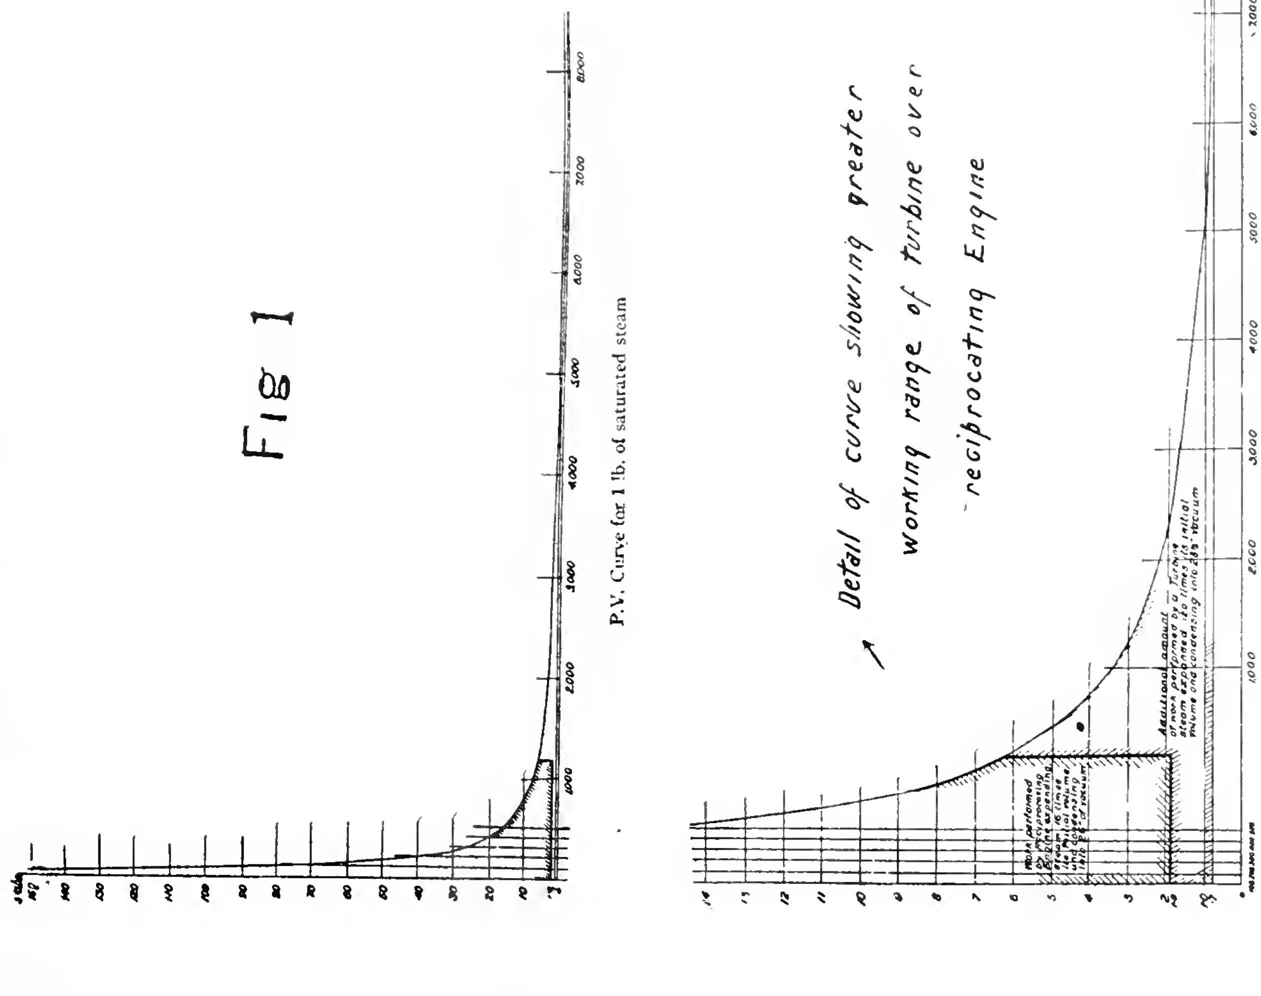


iron type of accumulator, the heat storing medium is scrap iron, which is packed in a loose fashion in an old Lancashire or Cornish boiler-shell. Very little water is required in this type. The exhaust steam condenses in the form of dew on the scrap iron and is re-evaporated when the pressure falls by the heat that is absorbed and retained by the iron. At the Hucknall Torkard Colliery, such an accumulator is in use. It consists of an old boiler-shell, 24 feet long by 6 feet in diameter, contains 50 tons of old rails and scrap iron, and supplies a 175 b.h.p. Rateau turbine during intermittances of 40 seconds. Very few of these accumulators are in use, and there is little likelihood of any further installations of this type on account of their initial cost and tremendous weight. In regenerators of this type, the ratio of the volume of water to iron is as eight to one.

The other type of accumulator invented by Prof. Rateau, is known as the water accumulator. The principle of the Rateau accumulator is to keep steam and water in constant and violent contact with one another in order to raise the temperature of the water to correspond with the pressure, else uncondensed steam would rise and escape through the auto-relief valve. Water in a secondary condition is a bad conductor for the rapid interchange of heat, and the method by which Rateau produced violent circulation in the condensing medium was by utilizing an old boiler-shell or a specially made accumulator shell of about 7 to 8 feet in diameter, the length depending on the capacity of the turbine, while inside the shell are placed longitudinal flues of oval section, with their major axis vertical. The tops of these flues are so placed that the water shall always be a foot above them, the water-level being maintained by a ball float valve. The vertical sides of the flues or tubes are perforated with holes, so that the exhaust steam when delivered into the flues, escapes through the perforations, sends the water into violent circulation, and rises to the surface. A baffle plate is so arranged that it will guide the water back to the bottom of the accumulator, at the same time preventing water from being carried into the turbine, which would be the equivalent of priming in a boiler plant. When the exhaust steam is in excess of the demand, the water is raised to boiling point and then any surplus steam escapes through an auto-relief valve; but when the demand is in excess of the supply the pressure falls inside the regenerator and the water then parts with the heat units it has absorbed by evaporating, thus supplying the turbine with a steady flow of steam and making up for the deficiency. By any chance, should the supply of steam fail, the pressure becomes still further reduced in the accumulator, and the steam in the exhaust pipes becomes liberated to the extent of the weight of the non-return valve, thus keeping the water in agitation, and by the excitation assists evaporation. The back pressure in a 7-ft. to 8-ft. diameter Rateau accumulator is small and is at a minimum when the water is steam saturated; but in the big sizes such at a 12-ft. size, there is a loss of about 3 per cent. for every pound of back pressure. To overcome this, a partition has been introduced dividing the water into two layers, and two sets of steam flues have been provided. The steam spaces about the water are in direct communication, hence the pressure in both compartments is equal.

In practice, the common limits of pressure in these regenerators varies usually from 15 to 18 lbs. per square inch absolute, the difference of temperature being 9.30 F.; that is 103.5 lbs. of water is required for every lb. of steam, since the latent heat of steam at these pressures is 961 B.t.u.'s. This figure in actual practice is raised to 250 lbs. as it is impossible to ensure that the whole of the water in the regenerator will be raised to the highest temperature. The steam is supplied to the turbine through a valve on the top of the regenerator, and here a baffle plate is placed to obstruct any water that may be carried in suspension with the out-going steam. On the inlet steam pipe a non-return valve is usually placed, in order that no water can return to the reciprocating engines when at rest.

In the case of deep mines possessing winding engines having cylinders of from 36 in. to 48 in. diameter and winding from vertical depths of from 2,000 feet to 4,000 feet, it is not only necessary, but economically essential to place some kind of receiver on the exhaust main between the regenerator and the reciprocating engines. This receiver need be only half the size of the accumulator. This assists greatly the regenerative organs of the accumulator, as it steadies the steam flow, acts as a storage cell and greatly assists when the pressure drops in the regenerator. It also has the tendency to prevent the occasional quarter of a pound of extra back pressure on the reciprocating engines when the first few strokes are performed. This receiver can also act as an oil separator, although it is advisable to fit an independent oil separator on the exhaust main. Not only does this oil separator prevent oil from passing through the condenser with the condense water frequently used for feed boiler purposes, but is reclaims a very large percentage of the lubricant oils, in itself an important consideration. A few staggered rows of vertical baffle plates with hollow sides and vertical curves are the essentials constituting this type of oil separator.

Another auxiliary in a turbine set is the condenser, and this will be elaborated on and the balance of article concluded in next week's issue.

CENTRIFUGAL FEED PUMPS FOR BOILERS.

An article on this subject, by Alfred Williams, appears in The Electrical World, in which he says:

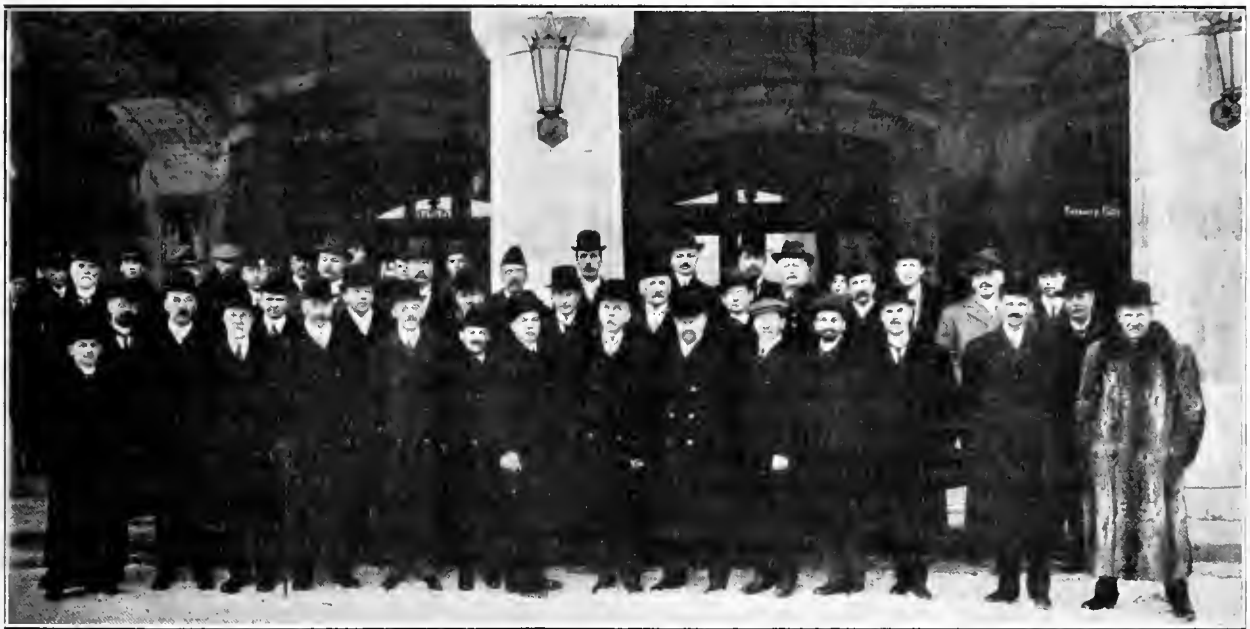
In most of the small central stations throughout the country the time-tried and time-honored simple reciprocating pump for boiler-feed purposes still holds sway, although in newer stations the compound steam-end reciprocating pump is used for the higher boiler pressures employed; but even the latter is fast giving way before the steam-turbine-driven or motor-driven centrifugal pump This change has not been forced owing to any superior economy on the part of the latter unit, but because of its easier operation and lower maintenance cost. There is considerable room for improvement in those stations equipped with the simple reciprocating pumps, especially where the latter call for some 200 to 300 lb. of steam per indicated horse-power. If steam must be used, it would be preferable to employ an independent steam engine which will operate at, say, 60 lb. of steam per indicated horse-power. An argument frequently brought out by persons who oppose the use of electric motors for driving boiler-feed pumps is that the motor does not offer sufficient variation in speed to meet ordinary conditions of practice without introducing resistance in the circuit. It is possible that very much energy might be wasted in this manner, and yet a great saving can be shown over the inefficient direct-acting steam pump. It has been suggested that in place of the single direct-acting steam pump a triplex pump be installed, and that this pump be driven by a constant-speed motor or belted from the main engines. The variations in the rate of pumping can be taken care of by placing a by-pass valve in the suction to the exhaust of one or two of the pump cylinders. Then to vary the rate of pumping it would only be necessary to open the by-pass valve more or less. With the by-pass valve shut the pump works at maximum output. By opening the two by-pass valves wide the rate of pumping in a triplex pump would be reduced two-thirds. Such a pump would be most economically driven from the main engine shaft.

The advantages and economy of using motor-driven or turbine-driven centrifugal pumps for feeding boilers are, however, too great to be ignored.

Among the points in favor of the centrifugal pump are the following: It has neither suction nor discharge valves; it possesses only one moving part which is in continuous rotary motion, and it delivers the water in a constant stream in contrast with the intermittent impulses of the ordinary duplex pump so widely employed for this class of service. Since the stream of water is constant and without impulses, there is no vibration in the pipes, and there is little chance for scale to deposit in them. The pump, moveover, possesses all the advantages of being valveless. There are, therefore, no plungers to be packed, no steam valves to reseat, and no pistons to require new rings from time to time. A feature of the pump which is paramount is that when running at constant speed it delivers water at a certain pressure, which it cannot exceed by more than a few per cent., even though the delivery pipe be completely closed. With the reciprocating pump the latter calamity usually means a broken pipe or pump. This feature of the centrifugal pump makes it possible for a fireman to shut off the feed to any of the boiler or to all of the boilers without shutting off the pump, which in many plants would entail leaving the boilers and going to another part of the station. It is thus possible to feed the boiler automatically by installing a ball-float for each boiler, which would control a balanced valve in the feed pipe. This makes it unnecessary to have connections with a line supplying steam to the pump, as the latter runs continuously whether any of the boilers are being fed or not. This method of automatic feeding makes the boilers independent of each other, and makes it unnecessary for the water line in all the boilers to be at the same level. This latter feature is important in stations containing several sizes of boilers or where some are of the vertical type and some of the horizontal type. It might be contended that the efficiency of a centrifugal pump operating under these circumstances would be very low when supplying only a small portion of its rated output, and that it would consume power when merely turning the water without delivering any. This objection in the case of a motor-driven centrifugal pump is of little moment when its many advantages are considered.—Electrical World.

TWELFTH INTERNATIONAL GEOLOGICAL CONGRESS.

We have at different times referred in *The Canadian Engineer* to the International Geological Congress which is to be held in Toronto during the month of August this year. Through the courtesy of Mr. W. S. Lecky, secretary of the congress, we are pleased to present this week some further facts regarding this congress, also a photograph of the organization committee in connection with it, which held a session in Ottawa on the 4th of March.



Organization Committee, International Geological Congress, to be Held in Toronto August 6th to 14th, 1913.

At that meeting was considered the general arrangements in connection with the programme. On that occasion addresses were delivered by the president, Dr. Adams, on the general objects and work of the International Geological Congress; Dr. W. G. Miller delivered an address regarding the 10th session which was held in Mexico in 1906, and Dr. Coleman, of Toronto, spoke on the 11th session held in Sweden in 1910. Arrangements for the work of the 12th session to be held in Canada this year were described in detail by the General Secretary of the 12th congress, Mr. R. W. Brock.

It is expected that about one thousand delegates will attend the congress, six hundred professional geologists and about four hundred mining engineers, many of them coming from Europe and the United States.

The meetings of the congress will be held in Convocation Hall and lecture rooms of the University of Toronto. The congress will open Wednesday, August 6th, and will continue until Thursday, August 14th, excluding Sunday the 10th.

A series of very interesting excursions have been arranged, and as many of the men who will attend are university professors it is hoped that these excursions, together with the fact that our mines will be generally open to their inspection, the congress will have far-reaching effects.

HIGH-SPEED BEARINGS.

The issue of *The Canadian Engineer* of March 20th, contained a few cuts and an abstract of a paper on "High-Speed Bearings" by J. C. Balfry, read before the Rugby Engineering Society, England. The former article contained a description of the different types of bearings. This week we publish as abstract of the report which deals more particularly with the results and conclusions on the subject.

The total friction work in a particular bearing can be reduced by shortening it. But here one enters dangerous ground, for the manufacturer has to consider much more than frictional losses and the safe running of the machine at normal speeds. He has to think of the stilling of such vibrations as are set up in the shaft when the latter is passing through a critical speed, as well as a possible reduction in oil supply (this depending upon the lubrication arrangements) when the speed of the shaft is declining.

Pressures.—The ordinary pressures to-day are from 50 to 90 lb. per sq. in. of projected bearing surface. In the discussion on a paper read before the American Society of Mechanical Engineers by Professor Christie, it is reported that Professor Hodgkinson remarked that 80 ft. per sec. and 100 lb. per sq. in. were commonly employed, and he saw no reason why these velocities and pressures could not be materially exceeded. This, to some extent, agrees with Lasche's experiments, for within fairly large limits $p \times \mu$ is practically constant.

Velocities.—As already stated, present-day practice with bearings of this kind rules that velocities should not exceed 60 ft. per sec. As μ increases but slightly between 30 ft. per sec. and 80 ft. per sec., there is little fear that a moderate increase on the higher figure will have any ill effect on the bearing, provided that the temperature is not allowed to rise too high and vibration is not forgotten. Allford's work on "Bearings and Their Lubrication" contains a curve showing the relation between pressure and velocity, used by the General Electric Company, of America, for perfect film lubrication. The following are readings taken from the curve:—

V. in Ft./Sec.	p = Lb. per Sq. In.
20	167
30	190
40	208
60	229
73.5	235

From the above it will be noticed that with increase of velocity there is likewise an allowable increase of pressure. Lasche shows that within the limits of his experiments, with v and t constant, the increase of pressure was accomplished by a decrease in μ. Therefore, since $p \times \mu \times v =$ friction work per sq. in. of projected surface, the friction work is affected only by variation in velocity. These deductions are to a certain extent borne out by data taken from the G.E.C. curve.

Many turbine builders assume that for running speeds μ is a constant quantity, and is left out of account in determining the size of a bearing. The determining factors are then the product of pressure and velocity,

$$p \times v \text{ varies from } 2{,}500 \text{ to } 5{,}500;$$

but in the latter product water cooling is resorted to by some builders.

Oiling.—With pressure or pressure-head systems, oil is admitted to a bearing usually either at the sides or at the top. Each system has its advocates, and it is well to remember Beauchamp Tower's classical experiment before attempting to admit oil at other places. Tower showed that the maximum pressure per unit area in the oil film was about twice as great as the calculated mean pressure per unit area on the projected surface of the bearing. Osborne Reynolds has shown, and others have confirmed, that the position of the shaft within the bearing varies with increase of load, and that the point of maximum pressure, which is on the "off" or leaving side, and not on the "on" side, as is sometimes supposed, moves up the "off" side of the bottom half of the bearing and back again to the bottom as the load is increased. For example, imagine that a shaft is rotating in a counterclockwise direction within a bearing, the end view of which is presented towards the reader. The shaft, whose weight compels it to run on the bottom half of the bearing, rotates at first in the lowest position. Using the four cardinal points to simplify matters, the shaft rubs first at S., with increase of load it gradually mounts up to E., dropping to S.E. as the load is still further increased. It is useless, then, to attempt to pump oil between journal and bearing surface anywhere between S. and E. We therefore admit oil at N., W., or S.W., these being the most convenient places.

Professor Goodman has shown that a reduction of the arc of "contact" of the bearing surface on the journal greatly reduces frictional losses in the bearings.

An inspection of Figs. 5 and 7 shows that this fact has been taken advantage of by the reduction of the effective bearing surface on the bottom half by the well-bevelled oil channels at the horizontal centre lines.

The quantity of oil to be delivered to a bearing surface is proportional to its projected area. The following table gives the practice of three leading turbine builders:—

Gallons per Sq. In. per Minute.	Oil Pressure in Lb. per Sq. In.
0.05	45 to 60
0.05	5 to 10
0.01	—

If $p =$ say 60 lb per sq. in. on the projected area;
$\mu =$ coefficient of friction $= 0.025$;
$v =$ velocity in ft. per sec., say 60 ft.;
$p \times \mu \times v =$ work done in ft.-lb. per sq. in. per sec.
$60 \times 0.025 \times 60 \times 60 = 5{,}400$ ft.-lb. per min.

Taking specific heat of oil at 0.4, and sp. gr. as 0.88,
$Q =$ gals. delivered per sq. in. per min. $= 0.45$.
$T_1 =$ temperature of inlet oil, Fahrenheit.
$T_2 =$ temperature of outlet oil, Fahrenheit.
$10 \times 0.88 \times 0.4\,(T_2 - T_1)\,Q =$ B.Th.U. taken up by oil in passing through bearing per pound of oil delivered.

With $T_2 = 130°$ F. and $T_1 = 100°$ F., B.Th.U. per min. capable of being taken up by the oil is $47.5 = 37{,}000$ ft.-lb. per min.

As the journal generates only 5,400 ft.-lb. of friction work per minute per sq. in., we see that there is more than sufficient oil to keep the temperature of the bushes low.

The effect of shaft vibration has to be remembered, and it is more than probable that if this happens to be excessive much more heat is generated through vibration than by friction due to p, μ, and v only.

The selection of a suitable oil is of importance. Great viscosity means loss of power, μ being greater than with small viscosity. Provided that complete lubrication is obtained, the thinnest oil that will do the work will prove the most economical. The following results were obtained on a Sternol patent oil-testing machine at a pressure of 100 lb. per sq. in. at 100 revolutions per min. Duration of test was 55 mins.:—

Oil No.	Relative Friction at Beginning.	Relative Friction at End.	Temp. at Beginning. Deg. F.	Temp. at End. Deg. F.
4	1.45	0.9	68	107
5	2.8	1.25	68	126
6	3.75	1.5	68	132

The curves from which the above were taken fall very gradually.

The effect on the relative coefficient of friction is shown with the temperature rise, the most suitable oil of the three being No. 4, which has the lowest coefficient of friction and lowest temperature rise.

In the following table results of tests on three turbine oils are given; they were obtained with the same machine as were the previous ones at 100 revolutions per min.:—

Oil No.	Relative Friction at Beginning.	Relative Friction at End.	Temp. at Beginning. Deg. F.	Temp. at End. Deg. F.
1	1.8	0.3	86	147
2	5	1.15	86	147
3	6.5	1.25	86	147

No. 1 gives the lowest coefficient of friction at all temperatures from 86° to 147° F. It will be noticed that the oil is colorless, and is therefore as free from impurities as it is possible to get it. The comparative thickness of these last three lubricants at various temperatures is indicated in the third column. According to tests made on the Sternol oil-testing machine, the quantity of oil required varies according to the quality of the lubricant. It is not correct to say that by using a cheaper oil one may use more of it, for if the oil is put on in very large quantities μ is not reduced whatever.

No. 1 oil—Thin, colorless.
No. 2 oil—Green-golden, somewhat heavy.
No. 3 oil—Heavy, golden.
No. 4 oil—Thin, golden.
No. 5 oil—Deep golden, medium.
No. 6 oil—Golden, medium.

In ordinary turbine practice oil is delivered to the bearings at from 100° to 120° F., and returned at from 130° to 150° F.

Radiation.—Lasche has shown that the quantity of heat radiated from a bearing depends upon the extent of the surface exposed to the lower temperature of the surrounding air. Thus a bearing having good metallic contact with a large housing will be able to get rid of a great deal more friction heat than will one that is itself in contact with the cooler surrounding atmosphere.

In Fig. 13 is shown a curve indicating the amount of heat, expressed in foot-pounds, that may be expected to be dissipated into the surrounding air per sec. per sq. in. of projected area.

If Wr = work which bearing can dissipate in foot-pounds per sec. per sq. in. of projected area, t = temperature difference in Fahrenheit degrees, can be closely represented by the equation:

$$Wr = \frac{(t + 31)^2}{3,200}.$$

This may be used when the bearing in question has a relatively thin housing, and is located in still air. If the bearing is situated in a draught—e.g., close to rotating armatures—the right-hand side of the equation may be multiplied by two.

The following table gives the composition of some of the best known anti-friction alloys:—

	Copper.	Lead.	Antimony.	Tin.	Iron.
White metal ...	.....	87.92	12.08	.....	.....
Delta metal ...	92.39	5.1	.....	2.37	0.07
Magnolia metal	.....	83.55	16.45	.....	.....
Babbitt metal .	8.3	.....	8.3	.....	.....

By the use of the "Eatonia" process in the casting of ordinary white-metal linings for bearings, the bearing surface is rendered much more dense, the molecular contraction is much finer, and there is an absence of segregation. Experiments to show the comparison between a bearing lined with white metal, and another of the same size also lined with white metal but "Eatoniaized," indicated that under exactly similar conditions the former seized up when the temperature of the oil-bath rose to 137° F., and the latter showed no signs of seizing up even at 149° F. The pressures were 1,000 lb. per sq in. in each case, oil-bath lubrication was used, and the journal speed was nearly 8 ft. per sec.

Ball Bearings.—A paper bearing our title would hardly be complete without some mention being made of the place that ball bearings are beginning to take in the development of high-speed electrical machinery.

The ball bearing in its various forms has been used with electric generators and motors for some time, not only with light but with heavy machines. Up to the present this form of bearing has not found favor with turbine builders, nor, generally speaking, with generator makers.

It is no doubt due to fear of ball breakage through vibration at the critical speeds of the shafts, and the knowledge of the disastrous consequences which such failure would produce, that turbine makers have not advanced in their adoption of ball bearings. Since ordinary turbine shafts revolve at speeds between 4,000 revolutions per min. and 750 revolutions per min., and weigh from one ton upwards, the weights to be carried at these speeds are consequently high.

It is probable that the first cost, bearing for bearing, is greater in the case of the ball type than with the friction type, but the lubrication arrangements of the former are insignificant when compared with those of the latter. The oil consumption is very small indeed with balls, and the coefficient of friction at starting is about the same as running, this being approximately 0.002 to 0.003. It is recommended that for high-speed ball bearings a somewhat thinner oil be used, and a little more of it than would be necessary with slow-running ball bearings. The oil used should be of a non-corrosive nature and free from impurities, especially those likely to act with the oil and produce results in the same way as fine emery powder or even chalk would be expected to do.

After a bearing suitable to the load, speed, and general conditions has been selected, the three most important points to bear in mind are: (1) Accurate fitting; (2) correct alignment; (3) protection from dirt and moisture.

With most makers the load (corresponding to the speed) on a ball journal bearing suitable for a horizontal shaft may be said to vary inversely as the cube root of the speed, or, expressed in algebraic form:—

$$\text{Safe load} \propto \frac{1}{\sqrt[3]{\text{Revs. per min.}}}$$

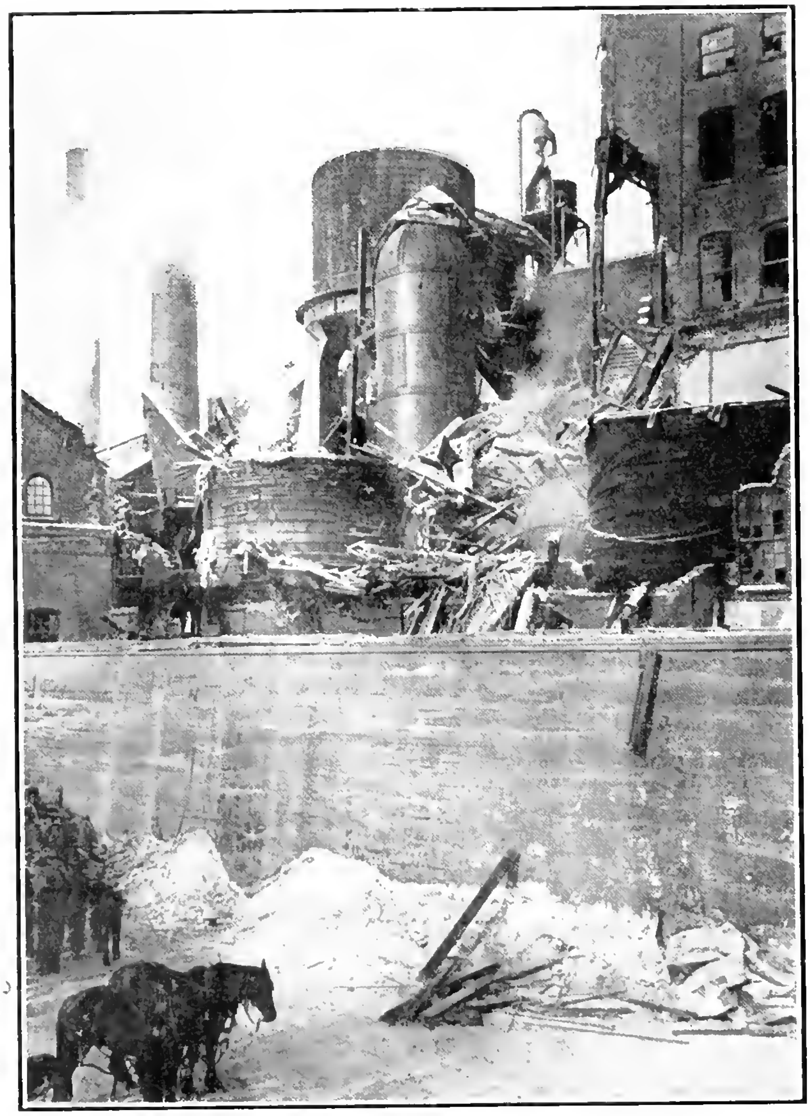
For thrust bearings—

$$\text{Safe load} \propto \frac{1}{\sqrt{\text{Revs. per min.}}}$$

Canadian railroads plan the construction of 2,700 miles of road in 1913, costing $41,000,000, compared with 1,075 in 1912, costing $30,000,000.

SULPHITE DIGESTER EXPLOSION.

The illustration which accompanies this article will give some idea of the tremendous damage done recently at Grand Mere, Quebec, by the explosion of the sulphide digester of the Laurentide Paper Company. A digester is the vessel in which wood is treated with acid in paper manufacture, and is operated at a pressure of 85 to 90 lbs. per square inch. It was 45 feet high by 14 feet diameter. It was built in three courses of three sheets of steel for each course. These steel plates were one inch thick, united by butt joints with single strops of the same material one and one-sixteenth inches thick. The vertical seams were triple rivetted, the girth seams double rivetted. It was lined first with lead about three inches thick, and then with a cement and tile lining about eight inches thick, the object of this lining being to prevent the acid used in cooking the pulpwood coming into contact with the steel sheets of the digester.



Wreckage from Sulphite Digester Explosion.

The vessel had been regularly inspected by inspectors of the Boiler Inspection and Insurance Company, and it is satisfactory to know that the explosion was due to a cause entirely beyond the control of both the owners and the inspecting company.

The initial rupture occurred in the strap on one of the vertical seams in the middle course, which was eight feet six inches in width. The rupture spread along both of the girth straps of this course, which opened up and was torn from the upper and lower portions of the digester. The top portion was blown directly upwards, falling back on the foundation of the digester house, while the lower portion was blown through the south wall of the digester house, falling on and destroying the blow tanks used to receive the cook when emptying the digesters. The middle course was lying on top of the lower portion and was straightened out with the force of the explosion almost flat. There were no tears or ruptures in any of the plates, but that the failure in material was confined solely to the straps, a fact which can be taken to corroborate the opinion subsequently reached as to the cause of the explosion.

The wrecked digester was very carefully and thoroughly examined soon after the explosion, and the conclusion reached was that the explosion was due to a hidden crack in the strap which first failed, and which, starting from the inner surface, gradually worked its way towards the exterior. Its position between the strap and the sheet made it difficult to discover the defect. What supports the conclusion is the fact that of the vertical straps in the same course one showed a crack on its inner surface about two-thirds of its entire length and in a position which a crack of this nature would be expected to occupy. A similar crack was found in one of the vertical straps that had been removed from one of the other digesters.

The expediency of removing the entire lining of a digester at regular intervals and making a thorough internal examination of the shell, is, in spite of the cost of such a step, deserving of serious consideration. It is certain that the cost would be insignificant as compared with the loss that might be avoided. From such an examination only can the strength of the vessel and the pressure at which it is safe to operate it be accurately determined from time to time. In some continental countries such a step at fixed intervals is compulsory by law.

PANAMA CANAL WORK IN JANUARY.

The grand total of canal excavation to February 1 was 190,892,279 cubic yards, leaving to be excavated 27,246,020 cubic yards. Since the last monthly report of excavation was published there have been added to the excavation yet to be accomplished in Culebra Cut 5,634,161 cubic yards on account of the slides that have been developing there. The total excavation for the month of January was 2,612,020 cubic yards. The dry excavation amounted to 1,672,117 cubic yards and was entirely by steamshovels. The dredges and monitors removed 939,903 cubic yards.

In the Atlantic Division, the total excavation was 555,111 cubic yards. Of this total 46,773 cubic yards consisted of dry excavation at Gatun Locks, and the remainder was wet excavation—508,338 cubic yards from the Atlantic entrance.

The total excavation in the Central Division was 1,135,580 cubic yards, which includes 18,360 cubic yards in the Culebra Cut section charged to Obispo Diversion.

In the Pacific Division, the total excavation was 912,329 cubic yards, 489,764 cubic yards of which consisted of dry excavation. Of the 431,565 cubic yards of wet excavation 215,025 cubic yards were from the channel, and 216,540 cubic yards were taken out at the Balboa terminals.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

BOOK REVIEWS:

BOOK REVIEWS.

Elements of Heat-Power Engineering. By C. F. Hirshfeld, M.M.E., and Wm. N. Barnard, M.E. 8 vo., xiii. + 811 pages; 480 figures. Price, $5.00 net. John Wiley and Sons, New York.

Reviewed by A. S. L. Barnes, A,M.I.E.E.*

The authors of this book are professors, respectively, of Power and Steam Engineering at Sibley College, Cornell University, Ithaca, N.Y. As set forth in the preface, an attempt has been made "to include in a single volume not only the elementary thermodynamic theory of gases and vapors and of their cycles, but also the consideration of the sources of heat, the methods of making it available for useful purposes, its utilization in the various types of heat-driven prime movers and their auxiliary apparatus, together with a discussion of the fundamental theory, the ideal and actual performance, and the practical considerations connected with such apparatus."

The book is said to be intended primarily for engineering students, but there is much in it which will be found useful by those who have gone beyond their college days.

The arrangement of this work is very good, being subdivided in such a manner as to make reference to any part a very easy matter; approximately the first half is theory, while the latter half is devoted to descriptions and discussion of various types of steam engines, steam turbines, boilers, gas engines, gas plants, etc.

Although, for many persons, the mathematics in the book will prove somewhat too much, as a knowledge of calculus is presumed, a great deal of useful information may be gleaned from its pages, even by those who cannot follow the equations.

From cover to cover it is evident that the authors have spared no effort to render their work of the greatest value to those for whom it is intended, and the book is worthy of being classed as a standard text book on the subject.

The earlier chapters, commencing with the elementary laws of thermodynamics and of gases, go on to discuss expansions and compressions of the latter, such as take place in all engines using heat as a source of power, curves of entropy changes, various gas cycles, such as the Carnot, Stirling and Ericsson cycles are taken up at considerable length and the advantage of theorizing about ideal conditions is clearly shown in that it enables one to understand what would be the maximum efficiency obtainable under such conditions and in what direction success may be sought.

Later on the properties of steam are dealt with as being the gas in most general use for power purposes; it is comforting here to learn that of the following two formulae the latter is accurate enough for ordinary engineering purposes:

(λ = total heat of steam).

(1) $\lambda = 1150.3 + 0.3745\ (tv - 212) - 0.00055\ (tv - 212)^2$.

(2) $\lambda = 1091.7 + 0.305\ (tv - 32)$.

The latter, it will be noted, is the old Regnault formula with which all steam engineers with any knowledge of theory must be familiar; the first formula is apparently a new one of slightly greater accuracy, developed by Dr. H. N. Davis three or four years ago. The latent heat of vaporization is given in this book as 970 B.th.u. The old value, it will be remembered, was 966.6.

Your practical engineer says that an ounce of practice is worth a pound of theory, but the futility of trying to get along entirely without theory may be well illustrated in the case of a steam engine where it can be proved beforehand that the maximum theoretical efficiency is only some 30 or 40 per cent.; of course, in actual engines it is less still, seldom higher than 25 and sometimes as low as 5 per cent. Theory, in this case, enables one to know what degree of excellence is possible and in what directions lie the greatest hope of success. Without such knowledge in designing "heat-power" plants needless mistakes and disappointments would be inevitable.

In Chapter XV. a good deal of space is allotted to the "Action of Steam in Real Engines," and in Chapter XVI. various methods of decreasing cylinder condensation are discussed. It is herein that one of the fundamental reasons why large engines should be more economical than small ones is pointed out, viz., that in large cylinders the volume enclosed is greater in relation to the radiating surface of the cylinder than in small ones and therefore the cylinder condensation in the former will be relatively less.

Following the above are chapters on various types of steam engines, governors, valve gears, indicator diagrams, etc.

Steam turbines are next dealt with, the ideal turbine coming first, followed by descriptions and drawings of De Laval, Rateau, Zoelly, Curtis, Parsons and other types.

External and internal combustion gas engines succeed the turbines, the former being typified by the various kinds of hot air engines which have from time to time been developed. The chief characteristic of such engines appears to be their extremely low thermal efficiency.

* Hydro-Electric Power Commission.

Internal combustion engines are, of course, very much more satisfactory, and a good deal of space is devoted to them.

The chapters dealing with "Fuels," "Combustion" and "Actual Combustion of Fuels" are very good, and in entire accord with the latest ideas and practice.

Boilers, Superheaters, Draft and Draft Apparatus, Gas Producers and Producer Gas, Feed Water Heaters, Condensers, Water Purification, Power Plants, Air Compressors and Refrigerating Machinery form the subjects of the concluding chapters, after which come problems suitable for students, an appendix containing tables of the properties of saturated and superheated steam, together with a temperature-entropy diagram and a heat-entropy chart.

A copious index brings to a close a book ambitious in its scope, but well carried out, and one which would be very useful to engineers of large electric generating stations and similar plants.

A Textbook of Theodolite Surveying and Levelling.—By James Park, Professor of Mining Engineering in the University of Otago, Dunedin, New Zealand. Published by Charles Griffin & Co., Limited, London. Second edition; 5½ x 8 ins.; 320 pages; 130 illustrations. Price $1.85.

Reviewed by J. B. Harvey, M.Sc.*

This book is intended to be an elementary textbook to cover a two years' course in surveyng. As the title indicates, surveying with the theodolite is dealt with almost exclusively, the author's contention being that at the present time practically all surveying is done with this instrument.

The author's experience seems to have been in the southern hemisphere and more particularly in New Zealand, and, judging from such statements as the following: "The graduated horizontal circle on most theodolites is a frustum of a cone," one must conclude that he is not familiar with the usual style of transit used in Canada.

Chapter I. deals with the care and adjustment of the instrument. Chapter II. is a short one on chains and steel bands. Chapter III. is on obstacles to alignment. Chapters IV. and V. deal with the measurement of angles, traversing and bearings generally. Chapters VI., VII. and VIII. deal with calculations, such as latitudes and departures, omitted lines, areas, etc. Chapter IX. is on the subdivision of land. Chapter X. is on triangulation. Chapter XI. is a long one, covering nearly 100 pages, and deals with astronomical observations. Here, as in other parts of the book, the author makes use of various formulæ, the derivation of which are not given, nor is there any indication as to where one might look for solutions. Chapter XII. deals with levelling, contouring and the bathymetrical survey of lakes. Chapter XIII. is on railway curves. This is after the usual English practice, where the curve is figured from a stated radius and not from some degree of curve, as is our usual practice. Chapter XIV. is a short one on mine surveying.

Except for the fact that some of the terminology does not agree with Canadian practice, and that practically all the numerical examples, especially those in the chapter on astronomy, are from New Zealand, and are thus not always suited to our latitude, the book should make an excellent elementary text. The explanations are usually short and to the point. The text is well supplied with actual problems completely worked out, and also with numerous diagrams and illustrations.

The book might be criticized for having too much space devoted to astronomy.

* Assistant Professor of Surveying and Geodesy, McGill University.

The Effects of Errors in Surveying.—By Henry Briggs, M.Sc., head of the Mining Department in the Heriot Watt College, Edinburgh. Published by Charles Griffin & Co., London. Cloth; size, 5½ x 8 ins.; 179 pages, 22 cuts. Price, $1.25 net.

Reviewed by J. B. Harvey, M.Sc.

"No branch of mathematics is treated in this country (Great Britain) less according to its deserts than that known as the Theory of Probabilities, of which the Theory of Errors is a part." This statement of the author applies about equally well to Canada, and accordingly this book can be recommended to any surveyor or engineer who would like to get some idea of the effect of accidental errors on his surveys.

The author, recognizing the fact that there are many excellent textbooks on the purely mathematical side of the Theory of Errors, devotes the major portion of his book to practical applications of the theory that should be of use to the working surveyor.

Instead of using the Probable Error, or Mean Square Error, as is done in nearly all works on this subject, the author makes use of the Average Error, which he defines as "the arithmetic mean of the separate errors, taken all with the same sign, either plus or minus."

The headings of the various chapters give a fairly clear idea of the matter contained in each: The Analysis of Error, The Propagation of Error in Traversing, The Best Shape of Triangles, The Application of the Methods of Determining Average Error to Certain Problems in Traversing, and The Propagation of Error in Minor Triangulation. The last chapter is a summary of the results obtained in the foregoing chapters, thus providing easy access to the conclusions reached. The book is also well indexed, and contains a number of special tables which would facilitate calculations of this kind.

Only an ordinary knowledge of mathematics is required to read this book. The explanations are well written, and, followed as they usually are by numerical examples, there should be no difficulty in applying the author's conclusions to one's own problems. A great many of the applications given are taken from mining surveys.

The book is not intended for use in high-class Geodetic surveying.

Applied Statics. By Louis A. Martin, Jr., Professor of Mechanics in Stevens Institute. 198 pages. Price, $1.50 net. John Wiley and Sons.

Reviewed by P. Gillespie, B.A.Sc.*

This is the fourth of Professor Martin's series of text books on mechanics, the preceding companion volumes being "Statics," "Kinematics and Kinetics" and "Mechanics of Materials." Typographically and otherwise the make-up of this volume is similar to that of its predecessors. It measures 7½ x 5 inches, and the paper and type are of the usual excellent quality. Many of the illustrations are of structures and machines. These, wisely, are chiefly diagrammatics, showing the mechanical essentials only, and in consequence are not complicated by unnecessary lines. Emphasis through the medium of black letter type is a feature of the text.

The book is intended by the author as an introduction to structural and machine design. It endeavors to encourage the student "to think and not to memorize," and is methodical and progressive in its treatment. Sufficient of the calculus is employed to give to the text a zest for the student who has read the elements of this branch of pure science. In consequence, the book is scarcely in the class usually designated as elementary.

* Associate Professor of Applied Mechanics, University of Toronto.

Not the least commendable feature is the excellent series of problems, numbering upwards of three hundred in all. These continue throughout all chapters and are of such a character that the student is led to realize that the subject he is studying has something beyond a mere academic interest. The book should commend itself to teachers and students.

The New Steam Tables, together with their Derivation and Application.—By C. A. M. Smith, M.Sc., and A. G. Warren, B.Sc., with an Introduction by Sir J. A. Ewing, K.C.B., F.R.S.. Publishers, Constable & Company, Limited, London. Cloth; size, 5½ x 8½ in.; pp. xii. + 101, with Mollier Chart inserted in cover. Price, $1.00 net.

Reviewed by A. R. Roberts.*

The great amount of research work in the last few years on the properties of steam has resulted in modifications of the values determined by Regnault, and made necessary new tables for the convenience of engineers and students.

Several sets of tables, in addition to the one under review, are available at the present time. They are all based on the same experimental work and give practically the same values, but differ in their arrangement and in the method of calculation adopted.

The New Steam Tables are calculated from a series of formulæ deduced by the aid of well-known thermodynamic principles from an empirical characteristic equation connecting the pressure, volume, and temperature of steam. These formulæ are due to H. L. Callendar, F.R.S. The constants in the various formulæ have been adjusted to accord with the latest experimental data. The values of the properties, calculated in this manner, are likely to be more consistent among themselves, though not necessarily in better agreement with the experimental data, than those calculated more directly from empirical formulæ.

A comparison of the values in these tables with those in Marks and Davis' shows considerable differences in many places, particularly in the Latent and Total Heats at high pressures. These differences, however, are of little importance in ordinary engineering work.

The New Steam Tables are arranged in two sets. The first set uses the "Pound-Centigrade" system, which is beginning to find favor with English-speaking engineers; and the second, the "Pound-Fahrenheit" system. In each set are two tables of the usual properties of Saturated Steam, one on a pressure base and the other on a temperature base, and two tables of the Specific Heat of Superheated Steam, one giving instantaneous and the other mean values.

The reviewer is of the opinion that a more complete tabulation of the properties of Superheated Steam would greatly increase the usefulness of the book.

Purification of Water.—By T. Aird Murray, M. Can. Soc. C.E.

A pamphlet containing 36 pages, in which the author presents a number of general principles involved where the purification of water is under consideration. The pamphlet, which is based on a paper read before the annual meeting of the Canadian Public Health Association, Toronto, 1912, describes slow and rapid sand filtration methods, and a very interesting series of tables covering the installation cost of slow sand and mechanical filters in various cities in the United States; also tables showing the operating costs of slow sand and mechanical filter plants.

The pamphlet contains a number of illustrations, together with an extract which appeared in *The Canadian Engineer* of November 9th, 1911, describing the mechanical filtration plant at Saskatoon, Sask. To those who are at all interested in this subject this pamphlet will prove very useful. The author will be glad to supply copies to anyone interested on payment of postage.

*Associate Professor of Mechanical Engineering, McGill University.

Directory of Cement, Gypsum and Lime Manufacturers.—Seventh edition. Leather cover; 2½ x 4 inches; 274 pages. Price, $1.00. Cement Era, 1207 Morton Building, Chicago, Ill.

The purpose of the Directory is, first, to present a complete list of manufacturers, so that any prospective purchaser of these products might locate at a glance any near-by mill. The publishers present in condensed forms lists which are very useful and necessary to the proper conduct of business relating to the manufacturers. It contains a list and location of mills in the United States, Canada and Mexico; alphabetical list of officers, superintendents and chemists of cement companies; list of brands of cement companies; list of gypsum companies; list of lime companies; buyers' guide, statistics on output of Portland cement, gypsum and lime.

Notice.—In the review of Martin's "Design and Construction of Steam Turbines," published on page 380 in the issue of *The Canadian Engineer* of February 27th, 1913, we omitted to state that Messrs. Renouf Publishing Company, Montreal, were the Canadian agents for this book. We would like to take this opportunity of notifying our readers of same.

PUBLICATIONS RECEIVED.

Application for Revision of Toronto Building By-law.—55 pages. Apply to City Architect, Toronto, Ont.

Works Administration.—28 pages.—By Gunn, Richards & Company. H. Victor Brayley, C.E., Canadian manager, Ottawa.

Port of Montreal.—177 pages.—Commercial Review, season of 1912. Published by Gazette Printing Company, Montreal.

Mineral Production of Canada.—Preliminary report for calendar year, 1912. By J. McLeish, B.A., Department of Mines, Ottawa.

Five Thousand Facts About Canada.—By Frank Yeigh. 68 pages. Price, 25 cents. Published by Canadian Facts Publishing Company, 588 Huron Street, Toronto.

Fredericton, N.B.—9 x 6 in.; 60 pages. A well-illustrated description of Fredericton and its advantages. Issued by the Publicity Commissioner, Board of Trade, Fredericton, N.B.

Western Canada Irrigation Association.—Report of the sixth annual Convention, held at Kelowna, B.C. 200 pages: 10 x 7 in. Published by the Department of the Interior, Ottawa.

Railway Routes in Alaska.—Transmitting reports of Alaska Railroad Commission. 170 pages, with maps, etc. Document No. 1346. House of Representatives, Washington, D.C.

Columbia River Power Project, near Dallas, Oregon.—By J. H. Lewis, State Engineer, with Technical Report by L. F. Harza and V. H. Reineking; 56 pages. Bulletin No. 3, Office of State Engineer, Salem, Oregon.

Forest Products of Canada.—Bulletin No. 34, on Lumber, Square Timber, Lath and Shingles; 36 pages. Bulletin No. 35, on Poles and Cross-ties; 18 pages. Both by R. G. Lewis, B.Sc.F. Issued by the Department of the Interior, Ottawa.

Pyrites in Canada.—Its occurrence, exploitation, dressing and uses. By A. W. G. Wilson, Chief of the Metal Mines Division, Ottawa. 200 pages, with maps and illus-

trations. Published by the Department of Mines, Ottawa, Ont.

Data for Use in Designing Culverts and Short-span Bridges.—By Charles H. Moorefield, Highway Engineer, Office of Public Roads; 40 pages. Bulletin No. 45, Office of Public Roads. Issued by the United States Department of Agriculture, Washington, D.C.

Congres Geologique International.—Being second circular issued as regards the International Geological Congress to be held in Canada, 1913. Gives programme and details of arrangements to entertain visitors. Issued by the Secretary, Twelfth International Geological Congress, Victoria Memorial Museum, Ottawa.

CATALOGUES RECEIVED.

Engineering Books.—For 1912. 128 pages. Published by McGraw Hill Book Co., 239 West 39th Street, New York.

The Industrial Building.—Norman A. Hill, supervising engineer and manager. Catalogue of 20 pages of details. Apply 212 Kent Building, Toronto.

Reversible Road Cars for Heavy Freight.—By Buffalo Pitts Company. A handsomely illustrated catalogue 12 x 9 in.; 40 pages. Write Buffalo Pitts Company, Buffalo, N.Y.

Every Man's Encyclopædia.—Twelve volumes of about 640 pages each. Cloth; 7 x 4½ in. Price per volume, cloth, 30 cents; linen-faced cloth, 45 cents; quarter pigskin, 60 cents. J. M. Dent & Sons, Limited, Toronto.

Bridges.—By Ontario Bridge Company. 27 pages; handsomely illustrated with photos, and containing certified letters of work done by different engineers and corporations concerned. Address, main office, Manning Chambers, 72 Queen Street West, Toronto.

Announcement of the Organization of the J. C. White Engineering Corporation and the J. C. White Management Corporation, to assume the functions of J. G. White & Co., Inc. 25 pages of beautifully illustrated and published information. Address, New York.

Chicago Pneumatic Tool Company.—Three catalogues of eight pages each, one being Bulletin No. 129 on Hose, Hose Couplings and Hose Clamp Tools; Bulletin No. 126 on Compression Riveters; Bulletin No. 130, Lubrication of Pneumatic Tools. Canadian offices, the Holden Company, Limited, Montreal, Toronto and Winnipeg.

The Luitwieler System of Water Supply.—Describes the Luitweiler non-pulsating deep well and triplex pumps, hydro-pneumatic system of water supply, elevated tank system, special double service pumps for combination hard and soft water supply, automatic pressure controllers, etc., in an interesting and attractively arranged bulletin. Price lists and full details regarding shipping weight, tank capacities, etc., are appended. A copy of the bulletin will be mailed to any interested person on request. Published by the General Machinery Co., Limited, 22 Mulock Avenue, West Toronto.

SWAN-HUNTER'S BIG SCHEMES.

Presiding at Newcastle, at the annual meeting of Swan, Hunter, Wigham Richardson and Company, the Wallsend shipbuilders, Mr. G. B. Hunter said they were proceeding further in the matter of internal combustion oil engines, and were constructing an interesting vessel to be named "Tynemouth," in which oil would be used to generate power which would be applied to the propelling shaft through electric motors.

COAST TO COAST.

Port Moody, B.C.—The E. J. Dodge Shipping Co., a prominent San Francisco concern, is now in communication with the Vancouver Board of Trade regarding Port Moody's harbor, depth of water and other relative matters with a view to establish the new line of steamships between Port Moody and San Francisco, the cargo coming from the South consisting of cement, and the return fleet bearing large quantities of lumber from the local mills. It is understood that the shipments will be unloaded at Port Moody's newly completed wharf, the only Dominion government wharf on the whole of Burrard Inlet.

Victoria, B.C.—At the present time the forest branch is particularly active in supervising the operation of the railway builders of the 1,890 miles of railway now under construction in British Columbia, every mile of the work now in hand having been gone over during the past few weeks and reports received as to conditions obtaining in the various districts. There are four stages in constructive operations along the railways over which a close supervision is exercised by the forest branch officials. The first is the putting in of the camp and roads. Then comes the stage of right-of-way clearing, followed by that of cutting construction timber and disposing of the slash. In the spring of the year, with the disappearance of the snow, last year's clearings, unless properly attended to at the outset, are likely to constitute a veritable tinder bed.

Washington, D.C.—When the parcels post system had been passed by the legislature the question arose as to the cheapest and most efficient means of delivery of parcels in the big cities. A board of expert engineers was appointed to inspect and report on the many different makes of motor delivery trucks at the recent New York motor show. After a thorough and exhaustive inspection of all the trucks there, they recommended the purchase of Kissel Kar trucks for this purpose, with the result that the United States purchased five Kissel Kar 1,500-pound delivery wagons for the parcels post service of Washington, D.C. These represent the first four wagons of the parcels post service in the United States. If the Kissel Kar reputation is maintained, they are the forerunners of a fleet of Kissel Kars in the service of the United States in all parts of the country.

Regina, Sask.—In view of the fact that there is a great need for additional water supply in the various cities in parts of Southern Saskatchewan, a commission has been appointed for the purpose of investigating the practicability of diverting the water in the Southern Saskatchewan River for domestic and industrial purposes. This commission, which is to be known as the Saskatchewan Water Commission, will be composed of Hon. Senator Ross and A. J. McPherson, chairman of the Highways Commission. The investigation is to be proceeded with as rapidly as possible and consistent with the importance of the project. J. McD. Patton, C.E., who recently resigned the position of superintendent of the city waterworks, is to work in conjunction with the Water Commission, having full charge of the collection of data that is now available in connection with this work.

Victoria, B.C.—Much activity is now going on at Ogden Point, the scene of the new breakwater, which will give Victoria an artificial outer harbor capable of accommodating an enormous fleet of vessels. Heavy blasting is now being done and much rock has been removed by the big charges The contractors will level the land there down to three feet below the roadbed. As the greater part of that section is rock the work will consume some time. Most of the rock will be used in the filling-in work. The contractors who are building the offices for the Dominion inspectors and engineers, Sir John Jackson's employees and various other

offices have almost completed their works and Ogden Point resembles a small settlement. The contractors are greatly favored by having a natural bay close to the Point. The scows are run in at high tide, and as the water recedes they are left high on the sand.

Edmonton, Alta.—Between twenty and thirty elevators will be built, and put into operation by the Alberta Co-Operative Elevator Company, working with government assistance, in time to move the present season's crop.

Toronto, Ont.—The report of Mr. J. F. Whitson, commissioner in charge of the $5,000,000 grant to New Ontario, has been presented to the legislature by Hon. W. H. Hearst. Last year Mr. Whitson spent $208,446 out of the fund and cut or improved 253 miles of road. This year he proposes to spend $1,000,000. Last year the construction was confined entirely to the district of Temiskaming, but work for the current season will be carried out in the districts of Rainy River, Kenora, Thunder Bay, Sudbury, Algoma, and Sault Ste. Marie and Nipissing, as well as an extension of the roads started last year in Temiskaming. Trunk lines are recommended in the Fort William and Port Arthur districts along the lines of the Grand Trunk Pacific and Canadian Pacific Railway, and in the district of Sudbury there will be trunk roads to agricultural and mining sections west and north of the town and north-east through the Wahnapitae Lake district, and a mining road north to the Shining Tree district.

Winnipeg, Man.—The government experiment station at Estevan, for the purpose of demonstrating the commercial possibilities of lignite coal, is now in the initial stages of construction, and it is expected that before many weeks Professor Darling, the leading recognized authority on this mineral in the United States, who has been placed in charge of the investigation by the provincial government, will have proven, through his experimental work, that the extensive coal deposits of the Souris Valley form the most important source of power in the southern portion of the province. The result of the recent exhaustive investigation into this subject, conducted by R. O. Wynne-Roberts, was that lignite coal is now being used extensively in many parts of the world as a fuel and power producer. The matter of installing a gigantic power plant in the near vicinity of Estevan, on the proof of the commercial feasibility of the scheme, is now in the hands of New York financiers, and the money has been found to finance the proposition immediately the tests are completed.

Ottawa, Ont.—That the work of bringing water to Ottawa from the Gatineau Hills will be completed in two years, or in three at the outside, is the statement made by Mayor Ellis. The surveys and preliminary engineering work required for the calling for tenders will be proceeded with at once. Part of this work will be done by the government. The Department of the Interior has never had surveys made of the Gatineau district, though these surveys have to be made sooner or later. Hon. T. W. Crothers, acting Minister of the Interior, stated that the geodetic survey branch of the department will commence its surveys of this district at once. The city is employing a representative of Sir Alexander Binnie & Son's firm, and Mr. J. B. McRae, of Ottawa, to do the required preliminary engineering work, and will also undertake any other survey work which is essential for the proposed water supply, and outside the work of the geodetic survey. It is intended that the geodetic survey should co-operate with those employed by the city. In this way it is expected that the requisite survey and preliminary engineering work will be completed this summer. This becomes possible only through the co-operation of the geodetic survey, so kindly promised by the acting Minister of the Interior. At least a year, and perhaps two, will be gained in this way.

PERSONAL.

MR. J. C. JOHNSTON has been appointed engineer of Port Alberni, B.C.

C. H. TOPP, recently the consulting engineer of Victoria, has been appointed consulting engineer for the municipality of Saanich.

FRANK C. ASKWITH, C.E., who has been acting city engineer since Mr. Ker resigned, has been appointed assistant city engineer of Ottawa.

MR. A. W. DOW, Chemical and Consulting Paving Engineer, New York City, on March 11th delivered an illustrated lecture on the "Manufacture of Wood Paving Blocks," before the graduate students in highway engineering at Columbia University.

MR. NELSON P. LEWIS, M.Am.Soc.C.E., Chief Engineer, Board of Estimate and Apportionment, New York City, on March 13th delivered an illustrated lecture on "Methods of Paying for the Construction of Street Pavements," before the Graduate Students in Highway Engineering at Columbia University.

H. F. McDONALD, B.Sc. (McGill), and C. D. BROWN, B.A. Sc. (Queen's), have opened offices at No. 904 Confederation Life Building, Winnipeg, as consulting engineers and land surveyors. H. F. McDonald has for the past three years held the position of townsite surveyor to the Canadian Pacific Railway. C. D. Brown recently resigned the position of right-of-way surveyor to the same company. Both Mr. McDonald and Mr. Brown hold surveyors' commissions for Manitoba, Saskatchewan and Alberta and intend paying particular attention to subdivisions and town planning in the Western provinces.

OBITUARY.

GEO. H. PEDLAR died suddenly at his home in Oshawa while preparing for a business trip to Chicago. Deceased was president and manager of the Pedlar People, Limited, a company he established over 50 years ago, and which through his ability, became a flourishing concern, having at present offices in Toronto, Montreal, Ottawa, London Chatham, Winnipeg, and Vancouver. He was 70 years of age, and was throughout his busy life actively interested in public and social affairs and a generous giver to all charities.

The Late Geo. H. Pedlar.

CALGARY BRANCH OF THE CANADIAN SOCIETY OF CIVIL ENGINEERS.

At a largely attended meeting of the members of the Canadian Society of Civil Engineers, resident in or near Calgary, held on the evening of the 12th instant, it was resolved to proceed with the organization of a branch in Calgary. Temporary by-laws were adopted, modelled largely on those of the Victoria Branch, and the following officers were appointed to serve until the branch is formally organized, viz.: H. B. Muckleston, chairman; P. M. Sauder, secretary-treasurer; F. H. Peters, A. S. Dawson and E. L. Miles, executive committee. It was decided to secure suitable quarters for a club and reading-room in the near future.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS (TORONTO SECTION).

The fifth regular meeting of the Toronto Section will be held at the Engineers' Club, 96 King Street West, at 8 p.m., on Friday evening, March 28th, 1913. Mr. F. W. Peek, Jr., of the General Electric Company, Schenectady, N.Y., will address the meeting on "High Voltage Engineering." This paper will deal with corona phenomena and insulation problems, as well as transient and voltage control, in connection with long distance high voltage transmission work. No mathematics will be used and the address will be illustrated with stereopticon views.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

The local members of the Canadian Society of Civil Engineers will organize a branch and start a reading and club room in Calgary. The objects of this society are to facilitate the acquirement and interchange of professional knowledge among its members and to encourage original investigation. The membership of the branch will consist of honorary members, members, associate members, juniors, students, and associates of the Canadian Society of Civil Engineers.

COMING MEETINGS.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.—Meeting of the Toronto Section will be held at the Engineers' Club, 96 King St. West, at 8 p.m., Friday, March 28th. Secretary, H. I. Case, 709 Continental Life Bldg., Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, T. S. Young, 220 King Street W., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Décary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson, Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

An Engineering Weekly

RAILWAY SWITCHES AND TRACK LAYOUTS

BY J. L. BUSFIELD, B.Sc.*

In the past few years a great deal of attention has been paid to the design of railway switches and turnouts. It is not so very many years ago since railway engineers put in "any old thing" for a switch, whereas in these days of scientific refinement it is a subject which is dealt with on a proper mathematical basis. It is not the writer's intention here to deal with a number of abstruse mathematical calculations, but to give a general description of the construction of switches and their assembling in groups to give yard layouts, and the problems that railway men have to contend with in designing these layouts.

A brief description of the construction of a standard switch with the names of the various component parts is first necessary. Referring to Fig. 1, the switch is made up of two switch points "aa," a frog "b," two guard rails "cc," and the connecting or closure rails "d," the through rails "ee" are called the stock rails; "ff" are the points of the switch, "gg" the heel of the switch, "h" is the toe of the frog, and "i" is the heel. The distance from the point of switch "f" to the point of frog is called the "lead."

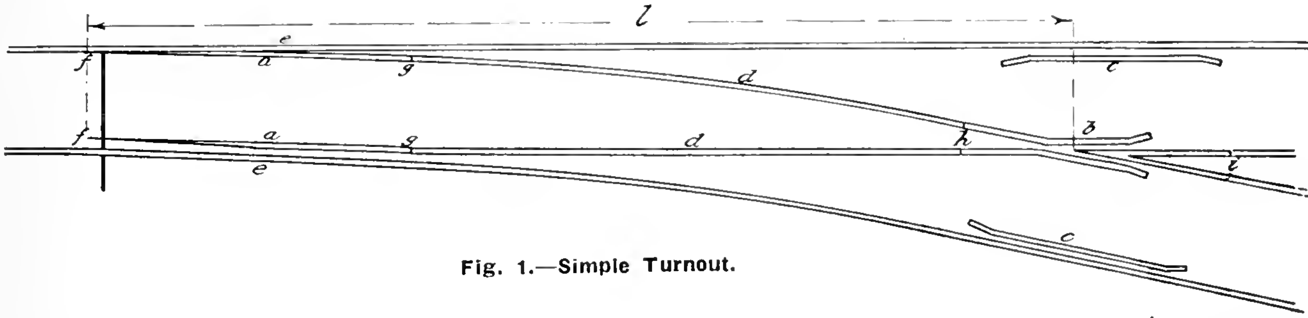

Fig. 1.—Simple Turnout.

Attached to the inside of the outer rails opposite the frog are two guard rails, varying from 8 to 12 feet long, placed there to control any side-play of the wheels passing over the frog, and so preventing the flanges mounting the rail instead of passing the point of the frog in the flangeways provided.

These guard rails are usually made from standard rail and are fastened to the running rail and the ties by special castings. The ends of the rails are splayed outwards to facilitate the passing of the wheel flanges into the flanges.

The two features which vary in different switches are the angle of the frog, and the lead. The frogs are always designated by a number, which denotes the inclination of the turnout rail to the main track, e.g., a No. 7 frog means that the two legs are inclined at an angle of 1 in 7. Now, the frogs in general use for ordinary railway work are as follows:

Frog No.	Angle.
6	8°–48 ft.
7	8°–11 ft.
8	7°–9 ft.
9	6°–22 ft.
10	5°–44 ft.

The No. 6 frog is only now being used in very exceptional cases, as it has been found to require too sharp a curvature to be able to accommodate the large equipment in general use; the No. 7 frog is also being largely discarded except on branch lines and freight tracks. The No. 8, 9 and 10 frogs are in general use, and in some cases frogs as flat as the No. 12 are used, such as for main line connections from a through main line to a local.

The switch points are usually made about 15 feet long, but a number of roads are adopting the 16-ft. 6-in. points in order to give an easier riding switch. They have a "throw" of 6 inches at the point, and at the fixed end there is a distance of 5½ inches from guage line to guage line of the two rails.

Now, after the frog and the points are selected they have to be connected with a curve on one rail and a piece of straight track on the other, or even a curve on both rails, as the case may be, but taking the case of one straight track and the curved turnout, the switch points and frog have to be spaced at such a distance apart that a curve of uniform radius will be tangential to the heel of the switch and the toe of the frog. The distance apart of the point of switch and the point of the frog (the lead) and the equivalent radius and degree of curve is given in the following table, for use with 15-ft. switch points:

* Assistant Engineer, Montreal Tunnel and Terminal Construction.

No. of frog.	Actual lead.	Equiv. radius.	Equiv. degree of curve.
7	60 ft.	410 ft.	14°– 0 ft.
8	66 ft.	573 ft.	10°– 0 ft.
9	75 ft.	702 ft.	8°–10 ft.
10	82 ft.	1,011 ft.	5°–40 ft.

This equivalent radius of 410 feet just about corresponds with the minimum radius that most standard railways are

Fig. 2.—Ladder at Angle of Frogs.

willing to adopt, even for spur tracks and sidings away from the main line, the large switching and main line engines being unable to cope with sharper curves without frequent derailments.

Whatever design for a layout of switches and tracks is considered, the three details given in the table above have to be borne in mind, i.e., the angle of the frog, the lead and the curvature.

The three commonest positions of the switch are in the simple turnout, the crossover and the "ladder." In the design of a crossover the piece of track between the two main

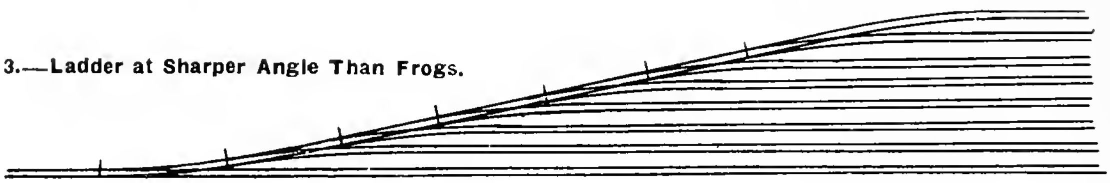

Fig. 3.—Ladder at Sharper Angle Than Frogs.

tracks and connecting the two frogs is always made straight and the distance in between the frogs is easily obtained, knowing the frog angle and the distance between track centres.

In the case of No. 10 frogs and 13-ft. centres between tracks this distance is 34 ft., thus making the total length of crossover 198 ft.

The design of a ladder requires more consideration, and conditions such as property limits, track capacity, etc., have to be dealt with, but if there are no such

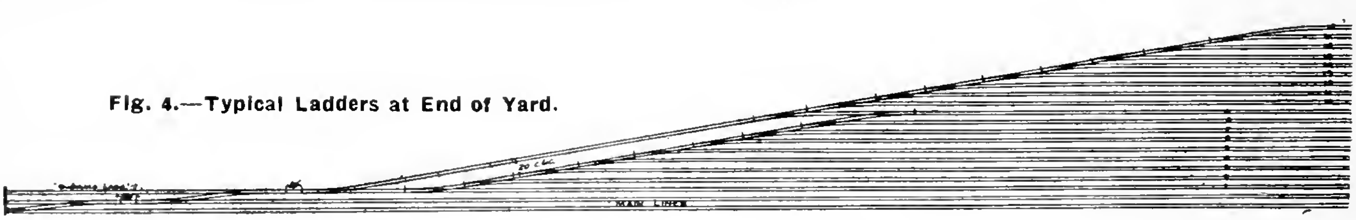

Fig. 4.—Typical Ladders at End of Yard.

limiting conditions a simple straight ladder can be laid out so that the ladder track is at the same angle with the yard tracks as the angle of the frog that is to be used in the switches, in which case the frogs are set at the intersection of the gauge lines of the two rails, as is shown in Fig. 2. If the first frog in the ladder is located it is a simple matter to find the distances between all the frogs on the ladder, e.g., if No. 8 frogs are to be used, and the tracks are 13-ft. centres, the frogs will be 8 × 13 = 104 feet apart, so that if there are going to be, say, 7 tracks connected to the ladder the last track will be about 700 feet shorter than the first. This is usually rather a serious situation as it is almost always desirable to get the longest track possible, or at any rate to get the tracks as nearly the same length as possible, but it is readily seen that in order to make the last track longer it is only necessary to increase the angle which the ladder makes with the main yard tracks, the effect of this being to reduce the distance between the frogs, which do not now point in the same direction as the yard tracks, and so have to be placed closer to the first track in order to allow room for the necessary curve between the heel of the frog and the tangent, as is shown in Fig. 3. Now, the maximum angle at which the ladder track can be placed is fixed in this way: the distance from the point of switch to the point of frog (assuming the use of No. 8 frogs) is 66 ft., the standard distance from point of frog to the heel is 9 ft., and the closest distance that the point of one switch can be placed to the heel of the frog of the preceding switch is 3 ft., to allow for the angle plates of the joint, thus we have the minimum distance between frogs is 78 ft., thus giving an angle of 1 in 5.2 for 13-ft. centres or 1 in 6.5 for 12-ft. centres. Using these figures in a yard of 7 tracks there would be an increased length in the last track of about 180 ft. and a proportional increase in the other tracks.

It is not usual in good railway practice to put more than 9 or 10 tracks on the one ladder, as this has been found by experience to be the maximum number that can be efficiently operated by one engine, except in special cases; for instance, where the tracks are used solely for storage purposes. Fig. 4 shows a typical arrangement of tracks with two ladders serving 18 tracks in all.

It is usual to extend the first track in the opposite direction to the yard, to make a switching lead, as shown in Fig. 4; this lead allowing switching engines to make up the various trains without encroaching on the main lines.

In some instances it is desirable to put in even steeper ladders than can be done by the methods described above, especially in cities and towns where land is valuable and must be occupied to the greatest possible advantage. In cases like this a ladder can be used, as shown in Fig. 5.

This ladder, although giving the advantage of longer tracks, has the disadvantage of having the switches on op-

posite sides of the main track, so that the switchmen have to be continually crossing and recrossing the track in front of the switching engine and trains.

The main ladder track has to be placed at such an angle to the yard tracks that there will be enough curvature between the heels of the frogs in the ladder track, and the straight tracks to which they connect, to allow a second switch to be placed within this curve. The primary switches in the ladder track are directly connected to each alternate track, and the secondary switches pick up the remaining tracks. The typical layout in Fig. 5 shows the method better than it can be described. A certain amount of variation is possible in the angle of the ladder track, but it is limited by the lengths of the switches, the frog angles and the track centres.

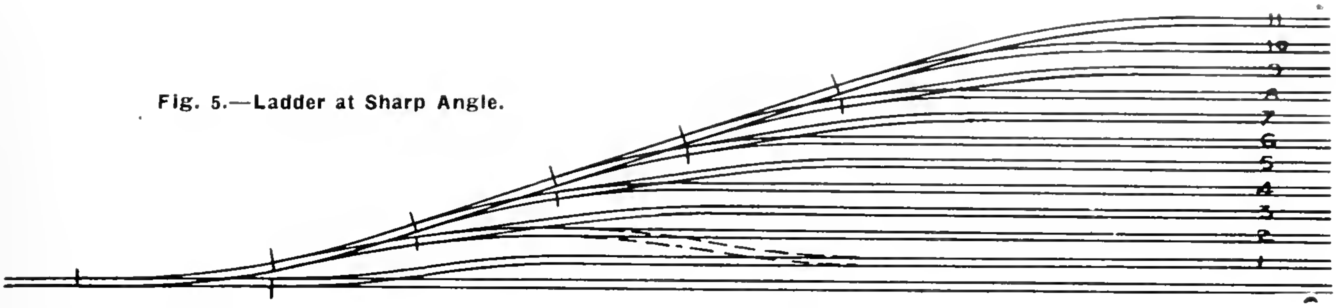
As will be seen from the plan of this type of layout, it is not possible to connect the first, or No. 1 track to the ladder, but this difficulty is easily overcome by running it into the main line, or else, as shown dotted, from No. 2 track.

It frequently happens that the ladder track at the end of a yard cannot be located where the main tracks are on a tangent; in which case the ladder track has to be built to the same curvature as the main line, but if the yard is on the outside of the curve, it becomes difficult to lay down the switches without excessive curvature and the limit is reached when the curvature of the switch added to the curvature of the main line reaches the maximum permissable curvature.

Modern freight classification and storage yards are very often designed so that all the tracks forming one "set" are the same length, thus reducing the difficulties of operating the yard through having a number of tracks of greatly varying lengths. A typical layout for a yard of this nature is shown in Fig. 6, giving two main yards for the sorting of inbound and outbound freight, with a space between them for storage, caboose, and engine tracks, yard offices, etc.

A type of combined switch and crossover, known as a slip switch crossing, is shown in Fig. 7, and is being largely used in places where great flexibility of movement is required. As will be seen, this crossing will give two alternate routes for a train coming in any of the four directions. In construction it is a regular diamond crossing, with the sides connected with switch points and closure. It cannot be conveniently used for tracks which cross at a sharper angle than 1 in 7 because the switch points, frogs, guard rails, etc., become too crowded together to permit of their proper construction.

Fig. 5.—Ladder at Sharp Angle.



In a slip switch of this nature the movement of all the points is made by one lever being placed at the centre of the crossing, but the use of this crossing is not considered very advisable except in yards with interlocking apparatus, owing to the increased liability to accident through two trains coming together, either "head on" or "sideswiping."

These slip switch crossings have enabled a design to be made for track layouts which is now being used in various forms in general large passenger terminals. The general idea of this layout is shown in Fig. 8, and it will be readily seen that great flexibility of train movement can be obtained, as either an incoming or outgoing train can keep to its correct track practically to the end of the platform to or from which it is bound. For instance, an outgoing train from platform 7 will take the switch to the right at the point "b" and thus be on its own right-hand track, and be independent of trains arriving at the platforms beyond No. 7. Similarly an incoming train will keep to the right-hand track as far as possible and only cross over to its own platform track as close to it as possible. The switches marked "b" in Fig. 8 are slip switch crossovers similar to that shown in detail in Fig. 7, but those marked "a" have the connecting switch on the lower side only, so are "half slips."

This type of double ladder with slip switches is rapidly coming into use in terminals where a large number of trains are handled, as it does away with a great deal of the congestion that is liable to take place through one train having to wait outside the terminal while another one is just leaving. This leads to delays, one delay leads to another, and the working arrangements of the whole terminal are upset.

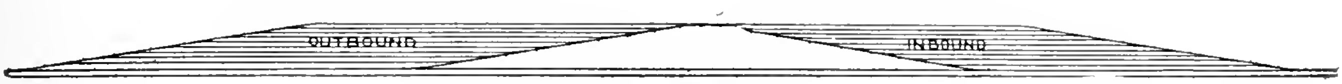


Fig. 6.—Parallel Ladders.

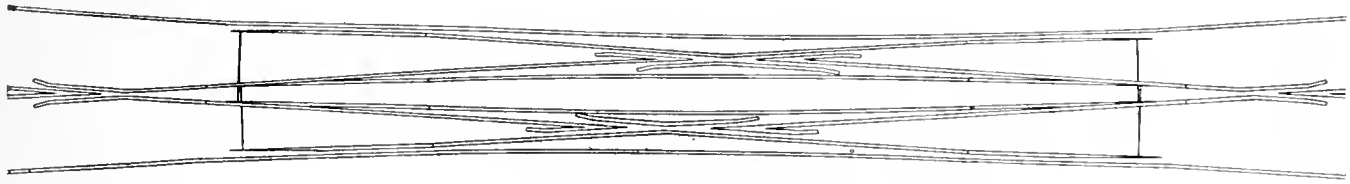

Fig. 7.—Slip-Switch Crossing.

whereas the double ladder permits the greatest number of movements either from one platform to another or of the main line trains, to be made without interference. A layout of this nature can only be economically used where an interlocking plant is in operation.

In main line work refinements have to be made in the switches to make them easy riding, such as the use of longer switch points, and spring frogs. The latter are made with one arm pivoted in such a way that ordinarily the main line rail is continuous, but when the turnout is being used the wheel flanges of the cars push this arm to one side, against the pressure of a strong spring.

On the railways in Great Britain even greater refinements are carried out with switches, to meet such conditions as are often obtained at junctions between stations where trains will frequently pass from the main line to the branch at as high a speed as 60 miles an hour. To meet these requirements the switch points are made very much longer and the whole switch is constructed on the principle of a spiral curve.

Great strides have been made in this subject during the past years, but even now it is quite possible to see yards with a jumble of switches at their extremities which might have been made into orderly ladders, and with "stub" switches which should be on the scrap heap; but these will all no doubt be replaced in the course of a few years with the neat and efficient layouts that are now in general use in modern track construction.

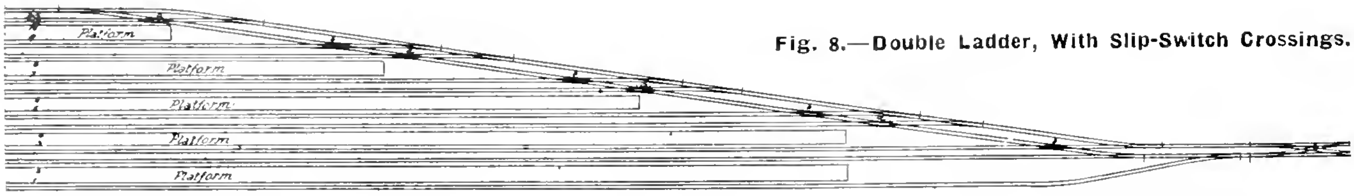

Fig. 8.—Double Ladder, With Slip-Switch Crossings.

SEWER CONSTRUCTION.

The laying of sewer pipe by contractors in treacherous ground of the quick sand type usually means pecuniary loss for the contractor if he was unaware, at the time of making his bids, of the soil of the above type he would encounter. A description of the troubles and difficulties of this kind unexpectedly run into is given in a paper presented before the Iowa Engineering Society, by C. P. Chase, and reads as follows:—

A contract was let in October, 1910, to Mr. C. R. Nichols, embracing 5½ miles of 8-in. to 15-in. pipe sewers, with manholes and flush-tanks, and a reinforced concrete septic tank with dosing chambers and sand filters.

It was expected to begin work at once, but the contractor was busy and let it go over winter. Conditions early in 1911 were ideal; but the contractor failed to begin, though constantly urged. At last, in July, 1911, work was begun on the disposal plant by a sub-contractor and the grading done and excavation made for the tank. Here the contractor, tied up by other affairs, abandoned the work.

The council gave notice to the bonding company to take up the work, and very shortly it came forward and agreed to complete the job. The contract was placed in the hands of the Lytle Construction Company, of Sioux City, which immediately began operations. The first trenching machines steamed up on Aug. 20, 1911, and conditions seemed to be favorable for completion that season.

In the deepest cut of some 21 ft. the machine cut to grade with no bracing and ditch dry as a bone. A large number of laterals on the east side were built, with cuts from 7 to 20 ft., with an occasional brace, the machines making in some instances as high as 650 ft. in one day on a 6 to 8-ft. trench. The laterals were nearly in before cold weather, but in the meantime, on the other branch of the main sewer, something had happened. As will be remembered, 1910 and 1911 to the fall of the latter year were very dry: this was especially true around West Liberty. A rain of several days came about Oct. 1, and the dry ground in 48 hours was filled with water, there to remain.

Quicksand.—In a recent English lawsuit a lawyer described a certain quicksand that had resulted disastrously to his client as "an oily, slithery, nasty mess, where men would speedily sink to their death if not rescued." There you have West Liberty. Molasses, soft glue, or crude tar come nearest. By various sewer men it was designated as quicksand, floating clay, sea mud, boiling sand, and worse. I would designate it as a silt deposit of some ancient lake bed. It varied from a fine, silty sand to a molasses-like mud, in which men frequently sank to their hips and were pulled out with ropes, and it would go anywhere that water would.

The first encounter with this was fought out in the usual way, with hand-driven sheeting afterward removed. One block about 300 ft. long, put in in this way, was clear and in good shape when finished; later the sides settled and the whole line was heaved out of line and grade and nearly every pipe crushed. The various ordinary expedients of sewer building were tried without much success.

First a small section was taken out by hand, driving the sheeting down as the excavation proceeded; when to grade short ship lap was driven about 2 ft. below grade and left 2 ft. above. Straw, cinders, stone, brickbats and other material simply floated away, the great trouble being that after the pipe was laid the bottom of the trench would raise up from pressure of the sides and break open the joints or even crush the pipe.

It was seen that although expensive, more strenuous methods must be adopted, and that perfectly tight sheeting must be used, of sufficient strength to hold the side pressure and that it must be secured and left in. It was also found to be impossible to depend on hand driving. An Arnott hammer and a proper outfit were secured. To prepare for sheeting, the ditch was opened with a trenching machine as deep as the banks would stand, which was from 6 to 9 ft., much better success attending machine digging than hand digging. Then 2 x 12-in. tight sheeting was driven about 3 ft. below the grade of the flow line of the pipe, thoroughly cross-braced and spiked. It was allowed to remain in the trench. Any attempt to remove the sheeting was attended with almost immediate disaster.

Two methods of placing and driving the sheeting were employed. In both cases the excavation was carried down 6 to 9 ft. with a trenching machine, temporary braces being set to hold the clay banks until the stringers could be placed.

In the first method a set of 4 x 6-in stringers was placed at the bottom of the machine-dug trench, 2 x 6-in. stringer being placed next to the bank and separated from the 4 x 6-in. stringer by a 2-in. block, much care being taken to have them set plumb, otherwise the sheeting would drive crooked. A similar set was placed about 3 ft. below the surface of the ground and the sheeting driven between the 2 x 6-in. and the 4 x 6-in. sets. A timber frame 16 ft. high was constructed on a platform wide enough to span the trencn, and the hammer suspended on a trolley running on a 7-in. I-beam set transversely to the trench at the top of the frame. The platform was build on skids parallel with the trench, so that it could be easily moved forward as the driving progressed. The hammer was operated between two pairs of guide rods made of galvanized iron pipe, a gasoline engine and hoist being used. With this method and equipment an average of about 60 pieces of 2 x 12-in. timber, 18 ft. long, could be driven per day at a cost for labor of 50 cents per lineal foot of trench and a total cost for sheeting of about $3.20 per lineal foot. It was hard to keep the outfit upright and steady, and this reduced considerably the driving power. Only one plank could be set on each side of the trench at a time, making it necessary to move every foot, which was impracticable and too expensive.

In the second method blocks were set between the 4 x 6-in. stringers and the 2 x 6-in. stringers omitted. The steam hammer was handled by a derrick with a 20-ft. boom, the guide rods in this case being made fast to the hammer, and sliding through iron loops fastened to the end of the boom. The derrick was erected on a platform similar to the one described above, and in such a way that the foot of the derrick was over the centre of the trench. In this way about 34 pieces of sheeting could be driven from one position. The derrick was then moved forward and the driving continued. Laborers set up the sheeting ready for the driver as soon as the stringers were in place, so that the hammer could be kept constantly at work. With this method the number of pieces driven per day was increased about 30 per cent., with a corresponding decrease in cost.

Removing Material.—The quicksand was taken out in buckets of ¼-cu. yd. capacity. To handle the buckets, two derricks made of 6 x 6-in. timbers, with 20-ft. booms, were erected on opposite ends of a platform made to span the trench. A four-post frame made of 6 x 6-in. timbers properly braced held the derricks in place. On the platform within the frame a 4-h.p. gasoline engine furnished power for the hoists, which were so arranged that one man could operate both derricks. This apparatus was employed to handle the steam hammer, and when hitched to a scraper was also used for backfilling. The blocks were so arranged that in raising a full bucket from the trench its weight pulled the boom around to the side of the trench where the bucket was to be emptied. Seven men were ordinarily sufficient to operate this device, doing more and better work than 14 formerly accomplished by hand. Without it or something similar it would have been almost impossible in the worst places to make any progress against the quicksand; for in spite of tight sheeting, carefully driven, the sand ran in through the smallest cracks and boiled up from the bottom. Occasionally after half a day's work there were no results apparent in the trench.

Preparing Bottom.—With the sheeting in place, and the trench excavated, special methods had to be devised to prepare for pipe laying. Cinders, straw, brickbats, piling and concrete were experimented with, and at last concrete was chosen—first, to keep the sheeting from pressing in and crushing or disturbing the pipe, and, second, to obtain a pipe bed. The concrete placed one day was not used to lay pipe on until the next. Half of the diameter of the pipe was buried in concrete to distribute the weight and prevent crushing.

In some places where concrete was being placed for foundation the sand boiled up through the concrete before it had time to set and rendered it useless. To overcome this, inch boards were laid lengthwise in the bottom of the trench the full width and nailed together. They were then worked down through the sand and water as far as they would go, sufficient excavating having been done to permit the boards to be worked down to a point 6 or 8 in. below grade. The sand and water were then cleaned off the boards and the concrete placed. The time saved in this way more than paid for the boards, and a much better foundation was obtained.

Of all the equipment which the contractor had on the work the steam hammer and the derrick device for handling wet excavation gave him the best returns on the investment for plant.

Occasionally there would be an oasis in this sea of antediluvian mud where a good bottom could be secured by mixing cinders with it. This seemed to work where it was sticky, with clay predominating. It would fill up and bind, but if fine sand predominated, cinders were useless.

All pipe was eventually covered with dry earth and the fill was compacted by tamping to a depth of several feet.

Railroad.—Where the 15-in. main crossed the Chicago, Rock Island and Pacific right-of-way an attempt was made to tunnel the main tracks; but the sand was so bad that it was finally found necessary to drive a temporary bridge of 15-ft. span under each of the two main tracks and make the excavation in open cut. Under the stringers of the bridges for a space of several feet horizontal sheeting was set, and below this 2 x 8-in. sheeting was driven down below grade by hand. Outside the main tracks steel sheeting was driven and later pulled, using a 6-ton Triplex block. Cast-iron pipe was used across the right-of-way, and it was not thought necessary to leave sheeting in the trench. As the sand offered no foundation for the cast-iron pipe, brickbats and concrete were placed under the joints. The excavation was carried down below grade, a wagon load of brickbats dumped at the place where the joint would come, and about one-half or three-fourths of a cubic yard of concrete dumped from large buckets on the brick. So much sand was taken out at this place that the banks settled considerably, more than 1 ft. at one point. This line of sewer, however, showed up well on final inspection.

The contract, which ordinarily would take six months, was completed in November, 1912, and much credit is due to the contractor for the gameness with which he stuck and finished the work.

ROAD GRANTS IN ENGLAND.

Considerable dissatisfaction exists among highway authorities in London, England, at the manner in which the Road Board is dispensing financial assistance for the repair of roads damaged, chiefly by heavy motor traffic. The board hinted at the outset that it was prepared to make grants and loans to the authorities in the metropolitan police area up to the amount of £250,000. But it seems that no authority can get a grant unless it is itself prepared to spend three or four times as much as the grant, and is considered that this policy is a direct incitement to local bodies to spend more money than the circumstances of the case demand. Road board grants, it is claimed, should be unconditional, and that local authorities should not be forced to spend large sums out of the rates for the special benefit of motor traffic. So strong is the resentment of the authorities on this policy that the subject is to be raised in parliament at the first favorable opportunity.

STREET PAVING IN ENGLAND.

The Metropolitan Paving Committee, of London, England, have recently issued their tenth annual report relative to paving work compiled from information furnished by the engineers to the authorities concerned. As this information is very complete in its way, it may be of interest to Canadian engineers as regards cost comparisons. It should always be remembered that our more rigorous climate and the difference of the labor wage, lessens the value of this report as far as Canadian practice is concerned. We are of the opinion that a perusal and study of its contents is nevertheless both advisable to all interested in road building.

The brief summary of the work done is taken from The Surveyor, of London, England, February 21st, 1913. The prices mentioned have been changed to the decimal system of coinage to suit our Canadian readers.

Principal Kind of Paving Laid.—The bulk of the paving laid down in the districts mentioned in the returns during the year appears to have been creosoted soft wood, although in some instances other kinds of paving predominated. Large areas of tar-macadam were laid in some districts, principally in limited traffic residential and business streets, while a large amount of tar-spraying has also been undertaken.

Foundation.—In some boroughs a foundation of Portland cement concrete 9 in. thick (in one case 12 in.) has been adopted, while in others a 6-in. foundation has been deemed sufficient. There is a decided tendency to increase the thickness of concrete foundation, owing to the detrimental effect of heavy motor traffic.

Effect of Motor Traffic.—Motor traffic is considered to be detrimental to macadam-paved roads, and the majority of the borough surveyors are of opinion that motor traffic has increased the cost of the upkeep of the roads.

Saving on Tar-sprayed Roads.—Considerable saving continues to take place in those boroughs where the tar-spraying of macadam roads is largely undertaken. From the appended information it will be seen that a very considerable saving has been effected in the boroughs of Fulham, Greenwich, Hammersmith and Wandsworth in the cost of scavenging, watering and maintenance of highways since the adoption of the system of tar-spraying macadamized roads. It is, moreover, generally agreed that a great improvement in the road results from tar-spraying.

The returns sent in during the past year have been put in tabulated form, and may be briefly summarized as follows:—

Greenwich.—Some 3,600 super. yds. of tarred macadam, 4 in. deep, were laid in this borough. The macadam was consolidated with the steam roller and laid on an old foundation, the subsoil being gravel. The cost of laying per yard super. was 79c. without foundation, the work being carried out by the local authority. The surveyor mentions that 47,227 super yds. have been tar-sprayed in the borough at a total cost of $2,258.

Hammersmith.—In Stamford Brook Road tar-macadam, composed of Trinidad Lake bitumen and granite mixed, 3 in. thick, with a sealing coat of refined Trinidad Lake bitumen, was laid on a foundation of old macadam at a cost of 90c. per yard super. In another thoroughfare, with limited traffic, tarred-slag macadam, 3 in. thick, was laid on an old foundation at a cost of 67c. per yard super. In this borough 275,164 super. yds. have been tar-sprayed at a cost of $2,931.11.

Hampstead.—Hard and soft wood, lithofalt block paving, lithomac paving and tar-macadam were laid in this borough during the past year. The 8-in. by 3-in. by 4-in. creosoted deal blocks were laid with close joints run in with a mixture of boiling pitch and creosote oil, grouted with Portland cement and top dressed with fine shingle on an old 6-in. foundation broken up and a new Portland cement foundation 9 in. thick, including 1 in. floating formed. The foundation was laid by the local authority, the paving by a contractor at a cost of from $1.36 to $1.38 per yard super. without foundation. The 4-in. Jarrah blocks which this paving replaced had been down for eleven years in these heavy traffic roads. In Heath Street, where the traffic is limited, these blocks were laid in the same manner on an existing foundation made good and refloated with Portland cement and sand, at a cost of $1.70 per yard super., including the work of remaking the foundation. The 5-in. deal blocks which this paving replaced had been down nineteen years.

In Finchley Road, a heavy traffic thoroughfare, 8-in. by 3-in. by 3¼-in. sectional Jarrah blocks were laid, the courses divided by fillets of ¾-in. in depth and 1/12 in. in thickness, the joints being filled in with a mixture of boiling bitumen. They were laid on an existing foundation made up to the proper level with Portland cement concrete, and refloated with Portland cement and sand at a cost of $3.29, including the cost of the work of remaking the foundation. The Jarrah blocks which this paving replaced had been down eleven and twelve years. The surveyor states that this sectional block paving has proved very satisfactory after an experience of seven years; the wear is smooth and even, and there is no corrugation of the paving as in ordinary hardwood paving.

Lithofalt blocks, 9 in. by 4½ in. by 1¾ in., were laid in Belsize Road, where the traffic is considerable. They were laid on wet floating, on an existing foundation, made up to suit the new paving. The blocks were supplied by a contractor, and the work was executed by the local authority, the cost per yard super. being $1.72 with foundation.

Lithomac paving, 2 in. in thickness, was laid in College Crescent, where the traffic is considerable, at a cost of $1.23 per yard super. with foundation.

Holborn.—Most of the paving laid in this borough consisted of compressed rock asphalt 2 in. thick, the Portland cement concrete foundation being, in nearly every case, 9 in. thick. The rock asphalt was compressed with heated pelons, the cost per yard super. varying from $2.47 to $3.35 with foundation, and $2.19 to $2.25 without foundation. This paving has worn well. Some Trinidad Lake asphalt macadam, 3 in. thick, was laid at a cost of $1.15 per yard super. without foundation.

In Chancery Lane, where the traffic is considerable, creosoted Swedish deal blocks, 3 in. by 9 in. by 5 in. have been laid in pitch grout finished in cement, joints 1/10 in. in thickness, on a Portland cement concrete foundation, 9 in. to 11 in. in thickness, at a cost of $3.22 per yard super. with foundation, and $1.85 without foundation, the annual cost of maintenance per yard super. being 24c.

Kensington.—The return from this borough contains particulars of a new description of paving—namely, camphor wood blocks, 9 in. by 3 in. by 4 in., grouted tar pitch and cement, and laid on a 6 in. Portland cement concrete foundation at a cost of $2.73 without foundation.

Creosoted deal blocks, 8 in. by 3 in. by 4 in. or 4½ in. or 5 in., were laid, grouted tar pitch and cement on a 6-in. Portland cement concrete foundation, at a cost of from $2.23 to $2.50 with foundation, and $1.63 to $1.80 without foundtaion. In Notting Hill Gate the wood paving which this paving replaced had been down twelve years, and in residential thoroughfares the paving replaced wood paving which had been laid from sixteen to twenty years previously.

Kensington asphalt clinker blocks were laid in residential thoroughfares by the local authority.

ELECTROLYSIS FROM STRAY ELECTRIC CURRENTS.

By A. F. Ganz, M.E.*

At a recent meeting of the New England Association of Gas Engineers, Prof. Ganz delivered the following interesting lecture on Electrolysis from Stray Electric Currents. Written in clear style and apparently free from the assumption that those reading are all highly versed in electric technology, it should be instructive and pleasant reading for all.

A Definition and Theory of Electrolysis.—Electric current may be conducted in two ways: First, by metallic conduction; and, second, by electrolytic conduction. Metallic conduction occurs when an electric current passes through a metal, and is characterized by the fact that no chemical change is produced in the conductor, the only effect being the production of heat. When electric currents, therefore, pass through metallic conductors, such as copper wires, rails, or pipes, they produce no change in these conductors except to raise their temperature. Under all ordinary conditions stray electric currents found on underground pipes

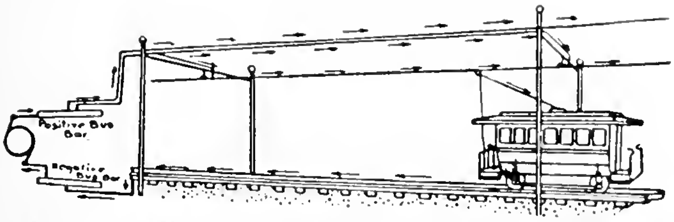

Fig. 1.—Diagram Showing Path of Current from Generator through Positive Feeders, Trolley Wire, Car and Rails.

are not sufficiently large to appreciably heat these pipes. Under abnormal conditions pipes may, however, carry stray currents of sufficient magnitude to produce heating at moderately high resistance joints.

Electrolytic conduction occurs when an electric current passes through an electrolyte, and is characterized by the fact that the electric current is transmitted by a corresponding transfer of ions in solution, with the production of chemical decomposition at the electrodes where the current enters and leaves the electrolyte. Electrolysis may, therefore, be defined as chemical decomposition produced by an electric current. Electrolysis is usefully applied in the arts for the refining of metals and for producing chemical compounds. The writer wants to discuss here the destruction of underground structures caused by electrolysis from stray electric currents which reach these structures.

Chemical compounds in solutions of water, constitute the ordinary electrolytic conductors. Pure water itself has such a high resistance that it may practically be considered a non-conductor. It is for this reason that an iron pipe full of ordinary city supply water does not have a lower resistance than the same pipe without water. Water is, however, readily made conducting by the addition of small amounts of salts, and conduction through water is, therefore, always electrolytic.

The following is a brief explanation of the theory of electrolytic conduction. When a salt is dissolved in water, some of the molecules separate or dissociate into two parts, one part having a positive electrical charge, and the other a negative electrical charge, and these parts are called ions. The metal parts (or the hydrogen) constitute the positive ions, and the acid parts the negative ions. For instance, copper sulphate, $CuSO_4$, when dissolved in water, dissociates into the positive metal ion Cu and the negative acid ion SO_4. An electric current is transmitted through an electrolyte by the transfer of these ions. The electrode by which the current enters the electrolyte is called the anode, and the one by which the current leaves is called the cathode. The metal or hydrogen (positive) ions travel in the direction of the current and carry positive electrical charges to the cathode, and these metal ions, called cations, are deposited upon or are liberated at the cathode. The acid (negative) ions travel against the current and carry negative electrical charges to the anode, and these acid ions, called anions, will corrode the anode if it is a metal which combines chemically with these anions. The cathode is not corroded. With an electrolyte of copper sulphate dissolved in water, a copper anode corrodes into copper sulphate and dissolves, while metallic copper is deposited upon the cathode. If the electrolyte is common salt dissolved in water, the anions are chlorine, and an iron anode would be corroded, the iron forming ferrous chloride; the cations are sodium, and these would decompose the water present and liberate hydrogen at the cathode. These examples furnish an illustration of the fact that the corrosive action of the current results in supplying the electrolyte with an equivalent of the amount of salt decomposed by the current, so that the electrolyte is continually replenished with salt and its electrolytic conducting power is thereby maintained. This salt will contain metal ions of the anode or hydrogen, and may be different from the original salt which started the action.

Street soils, when entirely dry, do not conduct electric currents. Under ordinary conditions, however, street soils contain considerable water with salts in solution, generally chlorines, and this makes them electrolytic conductors. When an electric current passes through soil it, therefore, does so by electrolytic conduction and by corresponding chemical decomposition at the electrodes. Where an electric current leaves an iron pipe for soil it corrodes the iron by this action of electrolysis. It has been claimed in the past that soils may conduct metallically; but this has been disproved, and it is now recognized that conduction of electric current through soil is always electrolytic.

The rate at which ions are liberated at the electrodes is proportional to the current strength. With an oxidizing anode, such as iron or lead, the mass of anode corroded by one ampere in 1 second is equal to the electro-chemical equivalent of the metal of the anode. This is 0.00029 gram for iron (ferrous). From this the mass of iron corroded by 1 ampere in 1 year is $0.00029 \times 60 \times 60 \times 24 \times 365 \times 0.002205 = 20$ pounds (approximately). The electrochemical equivalent for lead is 0.0010716 gram, and the mass of lead corroded by 1 ampere in 1 year is $0.0010716 \times 60 \times 60 \times 24 \times 365 \times 0.002205 = 74$ pounds (approximately).

The separation of the metal or hydrogen ion from the electrolyte in the cathode absorbs energy from the electric circuit and generally produces an electromotive force in the opposite direction to the current. The oxidation of the anode supplies energy to the circuit, generally producing an electromotive force in the direction of the current. If the oxidizing anode is of the same metal that is being deposited upon the cathode, and if the electrolyte is the same at the anode and cathode, then there is no resultant electromotive force due to the electrochemical actions, and the only electromotive force consumed is that due to the resistance of the electrolyte in accordance with Ohm's law, exactly as with a metallic conductor. If the metal deposited at the cathode is different from that oxidized at the anode, or if hydrogen is liberated at the cathode, or if the electrolyte at the cathode is not of the same composition or density as at the anode, then there will be a resultant electromotive force, which may be either

*Prof. of Electrical Engineering at Stevens Institute Technology.

in the same or in the opposite direction as the current. It has been assumed by some writers in the past that no corrosion from electrolysis can take place if the voltage between two metallic conductors in soil, such as between pipe and rails, is less than 1.5 volts, because this is the dissociation voltage of water. This, however, is entirely wrong, and it has been proven by many investigations, also by practical experience, that the amount of corrosion produced by electrolysis is independent of the voltage, except in so far as this determines the amount of current flowing, and that the smallest fraction of a volt can produce corrosion from electrolysis under suitable conditions, and this is now generally recognized by electrical engineers.

A large number of laboratory tests have been made to determine whether electrolysis is produced when an alternating current flows from a metal to an electrolyte; for example, from a pipe to surrounding soil. These experiments indicate that a slight amount of electrolysis may be produced by an alternating current, which is generally less than 1 per cent. of the amount of electrolysis produced by a corresponding direct current. It must be remembered, however, that, in the case of alternating current, electrolysis would be produced wherever there is a flow of alternating current between a metal and soil, while with direct current metallic anodes exist only at ½ the points where current flows between metal and electrolyte; namely, where current leaves the metal.

Sources of Stray Electric Currents.—Stray currents are electric currents which have leaked from grounded electrical distribution systems and flow through ground and through underground structures. Grounded telephone and telegraph lines produce electric currents through ground of such very small magnitudes that their effects upon underground piping systems can be neglected. Direct current, electric lighting systems, in which the distribution is on the Edison 3-wire plan, with the neutral conductor grounded, are in American practice provided with such large neutral conductors of copper that practically no stray currents are produced from such systems. This grounding of the neutral in Edison 3-wire systems is to serve as a safety measure, and is not for the purpose of using the ground to carry current.

The secondaries of transformers are also frequently grounded to underground pipes for the purpose of preventing a high and dangerous voltage from existing between the secondary circuit and ground. Such ground connections, however, do not produce flow of current from pipes to ground and, therefore, such grounding of transformer secondaries does not cause danger from electrolysis.

Electric railways, using the running tracks for return conductors, often produce comparatively large stray electric currents through ground, and these are the only sources of stray currents which need be considered in practice. Direct current is very generally used for such electric railways, and it is the common practice to supply current to the care from an overhead trolley wire or from a third rail, and to return this current to the power station through the running tracks, supplemented where necessary by return feeders. A single-trolley electric railway is shown diagrammatically in Fig 1, in which the path of the electric current, from the positive terminal of the generator through the circuit and back to the negative terminal, is shown. The running tracks consist of rail lengths about 30 feet long, and these are mechanically fastened together by fishplates which consist of steel plates bridging across the rail ends and bolted to both rails. Such fishplates, while mechanically fastening the rail lengths together, do not form good electrically conducting connections between the successive rail lengths. For this reason, copper wires or straps, called rail bonds, are generally used to bridge across the abutting ends of the rail lengths for the purpose of affording a good electrically conducting path between successive rail lengths. The two rails of a single-track road, or the four rails of a double-track road, are also generally connected together at frequent intervals by cross bonds so that the 2 or the 4 rails may be available for the return of current. Instead of using copper rail bonds, the rail ends are sometimes welded together, or soft steel plates are welded across each side of the abutting rail ends, thus forming both a strong mechanical and a good electrically conducting connection between the successive rail lengths. A well bonded railway track should have a conductivity not less than 80 per cent. of the equivalent conductivity of continuous rails. To give some idea of the relative conductivity of steel rails, it may be stated that a single rail, weighing 90 pounds per yard, which is a size commonly used where the traffic is heavy, has about the same conductivity as a copper wire 1 inch in diameter. Thus the 2 rails of a single-track line, or the 4 rails of a double-track line, laid with 90-pound rails and well bonded, afford a good conducting path for electric current.

In the simplest form of single-trolley railway, already shown in Fig. 1, the rails are connected to the negative terminal of the generator at the power station, and the only path for current to return to the power station is by way of the running tracks. If the running tracks are laid upon wooden ties above ground, with broken stone for road ballast, as is common on steam railroads which run on their own right-of-way, the rails do not come in direct contact with ground, and the return current will be practically confined to the running tracks. If, however, the running tracks are laid below ground so that the top of the rails is on the level of the surface of the street, as is common in cities, then the rails will be exposed for a considerable area to contact with soil. If the tracks are laid on a concrete base a considerable area of the rails will similarly be in contact with the concrete. Since both damp soil and damp concrete are under ordinary conditions conductors of electricity, part of the current returning through the rails will shunt from the rails through the surrounding soil, as is illustrated diagrammatically in Fig. 2. It will be seen that, with the usual connection of positive terminal of the generator to the trolley wire and the negative terminal to the rails near the power station, the current will leave the rails for ground at points distant from the power station, and return to the rails in the neighborhood of the power station, in its path back to the negative terminal of the generator. Since every electric circuit must be completely closed, all current escaping through ground must again leave ground to return to the dynamo so as to complete the electric circuit. When underground metallic structures, such as gas or water pipes, lie in ground in the path of these stray currents, and where these pipes have electrically conducting joints, such as lead-calked joints or screw coupling joints, current will flow from ground to such pipes and flow largely on such pipes in a direction towards the power station. In the neighborhood of the power station this current will leave the pipes to return to the negative terminal of the generator, as shown in Fig. 2.

In the negative terminal of the generator or negative bus-bar is connected to the rails, at points some distant from the power station by means of insulated negative return feeders, then, at such connection points, the rails will be rendered negative in potential to ground, and currents will tend to flow from underground pipes through ground to return to the rails in the neighborhood of these connections. Stray railway currents on pipes will, therefore, tend to leave these pipes to return to the rails in all regions where these rails are connected to return feeders.

It must be noted that, while ordinary soil is a conductor of electricity, compared with metals its electrical resistance is enormously high; for instance, the resistance between the opposite faces of a foot cube of ordinary soil may measure anywhere from 10 to 1,000 ohms, depending upon the amount

of moisture and the amount of salts in the soil, while the resistance of a foot cube of iron is equal to about 0.0000004 ohms for the resistance of a foot cube of soil, it is seen that soil has no resistance which is of the order of 250,000,000 times as great as a body of iron of the same dimensions; that is to say, the conductivity of iron is 250,000,000 times as good as ordinary soil. It would seem from this that current would flow almost entirely on the good conducting rails and none through the high resistance ground. Resistance, however, varies directly as the length and inversely as the cross-section of a conductor, and with the large surface of rails exposed to the ground, the cross-section of the path of the current through ground is enormously great compared with the cross-section of the path of the current through the rails. As a matter of practice it is found that where the rails alone are used for the return of current, frequently a considerable portion of the total current actually leaks from rails through ground.

From the above considerations it will be seen that the leaking of current from the rails of electric railways, producing stray currents through ground and on underground piping, does not constitute a source of loss to the railway company; as, for instance, would be the case with leakage of gas or water. On the contrary, by allowing the current to return by ground and underground pipes as well as by the trolley cars back to the power station produces in these rails a drop in potential; that is to say, points in the rails away from the power station have a positive potential with reference to the rails at the power station. Since potentials are measured relatively it is convenient to consider the negative terminal of the dynamo, which is assumed connected to the rails at the power station, as at zero potential. The distribution of potentials in the rails of a simple electric railway system, and in the underground piping, is illustrated in Fig. 2, in which convenient values have been assumed. It will be noted that the stray current causes the underground pipes to be negative to the rails at points away from the power station, and positive to the rails near the power station. It is also seen that the negative potential of the pipe, plus the drop on the pipe, plus the positive potential of the pipe, equals the drop in the rails. In the case assumed a potential difference of 550 volts is maintained at the power station; of this, 10 volts is lost in the trolley wire, 520 volts is used by the motors of the cars, and 20 volts is left to bring the current back to the power station. If the negative bus-bar and the rails at the power station are considered as at zero potential, the rails at the car in the assumed case will have a potential of + 20 volts. Thus, for practical purposes, the ground with its underground pipes is subjected to a potential difference of 20 volts, and the amount of stray cur-

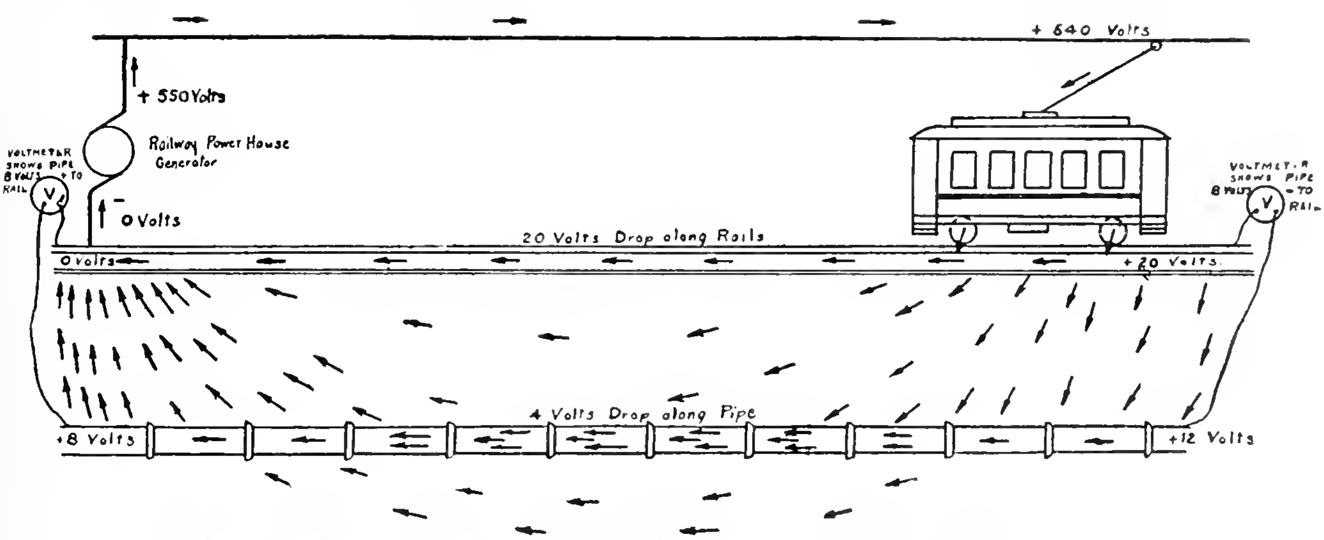

Fig. 2.—Diagram Showing Stray Currents and Assumed Resulting Potentials.

way of the rails, the total conductivity of the return circuit is increased, and the voltage loss in the return of this current is decreased, so that there is an actual saving of power for the railway company.

During the last few years alternating current has also been used in a number of cases for electric railways which employ the running tracks as a return conductor. Where these rails are in contact with ground stray alternating currents through ground are undoubtedly produced. As already pointed out, such alternating currents may produce electrolysis which varies up to 1 per cent. of that which would be produced by a corresponding direct current. However, no actual case of electrolysis from alternating currents from such railways has been reported, as far as the writer is aware. This may be due to the fact that alternating current electric railways in nearly all cases operate on long distance lines and on their own right-of-way, where they are away from underground piping networks. The author, therefore, does not feel warranted in drawing any positive conclusion as to the positive danger from electrolysis caused by alternating current electric railways where they operate within city limits.

General Effects of Stray Electric Currents on Underground Piping.—The current flowing through the rails from

rent produced is that due to these 20 volts. If the rails are laid in the usual way—that is, in contact with ground—the 20 volts in the rails will send some shunting current through the ground and through the underground pipe as shown in the diagram. Under the assumed conditions, there is a drop of 8 volts from the rails to the pipe near the car, a drop of 4 volts in the pipe itself, and a drop of 8 volts from the pipe through ground to the rails at the power station. It is, therefore, seen that it is the potential difference or drop in grounded rails caused by the return current which is the cause of stray currents through ground. Attempts should, therefore, be made to keep the potential difference or drop in rails as low as practicable, in order to keep stray currents through ground down to a minimum.

From the explanation of metallic and electrolytic conduction given in the first part of the paper, it will be understood that, where stray currents flow on underground pipes, they do no harm, except where they leave the pipes to flow to the surrounding soil. At such points corrosion of the iron from electrolysis will take place, and theoretically there will be a loss of 20 pounds of iron per year for every ampere of electric current leaving the iron. Some have assumed that, with the low densities at which current generally leaves un-

derground pipes, little or no corrosion is produced. A number of experiments made by the writer have clearly shown, however, that, even when current leaves iron for street soil at an extremely low density, corrosion is produced which is at least equal to, and frequently greater than, the theoretical amount. This increase of the actual over the theoretical amount is undoubtedly due to secondary chemical reactions set up by the action of electrolysis.

The underground structures which are most likely to be subjected to destruction from electrolysis, caused by stray electric currents, are piping systems and lead cable systems. From what has been said above it will be seen that oxidation or corrosion of such pipes or cable sheaths will occur wherever current leaves the pipe or cable sheath for ground. In the simplest case, illustrated in Fig. 2, current flows from rails through ground to the pipes at points distant from the power station, flows along the pipes and leaves the pipes to return through ground to the rails in the neighborhood of the power station. Where the current flows from the rails to ground the rails will be corroded, and where the current flows from the pipes to ground the pipes will be corroded. If the pipe line is a uniform electrical conductor, and the relative arrangements are as shown in Fig. 2, then the pipes will be corroded only in the neighborhood of the power station. If however, the pipe line is not a uniform conductor, as, for instance, if there are one or more high resistance joints in such pipe line, then the current on the pipe will shunt around these high resistance joints to produce oxidation or corrosion on one side of the joint. This action gives rise to joint corrosion, which is frequently found. Where there are two or more underground piping systems it also frequently happens that current shunts from one piping system to another through the intervening soil, producing electrolytic corrosion where the current leaves the pipe. Such shunting currents are often caused by accidental high resistance joints in one of the pipe lines, and such shunting may occur anywhere and without reference to the location of the railway power station. Where a direct-current trolley railway system passes through a town which has an independent piping network, and where the power station supplying the trolley line is in some other locality, then if stray electric currents are produced from the trolley line where it passes through the town, they will flow on the piping system, making this piping system positive to ground and to rails in the direction towards the railway power station and negative in the direction away from the railway power station. In this case electrolysis of the piping will be produced at the ends of the piping system towards the railway power station.

Where current leaves a wrought iron or steel pipe for ground, the oxide of iron resulting from electrolysis is diffused through the soil, and streaks of iron oxide can generally be found in the surrounding soil. Electrolysis of wrought iron or steel pipes usually results in pits, which eventually go entirely through the wall of the pipe. It has frequently been found in practice in the case of gas pipes that where a service of pipe lies in clay or other tightly packed soil, it may be pitted through in many places without giving any external sign of leakage, because the soil surrounding the pipe maintains it gas tight. When cast iron is corroded by electrolysis, the oxide of iron mixed with graphite usually remain in place leaving the outside appearance of the pipe unchanged. This material resulting from electrolysis of cast iron usually has the consistency of hard graphite, and can be cut with an ordinary knife. There have been many cases in which a cast iron main was carrying gas or water without any apparent leak, where a single blow with a hammer drove a hole right through the pipe. Here the electrolytic action had corroded the iron entirely through the pipe, and the oxide of iron had remained in place, and, together with the surrounding soil, had prevented the pipe from leaking. Whether or not the mixture of iron oxide and graphite resulting from electrolysis remains in place so as to maintain a pipe gas or water tight, depends upon the surrounding soil conditions. It is, therefore, seen that an underground piping system may be suffering severely from electrolysis without having given any outward sign of the damage. A physical examination with a test hammer is required in the case of cast iron piping to establish definitely whether or not it has been damaged by electrolysis.

For a given current leaving an iron pipe, there is practically no difference in the amount of iron destroyed between cast iron, wrought iron and steel The electrical resistivity of cast iron is, however, about 10 times as great as that of wrought iron or steel, and the usual lead joints in cast iron pipes also have a resistance many times greater than the screw-coupling joints usual with wrought iron and steel pipes. For these reasons a given voltabe drop through ground will cause a much smaller current to flow on a cast iron pipe than on a wrought iron or steel pipe, thus practically making cast iron pipes much less subject to electrolysis than wrought iron or steel pipes. The most frequent damage from electrolysis is found in the case of service pipes where these cross under trolley rails or other underground conductors to which they are positive. Examples of destruction of pipes by electrolysis which are often found in practice will be taken up later under the heading of "Damage and Danger Produced by Stray Electric Currents on Underground Piping."

(To be continued.)

RADIATION IN HOUSE HEATING.

By C. F. Smith.

For those interested in estimating the required radiation for residences the following formula and tables presented in an article in The National Builder should prove of value.

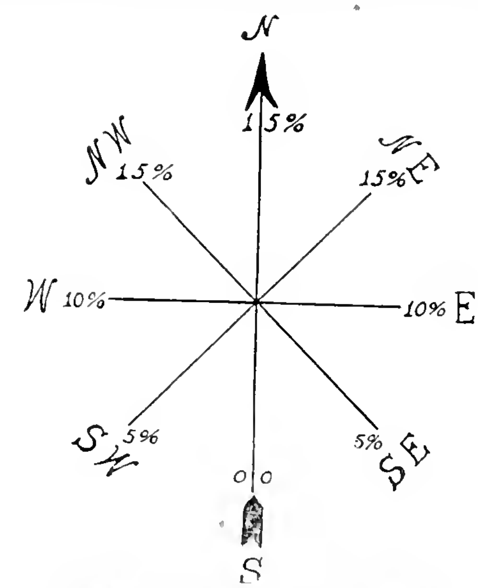

Diagram of Heat Units to be added for Different Exposures.

The formula is based on one change of air per hour in living rooms and bed rooms and three changes per hour in halls. In large living rooms or parlors, two air changes per hour, he states, should be provided for. Mr. Smith's formula is as follows:—

B.T.U. required $= W \times K + G \times L + C \times N \times T +$ a certain percentage for exposure in accordance with the following diagram.

In the formula:

W = net wall area.

K = a constant for different forms of wall construction in accordance with Table 1.

TABLE 1 (K)

G = glass surface (full size of window openings).

L = a constant in accordance with Table 2.

C = cubic contents of room.

N = number of air changes per hour.

T = a constant in accordance with Table 3.

If there is a cold space above or below the room, the surface area of the ceiling, or floor, should be multiplied by the constant R or S, as the case may be, as per Table 4, and the quotient added to the previous total.

EDMONTON TELEPHONES.

The city of Edmonton, Alberta, will spend in the neighborhood of $1,000,000 on extension work during 1913, the greater part of which will be cable work. It is the intention of this municipal department to build much underground conduit in both South Edmonton and North Edmonton, and there will also be considerable underground and aerial cable work. W. R. Griffith is superintendent of the department.

ENGINEERS AND GEOLOGISTS.

We take pleasure in publishing that portion of an address dealing with the general engineering profession, presented by Prof. H. E. T. Haultain, C.E., M.I.M.M., Professor of Mining, University of Toronto, before the recent annual meeting of the Canadian Mining Institute. It has caused considerable discussion, and as we mention, does not solely concern mining engineers, but applies generally. We are very sure every engineer will be glad to see Prof. Haultain taking up the gloves in an endeavor to give engineers who carry on material construction rather than interpretative theory, the credit that is due them. Quoting from this paper it states:—

There is another phase upon which I must touch, and that is the relation of the geologist to the community. Not only have the three last presidents of the Canadian Mining Institute been geologists, but the president of the American Institute of Mining Engineers is a geologist, the Dean of the Faculty of Applied Science of McGill is a geologist, the late renowned Principal of McGill was a geologist. Van Hise is president of the University of Wisconsin and Geikie is president of the Royal Society. We find geologists holding important public positions in all parts of the world, and holding them successfully and with distinction. The geologists are an ancient and honorable body. I can find no reference of slur or suspicion remaining attached to them. They have been clean and kindly men. Taking the geolgoists that I know personally I find them delightful men, agreeable companions and general favorites wherever they go. Of course, there is always the exception that proves the rule, but I believe you will all agree with me when I say that in general pleasantness the average of the geologists is higher than the average of most of the other groups of men with whom we come in daily contact. They are not only prominent in their scientific work, but they are prominent in the community, and the Canadian public at large accepts them not only as being of great importance to the State scientifically, but as being above the average good citizens.

In remarkable contrast to these public successes of the geologist, I find the condition of the engineer, not only the mining engineer, but the engineer in all branches. The engineer is doing the world's best work to-day. All that counts for prosperity and health and material growth is based on the work of the engineer. All that we are most proud of in this young nation is dependent upon the work of the engineer. The engineer exists in large numbers. Even in Ottawa there are more engineers than geologists. But we find very little public recognition of the engineer. We seldom if ever find him holding a public position of responsibility or honor outside of his immediate work. We have no engineers in Canada who are members of the Royal Society, and if we have one who has been knighted it is simply the exception that proves the rule. Why? How is it that the geologists beat the engineers to the high positions? Is it because their work is of greater importance to the State? Is it because their work is of a higher type? One would think so from the results. Is it not patent? Is it not obvious? But unfortunately the truth is not always obvious. Truth is oftener at the bottom of the well than prominent on the horizon. We must carry our analysis further. I submit that there is another and simpler reason. When we analyze the work and effort of the geologist we find it made up of two separate and distinct functions. The engineer's time and effort is devoted entirely to his engineering work. A part only of the geologist's time is devoted to the study of geology. A large part, and sometimes the larger part, is devoted to descriptions of his work, to publicity. One of their functions is that of the story-teller. From the beginnings of their existence they have been great story-tellers.

In fact, they have been the champion story-tellers of all time. Now, there is no doubt in my mind that some geologists, or near-geologists, will consider that this is another half-brick in poor disguise. But let us see what the story-teller has been to the community. When we go back to the beginning of things, that is, to the beginning of things for man, to about the time, let us say, of pithecanthropus erectus, the story-teller was beginning. He was almost the first luxury. Possibly man's first distinction was that he was a fire-using animal. Certainly about the same stage of his development he became a story-telling and a story-hearing animal, and the story-telling part was certainly more removed from mere animal than any other phase of his activities. Progress in all stages has been based largely on co-operative organization, and this came first with the fighting animal, but organization alone did not win out from the animal stage. Organization could, and does, exist without language and without man, but we departed from the animal through language and progressed through language. Language was produced by and for the story-teller. For his purpose was language developed, and without language we would have had no modern man. The neolithic scriber on bone, that "mamothistic etcher at Grenelle," was a later development of the story-teller, who told stories in pictures, and was not only the forerunner of the comic supplement, but of all that we understand in modern pictorial art. Later, he told stories in song and in mimicry, so that all our art, which represents our greatest departure from the anthropoid ape, is the work of the story-teller. He has been in the vanguard of all progress since we left the trees.

It is impossible to conceive of a geologist being eminent without this story-telling function being well developed. Unlike most story-tellers, he generally tells his own story of his own work. He is his own publicity agent; and what magnificent stories he has been able to unfold. In the second chapter of Genesis, and the second verse, we are told that God rested on the seventh day, and for a thousand years man had interrupted all his work every seventh day to signify his assent to the six-day history of the world's creation. The story-telling geologist comes along and says: "There is a mistake somewhere; it took several million years to create this earth, and I can prove it. Here are the proofs." When the world had become accustomed to the shock of this, the geologist's story went on to tell that man was not created on the sixth day, but that his creation was a gradual development occupying a period also of millions of years, the records of which in an almost unbroken chain stretching from the protozoa to modern man are preserved in the everlasting rocks. True, some links were absent, but every now and then the story is added to and the Neanderthal skull and our friend from Java help to fill in the blanks. Who couldn't attract attention and hold the stage with such stories as these? And the geologist had many such in his bag. He shows us where the moon was born. He dissects the teeth of the mammoth who wandered in our back yard before the ice was two miles thick upon it, and he counts the nervatures of the wing of the fly that plagued it.

But even the geologist's supply of stories could not keep up forever to these high-grade samples, and, as the family of geologists grew, they had to be content with less and less interesting stories. But stories they must have to maintain their eminence, and a story, to be a story, entails of necessity a hearer, a willing and an interested listener. As the quality of his stories waned he often had to expend as much pains finding the listeners as in finding the story, and this led him to the study of the listener, to the study of man, his characteristics, his wants, his needs, his foibles, and his weaknesses. He had to make the most of meagre stories, he had to study that phase of man which brought him listeners. This has been going on for generations, and the methods of the family of geologists in finding hearers is as well organized to-day as their study of geology. Are not many of them geologists in the summer and writers of their stories in the winter?

Now the story-teller is still the greatest man among us. What does Kipling get per word? and has he not had the refusal of the high honors of the realm? Theodore Roosevelt received $350,000 for seven years' work as President of the United States, but received a million dollars for the story of his African holiday. But the geologists' stock of interesting stories is running low, or rather the proportion of interesting stories to the number of geologists is becoming small, and instead of a greedily paying public he must perforce fall back on government bluebooks for publication.

And how do I interpret all this? I interpret it thuswise. The work of the geologist is in two parts. There is the study of geology to get the story and of man to get a listener. The engineer is so busy with his own work that he fails to study man. The geologist, with his knowledge of man and with his knowledge of publicity becomes useful to man in other ways.

The search for a listener has made the geologist in many ways a broader and a bigger man, and his art of story-telling brings him into the public eye.

Do I begrudge the honors to the geologist who has reached to high position through his knowledge of man? By no manner of means. I respect him, in some cases I bow down to him, but let us be honest about it and recognize that it is not the geology, but the story-telling and the man that has won to high honor.

Why, then, my half-brick of last year? It was not directed at the geologist as a geologist or as a story-teller but at men who were inclined to tell stories of no consequence to listeners provided by the reputation of the whole family of geologists, and to make capital out of these stories of no consequence. The geologist has from time immemorial been on a pedestal, and has, no doubt, taken care to be kept there. Round and about him, due to his art of story-telling, there has been a halo or an aura. His stories have not only had the important essentials of mystery and distance, but, in the main, they have been truthful and unquestioned by the general public. But there are those who would impose on this good name and on this long-earned and carefully preserved reputation.

I must confess that it is a source of some content to see the radical change that has taken place in our programme since last year, with the greatly reduced percentage of geological papers. There are many geological stories that we require, but that fact need not be abused.

This summer the geologists from all the world are coming here, and they will bring with them their best stories, and we, aided by government grants, have been diligently preparing for them, not only to hear their stories, but to provide them with new stories.

Their stories will be listened to by all manner of people, but by no one will they be more appreciated than by the mining engineer, for he will know and will preserve what he needs, and this he will use in practical work for the benefit of the community, and, going his own way, he will hold his peace and be unrecognized, and to the geologist and to the story-teller will be the glory.

The Grand Trunk Railway Company reports that during February it received on outstanding orders 428 box cars from the Pressed Steel Car Company, twenty-five box cars from the Canadian Car and Foundry Company; twenty-four Pacific type locomotives from the Montreal Locomotive Works; nine switch engines from the Canadian Locomotive Company; seventeen Mikado locomotives from the American Locomotive Company, and four refrigerator cars from the Canadian Car and Foundry Company.

RAILWAYS REQUIRED THIRTEEN MILLION TIES

There were 13,683,700 cross-ties purchased in Canada in one year. This in an increase of 4,469,808, or 48.5 per cent. over previous years. The increase is due largely to railway construction, which was specially noticeable in the Western provinces on the new transcontinental lines. The replacement of ties on existing lines amounted to about 10,000,000.

There were in all eighteen kinds of wood reported for cross-ties in 1911. Red pine, Western cedar, birch, maple, beech, poplar, Southern pine, elm and black ash were reported and classified separately for the first time.

Jack pine replaced cedar at the head of the list and formed about 40 per cent. of the total. The quality of available jack pine and its wide distribution were probably responsible for its popularity. Tamarack moved up from fifth to second place and formed over 19 per cent. of the total.

Douglas fir increased from 9 per cent. in 1910 to 14 per cent. in 1911 and moved up from fourth to third on the list. Hemlock fell back and formed only 12 per cent. The new railway lines are building north of the northern range of this species. Spruce increased from 2.5 to 6.6 per cent. on account of the same activity of railway building in the northern regions of the country.

Cedar took an abrupt fall from first place on the list in 1910 to sixth in 1911. Practically all the cedar reported is Eastern cedar, as the Western species is too soft for satisfactory use for cross-ties. The supply of Eastern cedar of either tie or pole size is practically exhausted. These six species together form 97 per cent. of the total. The others in the list are used in small quantities only, and for particular uses.

The average price of ties in 1911 was 39 cents, one cent more than in 1910. Of the species used in quantity, oak ties at 81 cents were the most expensive, and spruce ties were the cheapest at 26 cents. Spruce, hemlock and cedar all show a decrease in average price while jack pine, tamarack, Douglas fir and oak all show an increase. The prices of other woods are not comparable as they are purchased in such small quantities.

About 63 per cent. of the ties purchased in 1911 were hewn. In 1910 about 70 per cent. were hewn, so the sawn tie is evidently increasing in favor, states a recent bulletin of the forestry branch compiled by Mr. R. G. Lewis, B.Sc.F. Douglas fir ties were 94 per cent. manufactured in this way. Oak chestnut and Southern pine ties were more than 50 per cent. sawn.

Jack pine, tamarack, hemlock and spruce were mostly hewn, while cedar ties were about half and half. All the poplar and red pine ties were hewn.

Sawn ties cost on the average 41 cents, or 4 cents more than hewn ties, while in 1910 the hewn ties were the more expensive by three cents.

The ties purchased by electric roads were 81 per cent. sawn as opposed to 35 per cent. in the case of steam railways.

In 1910 the electric roads used only 38.6 per cent. of their ties sawn and 61.4 hewn, so with these companies as well as with the steam railways the sawn tie increased in popularity.

Of the sawn ties Southern pine ties were the most expensive at $1.11, with oak next at 82 cents. The cheapest sawn ties were of birch, beech and maple at 23 cents. Of the hewn ties chestnut were the most expensive at 58 cents and birch, maple and beech the cheapest at 20 cents.

Steam railways in 1911 used 95 per cent. of all the ties purchased. They purchased, in 1911, 13,094,528 ties—an increase of 4,185,106, or 47 per cent. over 1910. This increase is due, as stated above, to the construction of the new transcontinental railways. They used all the ties made from Western tamarack, Larix occidentalis, Western cedar, Thuja plicata, birch, maple, beech, poplar, Southern pine, elm and black ash.

Electric railways used only 5 per cent. of the total number of ties purchased in 1911.

The electric railways' total of 589,242 is an increase of 95 per cent. over 1910. This increase is greatest with Douglas fir, the use of which has increased over sixfold. Douglas fir was not used for ties by any of the electric railways of Eastern Canada. Fir ties formed over half of the total number purchased; this species replaced cedar at the head of the list. The cost of 20 cents is below the average for all kinds of wood.

Cedar ties, which had hitherto headed the list, fell back to second place with 28 per cent., and these ties increased in price from 37 to 41 cents, a price above the general average, demonstrating the increasing scarcity of this material.

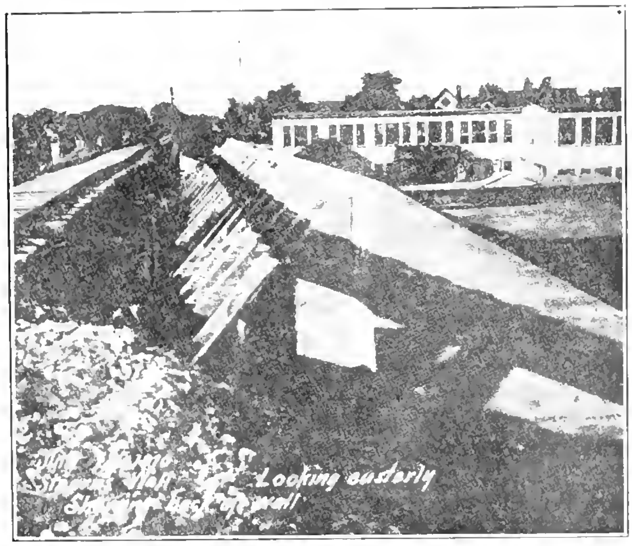
Tamarack shows an increase in number but a reduction in price. Tamarack is found in small isolated stands and its prices and quantities vary with the accessibility of the material to the railway line.

The average price of 29 cents per tie in all species used by electric railways is a reduction of 12 cents from 1910 and is due to the great reduction in the cost of Douglas fir ties, which form over half of the total. Electric railways got their ties 10 cents cheaper than steam railways. No red or white pine ties were used by electric railways in 1911.

REINFORCED CONCRETE RETAINING WALL.

An interesting article on a particular type of retaining wall appears in the last issue of The Cornell Civil Engineer. The author is engineer of grade elimination on the N.Y.C. & St. L. Railroad, and quoting from Mr. Himes' article on this subject he states:—

A wall of somewhat unusual design was constructed on the Nickel Plate in East Cleveland, in 1910. The purpose of



View Looking Eastward, Showing Back of Wall.

the wall was to permit the elevation of the N.Y.C. & St. L. tracks without encroaching upon the adjacent property. The owners of that property exhibited a very unfriendly spirit towards the railroad company, and it was deemed necessary to effect the elevation of the tracks without in any way encroaching upon the property.

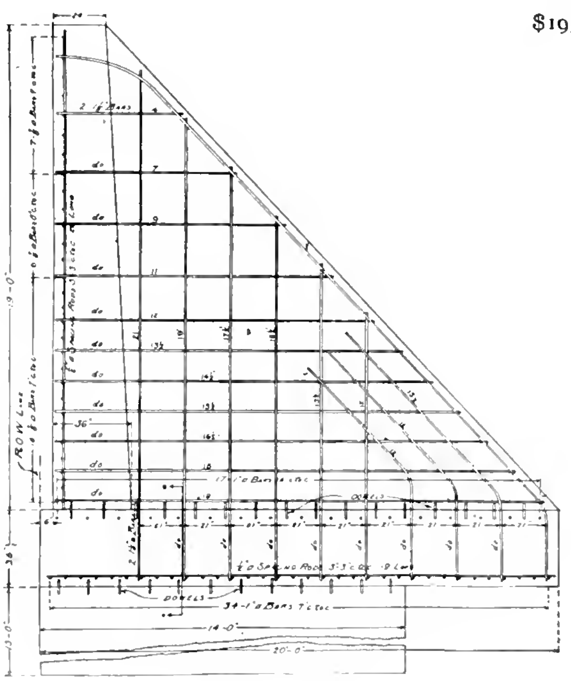
This made it necessary to carry the wall down to the rock surface, some 18 feet below the top of the ground. The centre line of the nearest railroad track was about 11 feet 6 inches from the face of the wall. The length of the wall was about 250 feet. A careful study of the problem was made and estimates prepared to show the comparative cost of a reinforced and a gravity wall.

The accompanying plans and the following tables show a full theoretical discussion of the subject and the final design, the formulæ of the American Railway Maintenance of Way Association being used.

Reinforced Counterfort Wall.

Loads per foot section.		C. of G. refer. to C tracks.	Moment.
Counterfort and main wall	30,320	5.4	183,700
Footing	9,000	2.5	22,500
Surcharge	9,600	0.0	00,000
Earth	20,790	—1.9	—39,500
Pier	30,000	5.5	165,000
Loads per foot of pier brought from intervening wall:—			
Main wall × 8/5...	6,400	11.0	70,400
Earth × 8/5.......	65,100	1.3	84,600
Footing × 8/5.....	14,400	5.5	79,200
Surcharge × 8/5 ..	15,400	0.0	00,000
	201,010		565,900

Item.	Quantity.	Unit price.	Cost.
Concrete (wall)	1,250 cu. yds.	$6.50	$ 8,125
Concrete (piers)	700 cu yds.	6.50	4,550
Excavation (wall)	40 cu. yds.	0.35	14
Excavation (piers)	1,125 cu. yds.	1.00	1,125
Steel	121,900 lbs.	0.025	3,050
Engineering & contingencies, 15%			2,530
			$19,394



Section C-D.

$X = 2.81$.

E = Thrust at pier;

E′ = Thrust brought to pier by intervening wall;

$E = .285 \times 36.5\ (36.5 + 20)\ 120 \div 2 = 35{,}280$ lbs.

$E' = .285 \times 22.25\ (22.25 + 20)\ 120 \times 8/5 \div 2 = 25{,}730$ lbs. per ft. of pier;

E acts at a height of $[(36.5)^2 + 3 \times 36.5 \times 10] \div [3 \times (36.5 + 20)] = 14'.26$

E′ acts at a height of $[(22.25)^2 + 3 \times 22.25 \times 10] \div [3 \times (22.25 + 20)] = 8'.84$

Taking bottom of footing at reference line,

Total horizontal thrust acts at a height of $(35{,}280 \times .01 + 25{,}730 \times 8.84) \div 61{,}010 = 3'.75$

Resultant cuts the base 4′.2 from front of footing.

Toe pressure $= 2 \times 201{,}000 \div (3 \times 4.2) = 31{,}900$ lbs./sq. ft. = 222 lbs./sq. in.

Resultant of forces acting on wall proper cuts the top of the pier 8′.0 from the face.

Toe pressure $= (4 \times 14 - 6 \times 8)\ 171{,}010 \div (14)^2 = 6{,}980$ lbs./sq. ft. = 49 lbs./sq. in.

Heel pressure $= (6 \times 8 - 2 \times 14)\ 171{,}010 \div (14)^2 = 17{,}450$ lbs./sq. ft. = 121 lbs./sq. in.

E′ = 16,080 lbs. per foot of wall at bottom of footing.

Solid Wall.

Loads per foot section.		C. of G. refer. to C tracks.	Moment.

Item	Quantity.	Unit price.	Cost.
Concrete (wall)	2,000 cu. yds.	$6.50	$13,000
Concrete (piers)	1,000 cu. yds.	6.50	6,500
Excavation (walls)	40 cu. yds.	0.35	14
Excavation (piers)	2,020 cu. yds.	1.00	2,020
Engineering & contingencies, 15%			3,230
			$24,764

E = Same as for counterfort wall = 35,280 lbs.

$E' = 285\ (22.25 \times 42.25) \times \frac{1}{2} \times 120 \times 12/8 = 24{,}120$ lbs.

Total horizontal thrust acts at a height of $[(35{,}280 \times .01) + (24{,}120 \times 8.84)] \div 59{,}400 = 3'.59$

Resultant cuts the base 4′.3 from front of footing.

Toe pressure $= 2 \times 198{,}900 \div (3 \times 4.3) = 30{,}837$ lbs./sq. ft. = 214 lbs./sq. in.

Resultant of forces acting on wall proper cuts the top of the pier 6′.5 from the face.

Toe pressure $(4 \times 16.5 - 6 \times 6.5)\ 147{,}500 \div (16.5)^2 = 14{,}628$ lbs./sq. ft. = 102 lbs./sq. in.

Heel pressure $(6 \times 6.5 - 2 \times 16.5)\ 147{,}500 \div (16.5)^2 = 3{,}250$ lbs./sq. ft. = 23 lbs./sq. in.

The estimated cost of the wall as finally designed was $23,570, and the actual cost after writing up the accounts was found to be $21,342.20. The estimated saving over the cost of a gravity wall was about 20%. The wall was constructed with the forces of the Grade Elimination Department, not by contract.

A feature of special interest in the wall is the manner in which the load was distributed, so as to prevent the maximum pressure from occurring at the toe of the wall on the top of the pier. Theoretically the maximum toe pressure occurs in the face of the wall at the rock surface, but since the ground surface is near the top of the piers, it is probable that the maximum toe pressure at the rock surface is somewhat less than calculated. The face of the piers was built exactly on the property line. The face of the wall was set back 6 inches, in order to insure that no part of it would by mischance en-

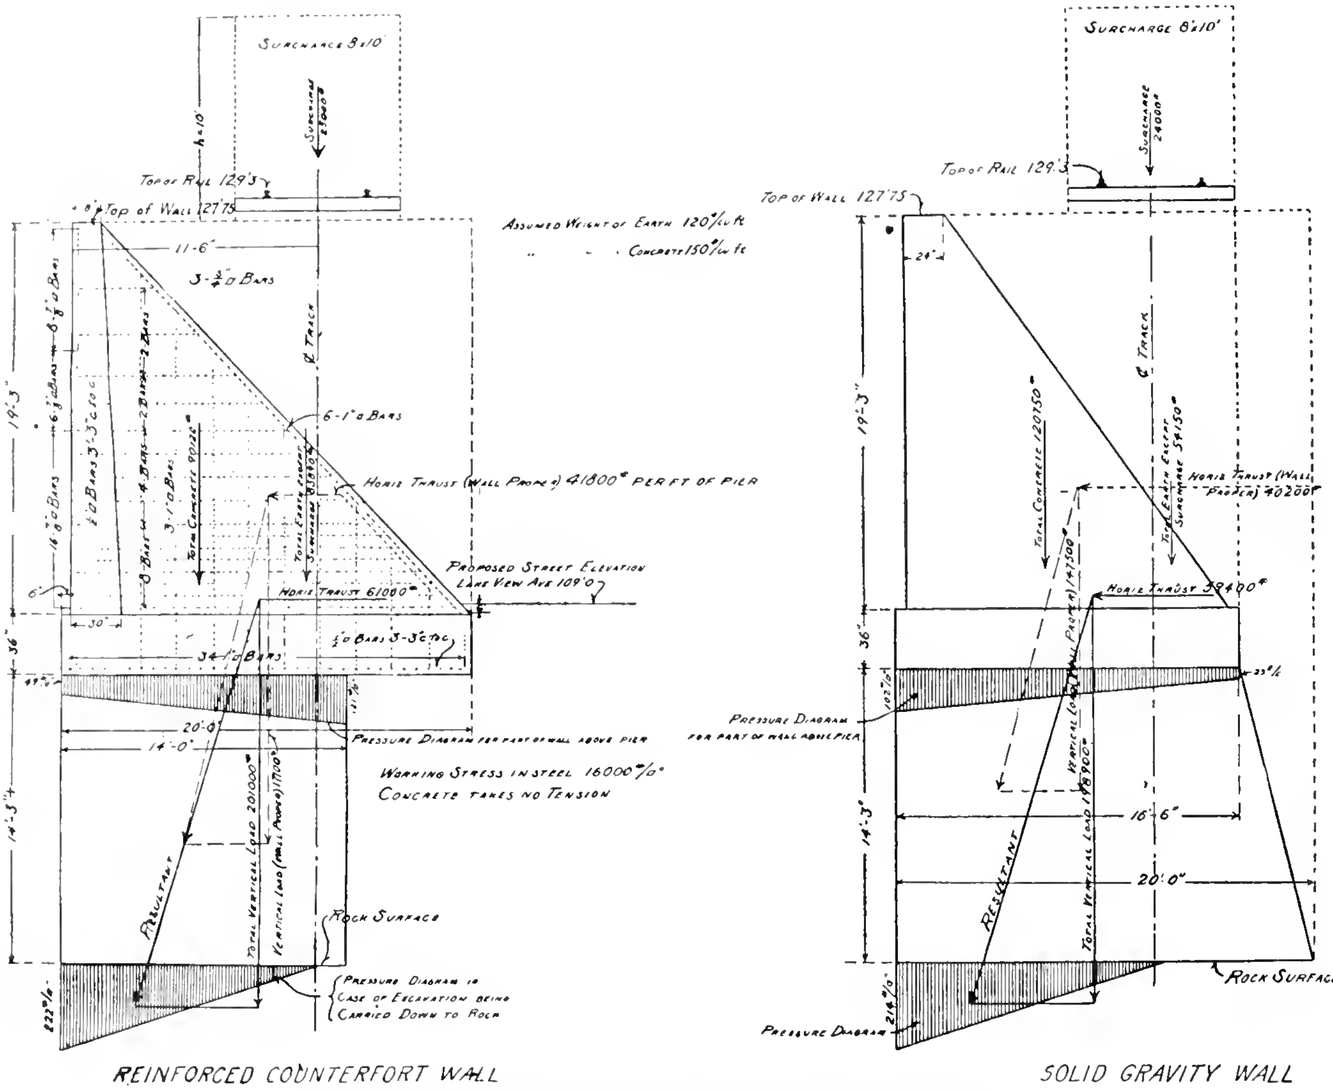
croach on private property. The wall has now been two years in service and no change of any kind has yet occurred.

The accompanying pictures illustrate the methods employed in its construction. At the street, abutments were constructed for the bridge over the highway. These abutments have no physical connection with the wall, being stalled and the joint so arranged that should either wall be inclined to tilt forward it would receive support from the other. Two-inch stone was used in the construction of the wall. It was found that because of the closeness of the reinforcing bars it was difficult to get the coarse concrete material in place. The use of smaller stone or gravel would



NOTE.—It is a condition of the design of wall that it shall be so constructed as to be perfectly stable in the event of the removal of all material above rock surface immediately in front of wall.

Comparative Designs and Estimates for Proposed Retaining Wall.

separated with carefully constructed joints. The several sections of the wall, A, B, C, D, were likewise separated by expansion joints. All of these joints have opened a trifle during the winters. A joint at the juncture of the main wall and the wing wall was located so as to bisect the angle between the walls. This location is always a plane of weakness and subject to cracks. In this case the crack was fore- have secured somewhat better results and cost less money. Quicksand was encountered in the foundations, but occasioned no serious difficulty beyond the settlement of the temporary trestle, from which the material was handled.

The details of the wall and the calculations were worked out by Mr. A. C. Irwin, formerly Professor H. S. Jacoby's assistant.

BRITISH LOCOMOTIVE CONSTRUCTION.

A mammoth new locomotive, 63 ft. 4¾ in. in length, weighing 116 tons, has been constructed by the London and North-Western Railway Company, and named "Sir Gilbert Claughton," in compliment to the chairman of the company. Having given full satisfaction on its trial, the new engine is regarded as the first of a practically new type of London and North-Western locomotives. It is a four-cylinder engine, the boiler is 5 ft. 2 in. in diameter and 14 ft. 6 in. long, and the three great coupled wheels on either side have a diameter of 6 ft. 9 in.

The construction of the new engine is a sequel to the interesting exchange of locomotives for trial purposes which was carried out between the North-Western and the Great Western two years ago. The experiments were continued for a week, and the North-Western Company came to the conclusion that the four-cylinder engine used by the Great Western was suitable to the requirements of the North-Western road. One of the first official duties of the engine will be to take the King on a visit to the London and North-Western works.

CONTENTS OF THIS ISSUE.

WESTERN LIGNITE POSSIBILITIES.

Word comes from Manitoba that the experimental station of the Provincial Government at Estevan for investigating the commercial possibilities of lignite coal is now under construction. Professor Darling will be in charge of the station, and it is expected to prove as tests progress that the deposits of lignite coal of the Souris valley have potential values for power purposes important to the whole of the southern portion of the Province.

It is sincerely to be hoped that this experiment of the governments will prove all that they could wish for in the way of fuel possibilities. Water powers are neither so frequently available nor powerful when found in the comparatively level prairie provinces as in other parts of the Dominion. Any absence of a plentiful and cheap fuel supply will make industrial advancement still more difficult.

Events seem to be steadily pointing to the practical utilization in the middle west of lignite on a large scale. For several years past the United States Government has been carrying on tests of the fuel possibilities of Dakota lignites, etc., and tests showed that while the best coal produced .28 horse-power per hour under boiler, lignite when operated as a producer gas produced .30 horse-power per hour. It is difficult to make use of lignite profitably in its raw state, as the moisture amounts to about 40 per cent., and it slakes and disentegrates into small particles if allowed to weather for more than a few months. Briquetting has been tried successfully as an improvement on the raw lignite, and, while it about doubles the cost, the heating value is increased 50 per cent. and the moisture reduced to 20 per cent.

It is well known that the railways operating in that part of the middle west of the United States where coal is expensive and beds of lignite close at hand have been particularly active in investigating the commercial practicability of lignite for their use, and have apparently come to affirmative conclusions. With the aid of specially designed spark-arresters the Chicago and Northwestern in part use lignite, and the Oregon and Washington Railroad and Navigation Company have specially designed locomotives of the Mikado type using it as a fuel.

It is to be hoped from tests that the future serviceability of the deposits in the Canadian West prove encouraging and give an added stimulus to the progress of that great region.

ROAD DESIGN.

In all parts of the Dominion is heard the slogan of good roads. Counties are adopting modern methods of highway construction, and cities and towns are vieing with each other in their plans and preparations to out-do rivals by abolishing unsightly streets. Governments, both provincial and federal, are making appropriations of large sums for road construction, and everywhere there is unprecedented activity towards better highways.

It is a time to be wary. The basic principle of good road construction has not changed since the days of Macadam and Telfor, but, thanks to modern traffic requirements, there has been the evolving and trial of numerous types of road surface. Many of these have well-known advantages for particular kinds of traffic, but variety has brought us up against a varying design of road surfaces that only an accurate knowledge of traffic requirements can enable one to pass judgment upon satisfactorily.

Canadian engineers should go carefully in their design and specifications for road surface. There are

large expenditures involved, and it will be cause for great regret if in the enthusiasm and haste to build good roads economical design is faulty due to a lack of proper information on traffic requirements. In the design of country roads especially, the engineer is likely to encounter difficulties, and should have an accurate traffic census for reference. Fast automobile travel, heavy truck traffic (both horse and machine), the use of narrow and wide tires, all increase the problems, and have to be considered and fullest information obtained on same, if one is going to do himself justice. Almost of no less importance must be the ability to foresee the traffic that will take place after his design has been carried into effect.

Prof. Blanchard, of Columbia, makes a definite classification of the most essential information concerning traffic; to be used in judging the suitability of a constructed road for the traffic upon it; considered as a basis for future designs, and in deciding the character of design to be adopted for a new road surface. In the latter case estimates of future changes to be made.

"(1) Differentiation between horse-drawn vehicle traffic and motor car traffic.

"(2) Division of each of these classes of traffic into pleasure and commercial traffic.

"(3) Subdivision of commercial traffic into loaded and unloaded vehicles.

"(4) Determination of the weight per linear inch of width of tire of all types of commercial traffic.

"(5) Subdivision of the two classes of horse-drawn vehicle traffic, dependent upon the number of horses.

"(6) Subdivision of pleasure motor car traffic upon the basis of weight and speed, since, in many instances, the greatest damage to certain types of roads is caused by seven-seat touring cars, limousines or landaulets, travelling at speeds of 40 to 60 miles an hour.

"(7) Extraordinary character of local traffic; for example, traction engines hauling trailers, motor bus traffic, ice wagons, milk drays, etc.'

These points are further brought out by observation, as, for instance, the sharp calkes on horses' feet in winter often rapidly deteriorate what under other circumstances would be a perfectly serviceable road. They bear out the well-known truth that the amount and character of traffic are of the utmost importance to the life of the road. Accurate traffic data should be taken, both for the construction design and after building for purposes of reference and repair. It does not appear to be as thoroughly carried out as the importance warrants, and it is to be hoped the coming summer will see much useful data collected not only for present benefit but future usefulness.

SPRING FLOODS.

The past week has witnessed the occurrence of the most disastrous floods in the history of the United States. A combination of heavy spring rains and previously swollen rivers was the cause, and there is a regrettably long list of dead as the result. Ohio and Indiana have been the chief sufferers, and Dayton City, of the former State, a city of considerable manufacturing importance, was cut off from communication for days, and in great part entirely submerged by the Miami River. Events are too fresh in the reader's mind and were too fully published in the daily press to need description here, suffice that several tributary streams meet in the Miami River just above the city, and the confluence of their swollen waters, together with a broken dam, appear to have been the cause of the destruction. Throughout the above mentioned States record flood levels have been attained by many of the streams, and the destruction wrought and the number drowned is astonishing.

Such a catastrophe is horrible to consider, and, we believe, unnecessary of occurrence. Every spring we see damaging floods in the United States to the extent of millions of dollars worth of property. Some of that money spent in preventive measures would go a considerably long way towards controlling the floods, and should certainly be used to prevent an outrageous loss of life, such as in the present occurrence. Given the opportunity and money, and engineering ability can collect data and devise means to greatly control floods. If it is beyond finance and practicability to control them, engineers can at least point out the danger zones, and people should be forbidden to reside within them.

The deforesting that has taken place in the flood area is, without doubt, in a great measure responsible for the exceptional flood conditions, and makes it very plain that the United States Government will have to do something to offset the lessening of nature's storage reservoirs.

Canadian flood problems are small in comparison with our neighbors to the south, and, thanks to provision of nature, are likely to remain so. The Great Lakes, acting as storage reservoirs, rapidly drain and make any disastrous floods in the settled portions of Ontario impossible. Further back in the Laurentian Hills, even if deforested, numerous lakes would make storage provisions, with the help of dams, comparatively easy. The prairie provinces having been always comparatively bare of forests are not likely to incur any great increase of the flood heights to which they are accustomed.

Our general topography and lake systems leave us without such gigantic flood problems to struggle with as has the United States in the Mississippi Valley and its tributaries. Nevertheless, there are valuable lessons to be learned from a study of the recent catastrophe in Dayton, and, no doubt, our government will avail itself of the opportunity.

TELEPHONIC TRAIN CONTROL IN ENGLAND.

The first train-controlled system by means of the telephone in England has just been installed on one of the railways in Wales. The following description of the system recently appeared in a London journal:—

As the result of the installation of a system of telephones in all signal cabins, junctions, and stations on the line, the whole of the train working can be completely and directly controlled from the head office at Cardiff. The train controller in the general office can, by means of the telephone at the different points, know precisely the movements of all the trains, and is able to divert a train almost at a moment's notice.

It is believed that as a result of the new installation much time will be saved, and consequently that there will be quicker dispatch. It is anticipated that the new service will prove not only useful to the railway company, but also to the large number of collieries which are on the railway system and whose output forms such a large proportion of the traffic. By the telephone system as many as 45 stations may be connected to one pair of trunk wires, any one station of which may be rung up by the train controller without ringing the bell at any other station, and the controller can hear the bell ringing at the station called. On the other hand, if necessary, all of the stations on the system may be rung up at the same moment.

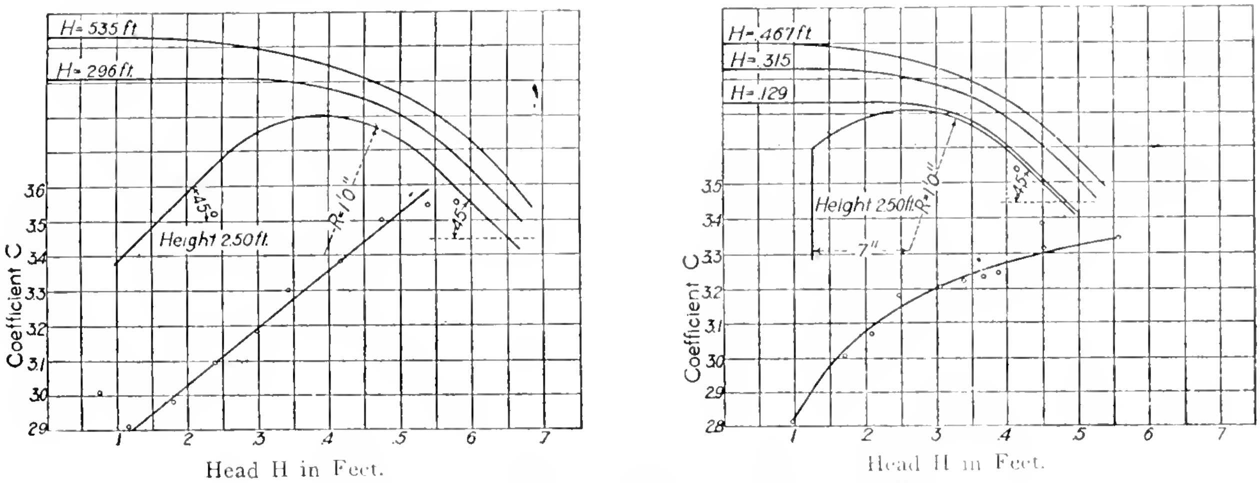
EXPERIMENTS ON FLOW OF WATER OVER MODEL DAMS.

A series of experiments to determine the flow of water, under low heads, over four models of dams was undertaken at the hydraulic laboratory of Purdue University as the graduation thesis of Messrs. Lane and Kemmerer. The investigation was carried out under the general direction of Prof. R. L. Sackett, who reported the results in a paper presented before the Indiana Engineering Society on Jan. 25.

The model dams were placed in a concrete channel 100 ft. long, 3 ft. wide, by 35 ft. deep. The length of crest was in each case the width of the channel. Discharges were measured with a Venturi meter; and the elevation of water surface was determined by a hook gauge.

The results obtained by Bazin, the U.S. Geological Survey, as given in Bulletin 200, and by Rafter and Williams in 1899 were compared and models selected which would add to the variety of sections and heads heretofore experimented with.

The first model was a flat crested weir 0.98 ft. wide and 2.38 ft. high. This is about the width of No. 47 of the U.S. Geological Survey experiments and between models No. 2 and No. 113 of Bazin's work. Results were plotted for Bazin's dam, 1,315 ft. wide, the U.S. Geological Survey dam, 0.927 ft. wide and the Purdue model No. 1 with a crest of 0.98 ft. wide. The form of the surface curve also was plotted from data taken on the checker-boarded vertical side-walls of the channel.



Surface Curves and Coefficients, Models 3 and 4.

The second model was the same as the U.S. Geological Survey No. 40, except that the height was 11.25 ft. in the latter and 2.27 ft. in the Purdue model. The results in both cases were plotted, and it is believed by Prof. Sackett that at low heads the data are of some value. The surface curves were plotted for three heads.

The effect of the partial vacuum formed below models 1 and 2 was very noticeable on the surface curve, but com-

Observed Flow Over Model Dams

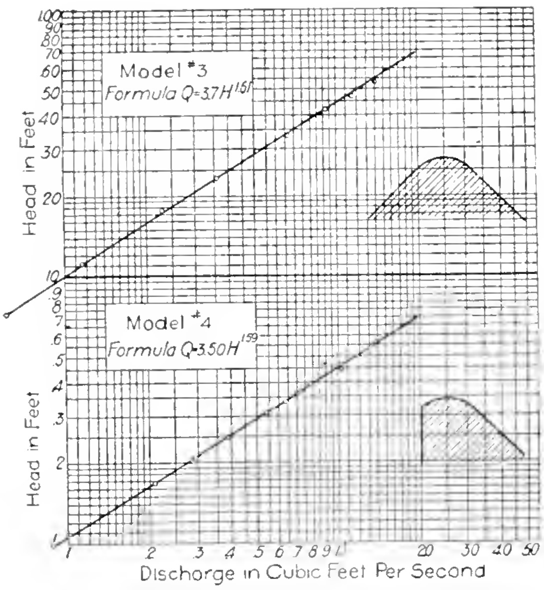
parative data with and without the vacuum were not taken. The results are with the nappe aerated—a fact which it is necessary to consider when comparisons are made.

Model 3 is similar in section to the hollow, buttressed type of concrete dam and model 4 is the same, with the sloping approach omitted. Model 4 is a small scale reproduction of the Yakima dam, and the surface over which the water rubbed was formed of cement mortar and closely resembled the troweled finish of concrete. It is similar in form to type L, page 73, of Williams and Hazen's Hydraulic Tables.



Discharge Curves, Models 3 and 4.

The coefficients for models 3 and 4 are nearly the same for heads of 0.1 and 0.3 ft., indicating that for such low heads the upstream slope has little effect on the coefficient. As the head increases the curve is a straight line for model 3, and curved for model 4, showing the effect of the sharp corner within the limits of the heads used.

The curves show the observed head on the crest and the coefficient C in the formula, $Q = CLH^{3/2}$.

The table shows also the constants C_1 and n in the formula $Q = C_1LH^n$, where H is the observed head plus the velocity head.

CONCRETE AND STEEL.

Building regulations of Greater New York require that in reinforced concrete the stresses in the concrete and steel shall not exceed the following limits:—

	Per sq. in.
Extreme fibre stress on concrete in compression ..	650 lbs.
Concrete in direct compression	500 lbs.
Shearing stress in concrete when all diagonal tension is resisted by steel	150 lbs.
Shearing stress in concrete when diagonal tension is not resisted by steel	40 lbs.
Bond stress between concrete and reinforcing bars	80 lbs.
Tensile stress in steel reinforcement............	16,000 lbs.
Tensile stress in cold drawn steel wire used as column hooping	20,000 lbs.

In continuous beams the extreme fibre stress on concrete in compression may be increased 15 per cent. adjacent to supports.

EXPLOSIVES.

By J. K. Moore.*

In nearly all kinds of construction work carried on by engineers, blasting and the use of explosives play a more or less important part. With the arrival of spring and the start of active construction, it would not be out of place to discuss different types of explosives, their most efficient use and details of the proper handling of same. Nearly all accidents occurring from explosives are through negligence or from ignorance, foolhardiness or carelessness, and it behoves all workers with same to be thoroughly posted on the subject.

Some high explosives have a powerful action over a small area, being instantaneous in combustion. Others not so powerful, but shake up a large mass. One will smash rocks to pieces, rendering them useless for building purposes, but suitable for loading for a steam shovel. Others just the opposite, explosion being prolonged and the action more of a push than a direct blow, thus leaving the rock almost free from fracture and suitable for dimension stones, etc.

You therefore see that all have their uses and should be used in their right places in order to get the best results.

If the rock is hard and solid and not wanted for building purposes, use a high explosive; it will do the work. But if the rock is for building purposes, or even macadam, use a milder quality; you will have the better results and get your stones almost free from powder flaws. If the rock is soft or medium, you will find a high explosive is too local, so you must use the third or lower grade of dynamite, 40 per cent., or if the rock is for building purposes you must use a still milder quality, such as black powder.

Mistakes are often made in regard to producing rock for macadam. If the rock is hard and flinty a high explosive breaks it into pieces like spallings, full of flaws, and the additional fracturing, after having been broken by a stone breaking machine, renders it unfit for heavy traffic becaus it grinds down too quickly. But if a milder explosive i used, the fracturing is reduced to a minimum and the lif of the macadam prolonged, in some cases, about four times.

I have seen this experiment tried with the two explosives, put through the same stone napping machine at different points where the traffic was almost equal, rolled in by a steam roller, dressed with half-inch chippings and sand from the same rock and finally rolled with water and well brushed, so as to produce a good surface.

The one produced with the low or mild explosive lasted just three times the one produced by the high explosive or dynamite, and as one road surveyor put it, was almost like machine broken metal and hand broken metal in comparison.

Drilling.—To prepare rocks for the explosives, drilling has to be done. There are various ways by hand, steam, compressed air, etc.

There are several methods of hand drilling, the auger or rotary drill for soft rock and coal, the hammer or jumper drill and the churn drill. The last two are more suitable for our purpose, where drilling is light, and as a rule we keep out of rock as much as possible in laying out a road.

The hammer or jumper drill is familiar to us all and it is maintained by many that one man can drill a hole to a depth of three feet cheaper than three can do, by using the hammer in one hand and turning the drill with the other. When the hole is well entered, a splasher is used on the

*Road Superintendent, Cariboo and Lillooet Districts, B.C.

drill and water is poured in the hole. The water makes drilling easier, as it keeps the bit of the drill cool and moistens the drillings, which, when dry, cushion the blow, thereby reducing the striking force on the rock. When the drillings get pasty and stick to the drill, more water is used, and so on, until cleaning is required. Cleaning is done with a cleaner, which has a spoon button on one end and an eye on the other. The eye is used to dry out the hole by using cotton, hay or other material. Another way to clean the hole is by using a loose clack or single-hinged valve, circle pump. The clack, or hinged valve, is inside the pump on the bottom end, and as you put it down the drill hole, on coming in contact with the drillings, the valve raises and fills the pump, and as you raise it again, the valve closes and you empty it, and so on.

Up to ten or twelve feet the hammer drill does well, but after that it becomes slow, the drill being heavy to handle, etc., so that it would be better to use a churn from there up to about twenty feet.

Springing.—Having the holes drilled and ready for the charge, we must proceed. Every miner and powderman knows the benefit of having as much as possible of the charge at the bottom of the drill hole, also the advantage of springing the holes several times to make room for the charge at the bottom. The downward force of explosives is surprising and the result for those who practice springing deep holes, or chambering, is marvelous.

Springing of rock is to open up the joints at the bottom more than to make a pot hole so as to get the charge well down. I have seen holes sprung about four times in the following way:

A line of six holes were drilled about twenty feet deep, about ten feet back from the face of the quarry and about twelve feet apart. The rock was igneous, blue whinstone or granite, and about thirty feet deep, so that you will notice the holes were about two-thirds the depth of the rock. The width of the first drill was two and three-quarters and the last about two inches.

If, in drilling, the drill sticks in a joint, steel chips should be used to fill the joint. I have found this excellent in labor saving, as a troublesome hole is a nuisance.

The springing was done with black powder, glazed, because the rock was for making building stones, kerb stones and setts. The holes were sprung separately and about ten pounds used first time in each, with no tamping and fired by battery. This was more to find out how firm the joints were at the bottom. The second charge was about double that amount which opened the joints a little. This was continued until the joints were wide enough to receive the whole charge. One was a little large and was taking more powder than it should, so a little water or oil was used to make the connection good between the charge and the bore hole where the wire fuse was. This is a common custom amongst quarrymen in these building stone quarries where gunpowder is used, but should only be used if you cannot otherwise catch your powder with the fuses.

The total charge was about 350 pounds of gunpowder and the result was first class, nearly 3,000 tons being displaced. If this had been in ordinary excavation, 40 per cent. dynamite would have done to spring the holes, and 60 per cent. dynamite for the main charge.

Chambering.—I have also placed charges in chambers, but they were small, because the amount of work was light. However, there are several ways of running them, in the form of a "T" or a "Y," etc., the main tunnel being straight and the length in accordance with the work to be done. The branches are where the powder is stored. The main thing in loading these chambers is to exclude the air, build the explosive up as closely as you can, and after you have put in your primers (two at least should be used) and wires, the chambers should be built up solid with cement and stone or brick as explosives will follow up the line of least resistance in nearly every case—then fire as any other shot. The result is fine if everything is well judged, but in rock for macadam or building purposes, unless the mine is small and the output large, it is not so good for the stone, because rock, as you will know, does not work so well after it has been exposed for a time to the weather, as it gets dry and the natural moisture, or life, in the rock gets burned out and a man can not produce as many building stones, nor a machine as much macadam. And, again, if practised near a roadway it is liable to close the road to traffic for some time. Yet, for railroad contractors, mine-owners, etc., it is very satisfactory and cheap.

The difference in explosive properties are—dynamite is instantaneous and powerful over a small area; Judson powder is progressive and not so powerful as dynamite; Black powder is slow and progressive by combustion, but about half the power of Judson powder.

Dynamite and Judson powder can not be exploded the same as Black powder, by a spark, but requires force or shock, like a blow from a sledge, so a detonator or cap has to be used. The same method has to be used for exploding all nitro-glycerine compounds.

Care must be exercised in the selection of detonators or caps. The stronger the caps the better, and the more certain of entire explosion.

Testing Dynamite.—If dynamite is hard and resists yielding to the pressure of the fingers, it is frozen. It should not feel greasy, nor should there be a trace of nitro-glycerine on the wrapping paper.

In order to find out whether dynamite leaks or not, place it on clean paper and leave it in a room to dry in about 60 degrees Fahrenheit and leave it for about eighteen hours. If, on examination, there is any oily discoloration on the paper the dynamite has leaked. The best quality of dynamite should not do this. Fusing and thawing several times tends to leakiness, therefore it should be avoided. Again, on examination, if the dynamite has a whitish crust it is no longer safe, because the whiteness means dampness, and the nitrate of soda has leaked out. If it shows greenish spots, it shows that the nitro-glycerine has started to decay and it is therefore very unsafe.

Dynamite freezes more easily than water. It is the nitroglycerine that freezes at from 42 to 46 degrees Fahrenheit, according to the character of the material in it. When frozen it is hard and can not be loaded very easily into drill holes, nor is it very easily exploded. Yet it has been proved that dynamite can be exploded when frozen, but it takes greater detonation, and some engineers say it has been proven to be more powerful when complete explosion takes place, but it is not advisable to try it and any one doing so is running a great risk.

Thawing Dynamite.—Dynamite must be thawed. In doing so a large proportion of accidents from explosives happen.

The following is a list of what should not be done to ensure safety of powderman and men working with him. Many of the following being done through ignorance, and a list of the same should be copied out and distributed, one to each foreman, and the powderman failing to follow these rules should be instantly dismissed or given other work.

1. Never allow dynamite to be placed in front of a fire to thaw.

2. Never allow dynamite to be placed on a stove or heated metal.

3. Never allow dynamite to be placed on hot stones or gravel, or sand.

4. Never allow dynamite to be placed near glass of any kind in direct sun's rays.

5. Never allow dynamite to be placed in a tin and thawed over a candle.

6. Never allow dynamite to be placed on end round a lamp or candle.

7. Never allow dynamite to be dipped in hot water to thaw it.

8. Never allow dynamite to be carried in men's pockets or breasts to thaw it.

9. Never allow dynamite to be placed in a blacksmith's hearth in the ashes.

10. Never allow dynamite to be placed on a shovel and held over a fire.

11. Never allow dynamite to be placed around or on a boiler.

12. Never allow dynamite to be placed around or on an electric globe.

13. Never allow your men to slit dynamite open with a knife when frozen.

14. Never allow dynamite to be thawed in a can or metal pot surrounded by a water jacket if the water is in any way connected with fire, nor rubbing it in the hands to hasten thawing.

No. 7.—Thawing in water is an exceptionally dangerous form, because the water becomes highly explosive from leakage and has been known to cause serious accidents.

No. 14 has caused many fatal accidents through the dynamite becoming overheated and the nitro-glycerine dropping on the hot metal.

Nos. 1, 3, 5, 6 and 7 are very common ways used for thawing dynamite amongst powdermen in this country, and even if you have been lucky enough not to have had an accident therefrom, that does not reduce the danger any.

There is only one perfectly safe way to thaw dynamite, and that is to put in a warm room at summer heat, covered up and kept as dark as possible, away from the direct sun's rays and allowed to thaw out.

There are two other comparatively safe methods. One is in fresh horse manure in a box built for the purpose, and the other, in a can or metal pot surrounded by a water jacket. In this latter case remember warning No. 14.

The very best way is to never allow it to freeze, if you can do so by placing it in a frost-proof magazine.

Familiarity breeds contempt even for dynamite, by some, and as dynamite can be alight and burn up under certain conditions, adds in a degree, to the careless handling of it.

Primers and Loading.—Warning—In loading dynamite in drill holes, etc., never use anything but wooden or copper rammers, wood is preferable. Never allow anyone to help you who is smoking, and do not smoke yourself. Never let the sticks of dynamite drop heavily down a deep drill hole, nor force it into too small a hole or aperture, nor strike hard when ramming it into place. Caps are set off by a spark from the fuses and they explode the dynamite. Never allow caps to be lying around you while loading, nor carry them in your pocket, as you are apt to drop and explode one. Also, never allow nitro-glycerine to get on the hands, as it is easily absorbed and causes bad headaches.

The best method to loan a hole or place a charge, is, slit the cartridge on two sides, let the contents slip down gently, then take your rammer and press it gently to place. Then take a second cartridge and repeat the above, and so on, until you are ready for the primer.

In making primers, use the best quality of detonators, or caps, and first quality safety fuses. Take the cap and see that there is no sawdust left on it, then take the fuses, cut off the end and see that the powder is exposed and dry, then enter it in the cap and press it up to the fulminate. Be sure this is done because shots often miss-fire through the fuse failing to set off the cap. If the fuse is larger than the cap, scrape it down to fit, only do not open the cap, then press or clamp the upper end of the cap to the fuse, being careful not to disturb the fulminate in the cap. Never clamp the cap on to the fuse with your teeth or fingers, but use nippers or pincers, a tool made for the purpose, which cuts the fuse and clamps the cap to the fuse.

If you are working in wet ground or rock, use lots of grease or soft soap around the joint you have thus made and see that your fuse is waterproof. Double or tape gutta-percha fuse is the safest in water. After the cap and fuse are ready, take a cartridge of dynamite, open one end and make a little hole with a pointed stick, then insert the cap and fuse and gather the end of the cartridge paper around the fuse and tie with a piece of cotton. If in water, grease the joint well, as previously mentioned, then place with the charge, placing one or two more cartridges on top.

Then tamp with fine clay or sand, putting in a little at a time, and at first pressing lightly. Be careful not to check the fuse or draw it away from the charge, and do not use anything but a wooden or copper tamper or rammer.

Use lots of stemming or tamping, always be on the safe side in a final charge, then cut off the part of the coil of fuse not wanted and place it on one side. Be sure you have sufficient fuse to allow everyone to get away. Accidents often happen through neglecting this point, and, after all, one foot of fuse does not cost very much.

Signals for Firing.—After everything is ready, clear away all your remaining explosives and tools to a safe place, and on return, shout "fire" or give other warning. Then when you see that every one has laid his tools safely to one side, give a second warning and split the end of your fuse, and before lighting, see that every one has gone, then light the fuse, give a third and final warning, and take shelter yourself.

Never use water for drinking purposes coming from rock or ground you have recently used dynamite in as it will cause sickness and headache. If several shots have to be set off at one time, use wind-proof fuse matches or a spitter, and, if matches, never allow one man to set off more than two or three shots. If more than that he should have a helper to light them, and remember, a flame will not light a fuse, it must be a spark.

To make a spitter, or touch, take about twelve to fifteen inches of fuse, cut into the powder every one and a half to two inches, then light, provided everything is ready and the warnings sounded, and hold it to each fuse in the shots. It will readily light, but I would not advise more than four or five shots to each man. In the smallest of shots be careful of your fuse and see that you leave sufficient length to give you time to get away. I would not recommend less than twelve or fifteen inches even if the fuse has been tested as to time.

Black Powder.—In charging holes with black powder never use an iron rammer, always use wood or copper. Never allow fire of any kind near the charge, and if loose, always use a zinc or copper can, or flask to carry it in. Use a zinc or copper filler when charging the hole, and if the hole is horizontal, or has an upward tendency and hard to load, use a copper tube made for the purpose. If the angle is too heavy, you may have to make a cartridge containing the amount of explosive required, with a fuse inserted. Upright or vertical holes are rarely used in road work.

(To be continued).

THEORY AND PRACTICE OF STADIA SURVEYING.

By J. A. MacDonald.

The credit of having first introduced this method of surveying into America belongs to Mr. John R. Mayer, a French-Swiss. It was used by him as early as 1850; and subsequently during his connection with the United States Lake Survey, he did much towards perfecting the instrument and improving the methods of work. An essay by him in the Journal Franklin Institute for January, 1865, contains a short historical sketch of the development of topographical surveying and brief discussion of the general principles of stadia measurements.

The many advantages of stadia measurements in surveying need not be dwelt upon, both because attention has been repeatedly called to them, and because they are self-vident to every engineer, so far that all instrument-makers now take especial precaution in fitting the telescopes of all good transits with carefully adjusted stadia hairs This paper will therefore dwell on the theory and practice with a view of encouraging the use of this simple, rapid and wonderfully accurate method of surveying in a larger degree than has been. Tests of correctness of stadia readings with a transit having fixed stadia hairs not properly adjusted to the unit 100, has prompted the following article.

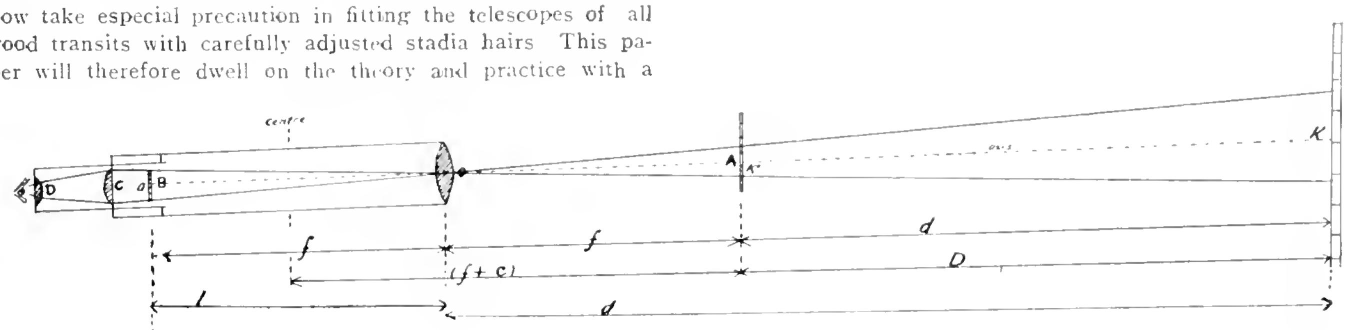


Fig. 1.

The Transit Telescope.—We find that according to the laws of optical science, an image, of any object to which the telescope may be directed, is formed within the tube, and there magnified by an eyeglass or eye pieces composed of several lenses. Any object is rendered visible by every point of it sending forth rays of light in every direction. Those rays of light coming from the object are bent in passing through the object glass. It is the law of light rays to move in a straight line when not obstructed. The best exposition of the relation of light to image is shown by the so-called pin-hole camera. There being no lens, there is no obstruction to the rays of light coming from the object photographed, and passing through the tiny pin-hole of the camera are therefore free from distortion, and are perfectly pictured on the negative, in an invented position, of course. Just as is the image passing through the object glass of a telescope, as the rays of light intercepting one foot on a rod, one hundred feet from the telescope, and passing through the object glass to the cross-hairs, are so nearly parallel, and come so near to each other that they are almost in line of colleimatem scarcely unaffected by the convexity of the object glass. For, by a principle of optics, the rays from any point of an object converge to a focus at such a position that a straight line, called a secondary axis, connecting the point with its image passes through the centre of the lens, and the point of intersection is called the optical centre. From this it follows that lines drawn from the stadia wires, through the centre of the object glass, will intersect the rod at points corresponding to those which the wires cut on the image of the rod (Fig. 1). On these underlying principles are based the law of stadia measurements.

Fig 1 represents a telescope which inserts the object. In the figure the highest and lowest points of the rod are intercepted by the stadia wires, are alone considered. The upper and lower rays shown, proceeding from the rod in meeting the object glass, O, form a cone. The longitudinal section appears only in the figure (Fig. 1). It will be seen that these rays, after passing through the object glass, cross one another and thus form, at B, an inverted image of the rod. The rays forming this image continue onward and pass through the two lenses C and D, which act like one magnifying glass, so that the rays, after being reflected by them, enter the eye at such angles as to form there a magnified and inverted image of the rod K. Fig. 2 represents a telescope which shows objects erect. Its eye pieces has four lenses. It will be seen that an inverted image of the arrow A is formed at B, as before, but the rays continuing onward are so refracted in passing through the lens, C, as to again cross, and after further refraction by the lenses D and E to form, at F, an erect image which is magnified by the lens G.

That shown, Fig. 1, which shows the object inverted, is preferred for stadia work. The erecting eye pieces absorb light and lessen the distinctness of vision. A little practice accustoms the observer to seeing his rod man standing on his head, without becoming alarmed, and to motion him to the right when he wishes him to go to the left and vice versa. What makes it difficult to understand the principles of stadia measurements is that the image of the rod, or any object, is not seen at the vertical position of the cross hairs at all; for the image of the cross hairs (and the rod intercepted by them) is optically projected beyond the objective to the extent of the focal length of the latter. The image of the cross hairs, at B, Fig. 1, is optically projected at A. The rays converge at that point, and measurements must naturally be taken from there.

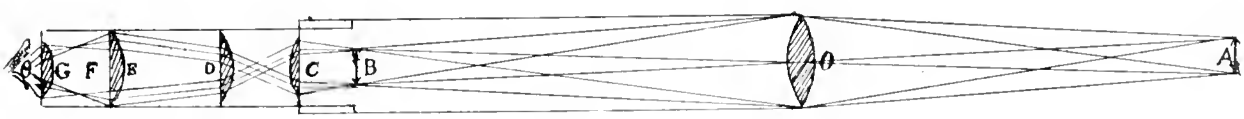

Fig. 2.

The Reduction of Stadia Notes.—For stadia measurements with inclined sights two methods of procedure are in use. One to hold the rod at right angles to the line of sight, the other to hold it vertical. With the first method it will be

seen by referring to Fig. 3 that the distance rod is not to the foot of the rod E, but to a point F' vertically under the point F, cut by the centre wire. A curveline has therefore to be made for this. An objection to this method is the difficulty of holding the rod at the same time in a vertical plane and inclined at an angle proportionate to the angle of elevation of the telescope. The method adopted usually is the oblique view of the rod:

Oblique View of the Rod, Investigated Trignometrically.

FIG. 4 a = distance of stadia wires apart.

f = principal focus of telescope.

$\frac{f}{a}$ = K^1 = constant, and generally made equal to 100.

A B = K the reading in the rod.

M F = d the inclined distance = $(f + c) + G\,F = (f + c) + K^1\,C\,D$.

M P = D, the horizontal distance, d cos. n.

F P = Q = the vertical distance, D tan n.

A G B = 2 m

Vertical angle = n

Then :—

$$\frac{A\,F}{G\,F} = \frac{\text{Sin } m}{\text{Sin } \left[90^\circ + (n - m)\right]}$$

or

$$A\,F = G\,F\ \text{Sin } m\ \frac{1}{\text{Cos } (n - m)}$$

and

$$\frac{B\,F}{G\,F} = \frac{\text{Sin } m}{\text{Sin } \left[\,90^\circ - (n + m)\,\right]}$$

or

$$B\,F = G\,F\ \ \text{Sin } m\ \frac{1}{\text{Cos } (n + m)}$$

$$\therefore\ AF + BF = GF\ \text{Sin } m \left(\frac{1}{\text{Cos } (n - m)} + \frac{1}{\text{Cos } (n + m)}\right)$$

$$A\,F + B\,F = K, \text{ and } G\,F = \frac{C\,D}{2}\ \frac{1}{\tan m} = \frac{C\,D\ \text{Cos } m}{2\ \text{Sin } m}$$

By substituting, and advancing to common denominator.

$$K = \frac{C\,D}{2}\ \frac{\text{Cos } m\ [\ \text{Cos } (n + m) + \text{Cos } (n - m)\ ]}{\text{Cos } (n + m)\ \text{Cos } (\ n - m)}$$

Reducing this :

$$C\,D = K\ \frac{\text{Cos}^2\ n\ \text{Cos}^2\ m\ -\ \text{Sin}^2\ n\ \text{Sin}^2\ m}{\text{Cos } n\ \text{Cos}^2\ m}$$

$$\text{as } d = M\,F = (f + c) + K^1\,C\,D$$

$$\therefore\ d = (f + c) + K^1\,K\ \frac{\text{Cos}^2\ n\ \text{Cos}^2\ m\ -\ \text{Sin}^2\ n\ \text{Sin}^2\ m}{\text{Cos } n\ \ \text{Cos}^2\ m}$$

The horizontal distance D = d Cos n.

$\therefore\ D = (f + c)\ \text{Cos } n + K^1\,K\ \text{Cos}^2\ n - K^2\,K\ \text{Sin}^2\ n\ \tan^2\ m.$

This third number of the equation may safely be neglected, as it is very small even for long distances, and large angles of elevation. At 1500 feet with angle n equalling 45 degrees, it is but 0.07':

Therefore, $K^1\,K\ \text{Sin}^2\ n\ \tan^2\ m = AB\,\frac{\text{Sin}^2\ n}{\text{Cos } n}\tan^2\ m = O$ approximately and the final formula for distances with a stadia rod kept vertical and with wires equidistant from the centre wire, is the following $D = (f + c)\ \text{Cos } n + K^1\,K\ \text{Cos}^2\ n$ (1)

and the vertical distance 2 = D tan n.

$$\therefore\ Q = (f + c)\ \text{Sin } n + K^1\,K\ \text{Cos } n\ \text{Sin } n$$

$$= (f + c)\ \text{Sin } n + K^1\,K\ \frac{\text{Sin}^2\ n}{2} \qquad (2)$$

When $K^1 = \frac{f}{a}$ focal distances, divided by distances apart of stadia hairs, and K = distance interrupted by stadia hairs in the rod.

By the above formula (1) and (2) both the horizontal and vertical distances can be immediately calculated when the reading from a vertical rod, and the angle of elevation of any sights are given. Tables, however, provide this data, saving the tedious calculations.

As regards the addition of the constant (f). Several suppositionary opinions have been advanced on the subject, each of the following having its advocates:—The common apex or point of convergency—principal focus—of the rays of light forming the two similar triangles, is:—The centre of the instrument; the stadia hairs; and the front face of the objective; none of which are really correct. The point towards which the rays of light converge when they emanate from a point at a distance from the lens vary according to that distance.

When the rays proceed from a point so distant that they may be considered parallel rays, they are refracted and converge to a point in the axis of the lens called the focus, or the principal focus, at a certain distance from the lens called the focal length of the lens, this distance depending upon the radii of curvature of the surfaces of the lens. In the figure the reason why the image is formed at distance F in front of the object glass is because the image of the cross-hairs is optically projected beyond the objective to the extent of the focal length of the latter. The rays converge at that point, and the measurement must be taken from it. Therefore, in order to obtain accurate results a constant must be added to the reading from that point. The constant

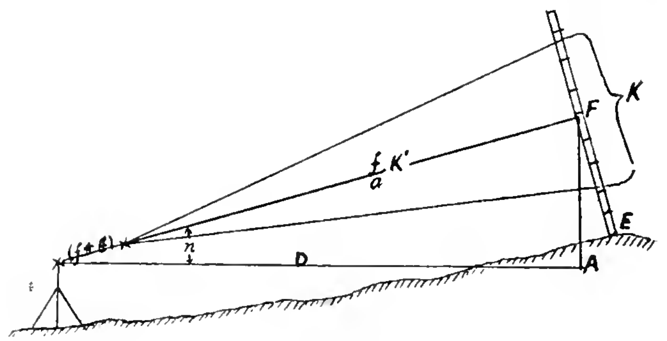

Fig. 3.

is equal to the focal length of the objective plus the distance from the object to the centre of the instrument; second, when the rod is always held vertical. But owing to this oblique view of the rod, it is evident that the space intercepted by the cross-hairs on the rod varies, not only with the distance, but also with the angle of inclination of the sight. In order, therefore, to obtain the true distance from station to station and its vertical and horizontal components, a connection must be made for this oblique view of the rod.

Page 17—The conclusions, therefore, are that as through the focal changes with distance (however slight) to the extent of .0052 ft. from 100 to 500 feet sights, it is plain that hairs adjusted at a distance of 100 feet will read correct distance at 500 feet, to the limit of (.0052—a). This would be somewhere like three inches. Not very much of an error, yet a needless one, and an error which may be partially if not wholly overcome by adopting a constant for each particular instrument, and not making the rule apply to an instrument by measuring. Each instrument has an individuality of its own, and must be adjusted by actual trial, and by making these adjustments, that is, adjusting the stadia hairs at a mean distance, not at 100 feet, nor yet 500 feet, but a mean distance between these, say at 300 feet, the difference of focal length is thus reduced one-half, or, for an 11-inch telescope of 30 magnifying power, the change in focal length at from 100 to 300 would be but .0027 ft., so that it will be possible to read all lengths of sights, from 100 to 500 feet to an almost perfect degree of exactness. This is refinement indeed, that, on rough ground, no chain measurement can approach, if on level ground in a series of distances. Once

the instrument is thus correctly fitted with fixed hairs, this refinement may be relied on, by always observing carefully and accurately.

General Uses of the Stadia.—For taking topography in country that will not permit a plane table; for coal drop line surveys, preliminary railway locations; for land surveys.

The Transit.—The instrument best suited for stadia surveying is an accurate transit with full vertical circle rigidly attached to the axis of the telescope and graduated to minutes from 0 deg. to 90 deg. in both directions. It should be provided with two double verniers attached to the horizontal vernier arm, the zeros of the two verniers being in a horizontal plane when the instrument is levelled up.

The horizontal limb should read also to minutes, there being no advantage in a reading of 30 sec. as the reduction tables, usually, do not reduce seconds. The graduations should number from 0 deg. to 360 deg. The graduations for the needle should also be numbered from 0 deg. to 360 deg., in opposite direction to the horizontal limb, and not be divided up in quadrants. This is important because in taking topography, for example, on either side of a railway line, the magnetic reading will approximately correspond with the horizontal vernier readings, and the needle only may be read which will greatly accelerate the work in hand. For very accurate work it is recommended to have a level attached to the vernier arm of the vertical circle. It will be found very convenient and probably more precise, than having to bring the telescope level to zero.

As between fixed or adjustable stadia hairs, it is immaterial so long as the rod reading is correct. Fixed hairs, however, are preferred for stadia work on the ground that errors due to variation of the wire interval are avoided, and a better focusing of the eye-piece.

An inverting telescope is to be preferred as it gives a wider field and a more sharply defined image. The eye-piece, known as the "Ramsden" eye-piece, and is termed a positive eye-piece, consisting of two plano-convex lenses, the convex-cut faces of which are turned toward each other. It is called an "inverting" eye-piece, but is not really so, as it is the object glass that inverts the image of the object viewed, and the eye-piece picks up the image in its inverted position. To get an equal clearness of vision with an "erecting" eye-piece as with a Ramsden, or "inverting" eye-piece, a correspondingly larger object glass must be used.

Stadia Rods.—For stadia work a self-reading rod is to be preferred, though for sights of 500 to 1,000 feet a target is necessary. It is quite impossible to read a rod accurately at 1,000 feet that has no target, even with a telescope magnifying 30 to 40 diameters. With a good target rod this distance can be read, in an ordinary atmosphere, quite accurately. But as distances of one to five hundred feet are most common a self-reading rod, divided into units, is best and handiest. As good a stadia rod as any is the "flexible," or tape rods tacked on to a light board twelve feet long. These tapes are made of prepared canvass, are strong and weather proof, and are convenient to carry. They are manufactured by Keufell and Esser, New York. The rod, or board, to which they are tacked should have a hinge in the middle for convenience in carrying. A certain distinct mark, easily seen at a distance, should be made or attached to the rod at the average height of the instrument, in order to get correct elevations. While this "height of instrument," marked on the rod in this way may not correspond to all heights of the instruments, it will, however, be an average height, and these average heights will correct themselves. In case the absolute height of the ground under the instrument, the height of the telescope at each station will have to be measured by the rod, and the difference between this measurement and the average height used in sighting to the rod either added or subtracted as the case may be. The difference will ordinarily be so small, that in a great deal of stadia work no reduction will be necessary.

In sighting to the rod for the angle of depression or elevation, the centre horizontal wire must always be used. A level should be used in the rod surveys, where the value of the land is not too high—say less than $50 an acre. In fact, any place where location and elevation are required at the same time. We would not regard it as accurate enough for city lot surveying, nor convenient where it is necessary to put in stakes at regular intervals of 50 or 100 feet.

We would hesitate to use stadia in a lost boundary suit, or in any place where it would be necessary to convince a jury that the work was accurate, although we feel that more accurate work can be done in rough country with stadia than with tape line providing care is used. Owing to the great chances of error we never feel satisfied with a line until it is checked by another line having a common beginning and ending. In taking topography over a large area the transit line will necessarily cross or join, so this checking takes little extra time.

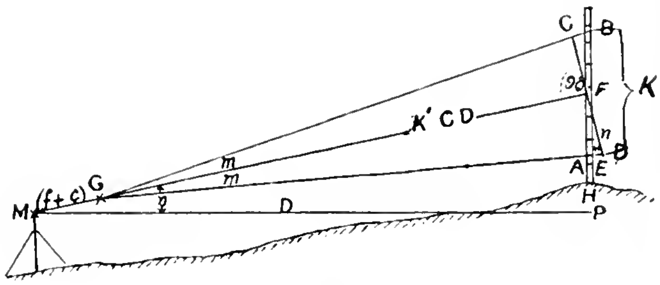

Fig. 4.

Fairchild and Gilchrist of Philadelphia, wrote the writer: "We find that errors balance; lines 10 miles long may check for elevation within a foot at the ends; and cross lines between be out as much as five feet. In the horizontal plane these errors generally do not vary so much. We consider a horizontal tie of lines between 2 and 20 miles long of 5 feet out, good; 10 feet, fair; 15 feet, questionable; and 20 feet, bad. This in a fair country. We should avoid steep sights rather than long sights, and try to get sights of average length on main transit lines. But if one can avoid a steep sight by taking a short fore-sight and long back-sight, or vice-versa, do so.

"Lengths of sights depend upon the atmosphere and the glass in the transit. Under fair conditions sights of 500 feet is good; 400 feet is a little better; 600 feet at pinch on main line; on side shots, 1,200 feet long is not uncommon.

"We add (f+c) to each rod reading, and then reduce for horizontal and vertical. The error in this is so slight that it can be disregarded. (f+c) is variable with each transit. It is important that transit be accurately adjusted, particularly plate bubbles. Only one sight is necessary. A level—a small round bubble level—is easily attached to the rod, and the rodman keeps the rod plumb by watching one bubble. Slide rods should be avoided, and a target, except for long sights, is unnecessary."

Preliminary Railway Surveys by the Stadia Method.—In making preliminary location surveys for roads or railroads, the stadia method enables the surveying party to go over the field much more rapidly, and in most cases is a cheaper method for that reason than using a level. Locating engineers, however, seem to have a decided preference for using a level for this work, chiefly because of the more ac-

curate data obtained. It would seem to be useless refinement to go over the ground with a level taking precise but tedious readings at every station, when these levels are usually only furnishing rough data to the engineer from which the final location can be determined. In a level country or on gently undulating ground, the final location can often be determined with no preliminary observations, and the levels for grade fixed from one survey, but usually all the work of the preliminary survey must be done over once, and often many times, before the line is finally located. The stadia method is a simple and rapid way of obtaining all the necessary data with sufficient accuracy for the purpose intended since both the topography and the bearing of the tangent can be found with one setting of the instrument.

It would seem that instead of having to make two or more preliminary surveys of a railway line, that one fairly careful reconnaisance be made over the ground in the first instance, taking the data of all elevations and depressions on either side to the distance of 500 to 1,000 feet, that the preliminary line that would follow would approximately be a location line, thus saving one or more preliminaries.

In adopting the stadia method we make a compromise between reconnaisance and preliminary, and this is perhaps what is needed. Our usual reconnaisances are too limited in data, trusting to what may be obtained with hand level, compass and aneroid, while our preliminaries are necessarily of too great refinement. The stadia, then, offers a solution—a compromise between reconnaisance and preliminary, in which in a good country no preliminary may be needed but the final location made from the stadia, while in rough country a preliminary will be needed, and one approaching in refinement, a regular location.

The stations in a stadia survey need not be placed exactly one chain apart, but can be taken 200 ft., 500 ft., or even 1,000 ft. apart if the ground is level. After setting up the instrument at a station, and getting a back-sight, the telescope can be circled round in azimuth and all the topography taken on either side of the line. The rodman can be signalled to place his rod where wanted and the angles of all hills and valleys within 1,000 feet be obtained. In long sights, three observations (in rough country) on either side of the line are needed, one between 0 deg. and 90 deg., one at or about 90 deg. from the tangent, and one between 90 deg. and the fore-sight. The elevation and distance of the next station should then be taken, and finally three more observations recorded for the topography on the right of the line, one between 180 deg. and 270 deg., one at 270 deg., and one between 270 deg. and 360 deg. The deflection angle, if any, must also be read on the horizontal vernier, while the side shots need only be read by the needle, this saving a lot of time. Progressing rapidly in this way the topography of the country through which the road is to pass can be plotted with reasonable accuracy. Ordinarily a couple of side shots will be sufficient. The rodman should carry small pegs or hubs to drive at the stadia stations, and on the points taken on the tangent or main line. The axman drives stakes beside the hubs in the same way as on railway hubs.

Reducing Stadia Readings.—When working in the field with a stadia, a stadia rule, as Colby's, or a cheaper one, Keufel and Esser's, or, perhaps, what is better, graphic diagrams, should be carried for making the corrections for differences of elevation, or $\frac{1}{2}$ Sin. 2θ (of observed angle), and, also, corrections for distance, Cos.^{2} θ. The constant of the instrument (f+c), may or may not be reduced to sine and cosine for small angles. The stadia rules are more convenient to handle than tables, and the graphic diagram, if made accurately, are even easier read. Any good draughtsman can easily prepare a diagram for Cos.^{2} θ, and Sin. 2 θ, from which corrections can be read direct for any observed angles and distances.

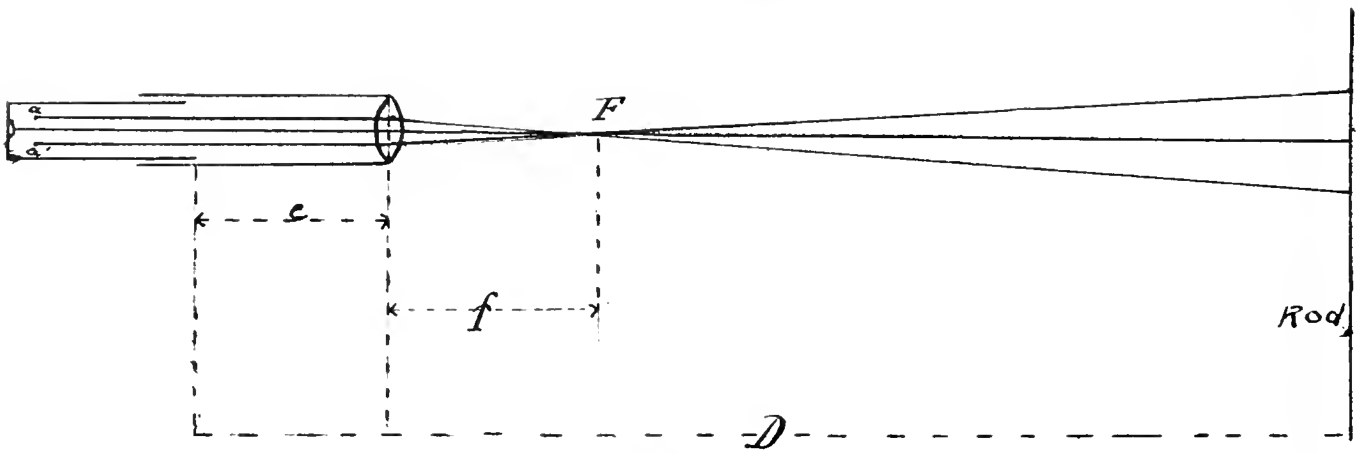

Fig. 5.

Keeping the Notes.—The most difficult part of a stadia survey is keeping notes in handy form. Books can be obtained which are ruled especially for stadia work.

Both the left hand and right hand pages are used and little room is left for the sketch on the ordinary size field books. Since the stadia reading must be corrected for differences of elevation it is perhaps better to enter the observed vertical angles and leisurely reduce with tables. The distance, however, should be reduced on the spot so as to mark on the stakes.

CONTRACTORS' WORKS IN CANADA.

Sir W. G. Armstrong, Whitworth, and Company, Messrs. Swan, Hunter and Wigham Richardson, and Messrs. Cammell, Laird and Company are negotiating for suitable sites for shipyards in Canada. Messrs. William Harkess and Sons, of Middlesborough, intend to open an establishment at Halifax, N.S., while Messrs. Denny, of Dumbarton, Messrs. John Brown and Company, the Fairfield Company, and Vickers, Limited, Barrow, are busy laying down plant at various places in the Dominion. The last-named firm also propose to build vessels at Sault Ste. Marie, an important point on the Great Lakes. So far, no decision has been arrived at by the Borden administration in regard to the request made by Canadian shipbuilders for further state assistance, but it is expected that the import duty on materials will be removed.—From Contractors' Chronicle.

EXHAUST STEAM AND ITS UTILIZATION.

By J. M. Gordon.

In the last issue of *The Canadian Engineer* we dealt with the utilization of exhaust steam in a paper by the above author which space did not permit us to publish in full. The latter portion of his paper, which deals more particularly with condensers and turbines, we take pleasure in publishing herewith.

The advent of the steam turbine has greatly influenced the design of the condenser, for in previous days any condenser giving a vacuum of 25 inches was considered all that was necessary; but nowadays the demand for high vacua has resulted in a condenser of far greater efficiency. In the use of condensers in mining plants a main difficulty is that the cooling almost invariably employed is derived from the mines. Such water is rarely below 56° F. This necessitates a large volume of water passing through the condenser; in fact, as much as can be economically allowed. Consequently, if the quantity of water is a factor of consideration, it will be essential to erect cooling towers or sprays, with settling reservoirs, as the temperature of the outlet water has such a bearing on the vacuum; in fact, some British engineers prefer expressing the vacuum from condensers by temperature, rather than by inches of mercury. Referring to Fig. 3, it will be found that each inch from 25 inches to 27 inches is equivalent to 4 per cent. consumption by the turbine; that between 27 inches and 28 inches, about 5 per cent., and from 28 inches to 29 inches, from 6 to 7 per cent.; or that approximately 3° F. difference in the temperature of the exhaust means about an increase or decrease of 1 per cent. in the consumption. This will demonstrate the importance of having the temperature of the outlet water as near as possible equal to the temperature due to the vacuum. The difference in a good modern condenser should not exceed 5° to 6° F. when condensing 12 pounds per square foot per hour. Another method of considering the efficiency of a condenser is by expressing it in B.T.U.'s transmitted per square foot of cooling surface per hour for 1° F. difference of temperature. In well-constructed surface condensers, such as Parsons, it can be as high as 1,200 B.T.U.

In the surface condenser the resistance to the heat absorbed from the steam by the water may be considered in three stages. In the first stage we have the transmission of the heat from the steam to the tubes of the condenser. This transmission is governed by the efficiency of the air-pump and by the quantity of air in the condenser. These factors can be greatly reduced by dry air-pumps or by the more recent method of the application of the Parson vacuum augmentor, which withdraws the air completely from the condenser. Air in a condenser is detrimental, since it not only vitiates the vacuum, but it also blankets the tubes and retards the transmission of heat. The second resistance is small, and hardly worthy of consideration. It is due to the metal of the tube. The third and last, but not least, resistance, is the final transmission of heat from the tube to the water. Should there be a crust of slime or carbonate on the tube the conductivity of heat drops considerably, and the efficiency drops. It is essential to keep the water in a violent state of excitement in order to prevent it having a clothing of temperatures. In recent years the application of Parson's augmentor has greatly improved the condenser. The augmentor is simply a set of steam pipes which sucks the vapor and air from the main condenser and delivers it through a small auxiliary condenser to the air pump. In practice this augmentor has been known to bring the conductivity from about 250 or 300 to between 800 and 1,000, or reduce the temperature from 26° F. to 5° F., a gain in temperature of approximately 21° F., or 7 per cent. in the total steam consumption of the turbine. This steam jet consumes 0.6 per cent. only of the amount of steam consumed by the main prime mover. In Scotland Korting Bros.' ejector condenser has been used in connection with mixed pressure turbines, and has proved eminently successful.

Discussing now the main prime mover, the turbine itself, we have a machine possessing many peculiarities and differing vastly from the old reciprocating engine. One of the chief differences is the mode of lubrication. In most types of mixed pressure turbines the bedplate is the receptacle for holding the oil, out of which it is pumped through the bearings, and thence through an oil-cooler, and again back into the bedplate. Thus the oil is used over and over again. These turbines are usually governed by centrifugal governors directly coupled to the shaft and in direct communication with the tachometer, working a trip gear, which in turn opens and closes the high-pressure nozzles according to the weight of load and supply of exhaust steam.

There are quite a number of mixed pressure turbines on the market; in fact, all compound steam turbines are adaptable for exhaust and mixed pressure use. The single stage, or De Laval turbine, is not adaptable, as the efficiency is regulated by the speed, the higher the speed the higher the efficiency of the machine, and it has been found that units

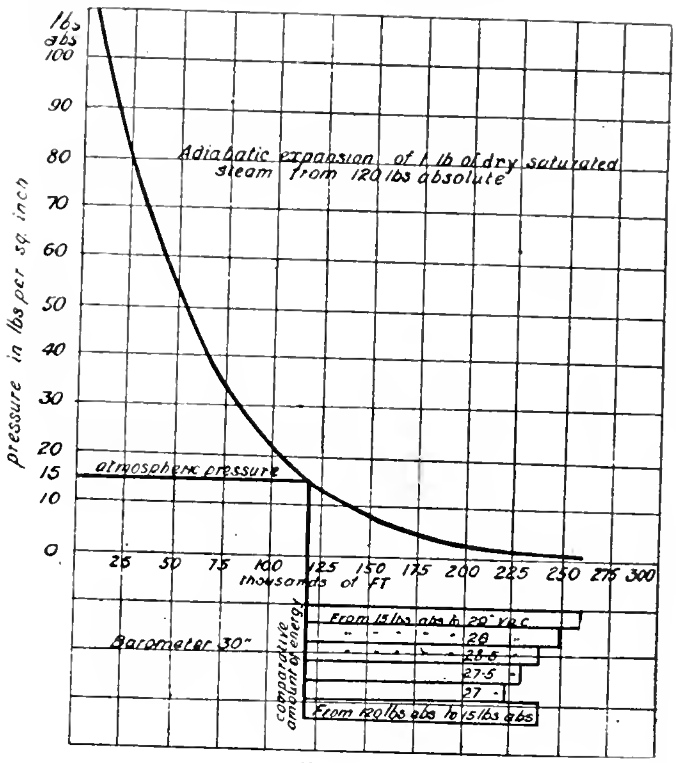

Fig. 3.

of from 200 to 300 kw. is about the highest economically obtainable. These sizes run with a periferal speed of about 1,200 per second, which is about the limiting velocity, for above this, centrifugal forces become too great. Another disadvantage is that the periferal speed being so high the turbo-generator cannot be directly connected to the machine, but has to be geared down.

The compound-stage turbine, as already mentioned, is divided into two sub-classes, namely, the reaction and a combination of impulse and reaction. In the first sub-class we have Parsons, while in the second we have the Rateau, Zoelly, Curtis, Bergman, Riedler, Stumpf, Sulzer and Echer-Wyss. The first sub-class being the first type to be constructed had to contend with the fierce cutting action of superheated high-pressure steam on the blades; and to reduce this action as far as possible, the expansion is divided into a number of stages, thus reducing the velocity of the steam, while also reducing the high periferal speed and revolutions. Mean-

while metals or alloys have been discovered to withstand this high eroding properties of superheated steam jets at great velocities; and there is now in the market a combination of the impulse and reaction turbine with very few stages.

Without discussing the details of the respective types, a short resumé of the better known turbines will not be out of place.

The Parson turbine consists of a long cylindrical drum, increasing in diameter by stages from the high to the low-pressure end. This drum is mounted on a shaft revolving in two pedestal bearings, and the whole is enclosed in a cast-iron casing. On the perifery of the rotor are placed alternate rows of fixed and rotating blades or vanes. These blades are fixed in dovetail grooves with distance pieces placed between them and cranked into position. The increase in size of the blade in the low-pressure end requires it to be stiffened by shrouding. The fixed blades project inwardly, while the revolving blades project outwardly. The steam enters in the bottom of the high-pressure end of the cylinder, leaving the top clear of steam pipes, thus much facilitates dismantling. The steam first passes through a ring of fixed or guide blades, and in so doing the pressure falls and proportionately the velocity of the steam rises, and is then projected in a rotational direction against the neighboring ring of rotating blades, whereby work is done upon the blades, and hence the acceleration of the rotation of the turbine. This is carried on through the different stages until the steam is fully expanded, and it then exhausts into a condenser.

In this type of turbine the steam, in addition to giving a rotational force, exerts an end-wise pressure along the

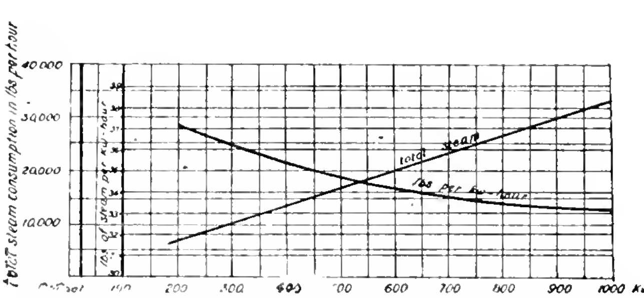

Fig. 4—Consumption of Steam by an Exhaust Steam Turbine. Vacuum 28″ (Bar 30″).

shaft, on the surface of the blades. This is now counteracted by dummy pistons for the different stages or sections, each presenting an area equivalent to the mean blade area of the section it is intended to balance. Thus the turbine shaft runs in complete balance endways, and after the critical speed has been reached the shaft can be moved backwards and forwards with a lever with comparative ease. A claw type of flexible coupling is usually used for connecting the turbine with the generator to allow for any slight difference in alignment. A thrust block is placed at the steam end of the turbine shaft to give the proper clearances and adjustments between the fixed and moving blades. In the small sizes of Parsons turbine the shaft is usually made from a solid steel forging, but in the larger sizes hollow steel drums, which are machined both outside and inside, are fitted together and carefully shrunk and pinned. The lubrication of the bearings, thrust-block and governor gear is automatically performed by a rotary pump driven from the worm-wheel of the centrifugal governor; and, as it is placed low down, it is continually flooded; hence it is almost impossible that it would fail to perform its function. The main bearings are made of gun-metal. The bushing is held in position by a loose-fitting dowel, and is surrounded by three concentric tubes, the annular spaces being filled with oil in order to damp vibrations; this causes the bearing to be practically self centring.

The Sulzer turbine consists of a partially injected impulse turbine for the high-pressure stage, and of a fully injected reation turbine for the low-pressure stage. The blades of the impulse wheels are made of a high-grade nickel steel, while the reaction blades are made of a special bronze. Unlike other turbines, this type does not make an oil well of its bed-plate, but has a special vessel usually kept in the basement of a power-house. This is a precautionary measure against the possibility of grains of sand finding their way into the oil. In order to obtain oil when the turbine is at rest a small steam auxiliary oil pump is provided, which is usually attached to the bed-plate. A device is provided in the turbine to make it impossible to start the turbine before the complete oil system (governor, bearings and balancing disc) is under pressure. In this type of turbine, in sizes up to 1,500 horse-power, an ordinary collar bearing is used to take up the axial thrust, but in the larger sizes a small oil-pressure balancing disc is used which is attached outside of the high-pressure bearing, and is keyed on the shaft.

The Curtis turbine, like the Parsons, is made by more than one firm in different countries. In Germany, a very excellent type of the Curtis mixed-pressure turbine is made by the Allgemaine Elektricitats-Gesellschaft, while in Great Britain the British Thomson-Houston make a unique high-pressure Curtis turbine with the generator directly above the power producer, the low and mixed-pressure type being of the horizontal construction.

In this type of mixed-pressure turbine the expansion is performed in two stages. The first expansion takes place in a row of nozzles, which brings the steam down to approximately atmospheric pressure, and its energy is then taken up by the turbine wheel, usually comprising two rows of buckets with two velocity stages. From this point the steam is exhausted into a chamber and there passes through a second series of nozzles into the low-pressure end. This second series of nozzles is divided into two sets, one set conducting the exhaust steam from the high-pressure stages, and the other set conducting the exhaust steam from the accumulator. These sets are so constructed that the exhaust steam in the accumulator gets the preference, and it is only when the load becomes too great, or the exhaust steam fails, that the turbine slows down, or rather the tendency to do so causes the governor to open the high-pressure nozzles to the amount of the deficiency; and, as soon as the exhaust steam from the generator can take the whole load, the governor once more closes the high-pressure nozzles. The governor is usually set for a speed regulation of 2 per cent. between full and no load, with a maximum monetary variation of 4 per cent. for the purpose of synchronizing and making the turbine bear a proportional share of a peak or sudden extra load. An emergency governor is also fitted to this turbine, so that at any time, should the main working governor fail, and the turbine increase to 15 per cent. above the normal speed, a trip-gear would act and cause the throttling of the valve in the main steam pipe until such a time as the normal speed was again reached.

These low-pressure and mixed-pressure steam turbines are usually directly coupled to a three-phase alternating generator. Three-phase alternating current is almost universally adopted because of the economies in the transmission lines, while also three-phase induction motors are admirably adaptable for pumping work and haulage. The great disadvantage the system once had was the sudden drop of voltage on the main alternator, when a fluctuating or a peaky load was encountered, such as occasioned by one or two haulage motors commencing operation on or about the same time. This difficulty has been overcome by automatically varying the resistances in the exciter field through solenoids actuating moving contacts.

Low-pressure turbines have also been applied to rotary air compressors, and are found economical when the demand

on a reciprocating air compressor exceeds the supply. By so utilizing the exhaust steam of the reciprocating set the rotary set will supply air at 30 pounds absolute to the main compressor, and thus almost double the output of the main set with no more steam than was used previously.

The capital or initial costs of a high-pressure set and a mixed-pressure set are compared in the following table. The operating expenses for a twelvemonth at an average deep colliery where exhaust steam is plentiful are also computed. As the plant under construction is of two units, each of 1,000 horse-power, the reciprocating engine is not considered:—

Capital Costs.

Plant 2, 750 Kw. Sets.	H.P.	M.P.
Power-house and crane	$ 8,250	$ 8,250
(2) 750 kw. turbo-generators, complete	50,400	60,000
Complete installation of two condensing sets	15,000	23,000
One cooling plant	4,000	6,500
Battery of boilers with essentials.....	30,000	....
One regenerator	....	8,000
	$107,650	$105,750

Advantage for Mixed Pressure Turbine, .65 Cents per Useful Unit.

In conclusion, an interesting instance in support of the foregoing argument may be here cited. In the power station of the Edinburgh Corporation, Scotland, were eight Willin & Beliss engines, each of 1,200 horse-power, designed to operate with a 25-inch vacuum; but because of a lack of water these engines were not operated non-condensing. Mr. P. S. Mitchell, of Glasgow, Scotland, collected the exhaust steam from four of the engines and installed two Rateau low-pressure turbines with a Brown Boveri, D.C. combination at 490 to 500 volts. Each of these turbines is capable of developing 1,250 kw. when supplied with 45,600 pounds of exhaust steam per hour. Two of the reciprocating engines have a total output of 1,550 kw. Consequently the output has been increased no less than 80 per cent. by the utilization of what was formerly waste steam. The condensers installed were the contra-flow condensers made by Richardson & Westgarth, and it is interesting to note that this Scottish engineer had the boldness to use the sewage water of the city of Edinburgh for circulating purposes.

OPERATION OF TRAILERS IN CONNECTION WITH PEAK LOAD CITY SERVICE.

A description of the operation of trail cars in Cleveland is given by Mr. G. L. Radcliffe, general manager of the Cleveland Railway, in a recent number of the Electric Railway Journal. The article deals principally with the changes made in equipment since the trail car was last in general use.

With adequate motors and improved tracks, its operation is no longer hazardous; its application to traffic problems is definite and easy. No more a makeshift, but specially designed to meet certain conditions, it is in every way a worthy running mate for the modern motor car. The first modern trailer operated on the system of the Cleveland Railway Company was placed in service September 16th, 1912. One hundred are now on our lines, and a second hundred will shortly be added. The operating features of this equipment necessitates a brief description of the car itself.

The extreme length is 49 ft., and there is no platform or vestibule at either end. A continuous longitudinal seat completely encircling the interior gives a maximum seating capacity of seventy-two and leaves a very large area for standing passengers.

The cars are mounted on Brill No. 67-F trucks, with 22-in. wheels, bringing the floor of the trailer close to the ground and making entrance to the car easy. It is but one step from the ground into the car—15 in.—and a second step of the same height to the car floor proper.

There are two doors in the centre of the car, one for entrance, the other for exit. The fare-box is placed opposite the post which separates the doors. The conductor's position at the box is facing the rear, so that an aisle is open between the fare-box stand and the devil-strip side of the car. The stand supporting the fare-box has a small shelf for change, on which is mounted a set of push buttons to govern the doors. Each door is opened and closed by compressed air electrically controlled by the conductor through the push buttons. The opening and closing of the doors flashes signals to the motorman by an electric contact, which should make trailer operation much safer than when he is entirely dependent on the signal bell.

The trailer is pulled by a 38-ft. motor car, equipped with four 40-h.p. motors of the Westinghouse 307-F type. The train is equipped with Westinghouse semi-automatic brakes and is coupled with the Tomlinson automatic air coupler. The couplers, while not yet entirely perfect, are a great improvement over the couplers in general use on the old-type train. Cars equipped with the modern automatic air coupler can be coupled much more quickly and with much less danger to the employee than formerly, while the application of air brakes to both cars reduces very largely the danger of accidents through the heavier equipment. These two features, we believe, with the electric signal device, give the requisite safety both to employees and the public.

When these trailers were first put in operation it was decided that we should use them only during the rush hour, morning and evening, and that trains would be left coupled so that it would not be necessary to switch, couple and un-

couple them several times each day. This method of operation is still pursued, and at present the motor cars are laid up during the greater part of the twenty-four hours. Upon the arrival of the next hundred trailers, however, it will be necessary for us to uncouple the trains in order to have the use of the motors during the day.

The first, and probably the greatest, advantage in operating trailers is in the cost of equipment. It will readily be seen that the elimination of motors and other electrical equipment from the car greatly reduces the cost of the equipment necessary to move rush-hour traffic, and the investment in idle equipment is smaller in proportion.

A second advantage is the carrying capacity of the trailer. In our case it is about twice that of the motor car. Seating seventy-two, while the motor seats but thirty-eight, the arrangement of seats noted earlier in this paper gives the trailer a standing area even larger in proportion than the similar area in the motor car. Thus, while the seating capacity of one of our trains is 110 passengers, we have carried over 350 passengers on a rush-hour trip, and it is not unusual to find 200 passengers on one trailer.

Another advantage is the reduction in operating costs made possible. The heavy extra loads just mentioned require the addition of only one man to a crew to handle, the trailer being in charge of one conductor and the train manned by the regular crew.

All the cars on the system of the Cleveland Railway are equipped with fare-boxes, and most of them are operated on the pay-enter plan. When the trailers were adopted it was intended to operate them also as pay-enter cars, but on account of the single-entrance and no-platform features it was found that loading took too much time and the method was changed so as to utilize the rear half of the trail car as a loading platform. Passengers boarding the trailer pay their fare as they go past the fare-box to the front end of the car, or if they go to the rear of the car, they do not pay their fare until leaving the car. In this manner about half of each load pays fare on the pay-enter plan and the other half on the pay-leave plan. This method has proved very satisfactory, and little confusion resulted from the change in method, even when first put into effect.

We did experience a great deal of trouble for a time on account of the slowness of trains in getting over the line when mixed with single cars. It developed, however, that the slowness of operation was due rather to the inexperience of the platform men than to the number of passengers carried on the trains, and, after six months' operation, we find that the amount of time necessary to operate a train over a given line is but little more than the amount required for a single car on the same line. The difference is so small in comparison to the amount of money saved in equipment and in the number of trainmen worked as to be negligible. In making up our schedules we arrange all runs so that both motormen and conductors can act as conductors on trailers during the rush hours. This, of course, requires fewer men to operate our schedules with any given number of cars than would be required if each car must be operated by two men. We find, also, that our runs can be arranged to better advantage by this method.

The train signal system between conductors and motormen is giving us some little trouble, trains being delayed for signals and slow in getting away from stops. Under our rules, even though a motorman receives his bell signal from the conductor, he should not start his car until he receives the signal light in the vestibule, indicating that all doors on the train are closed. Our present equipment being overtaxed in the rush hours, it often happens that passengers, attempting to crowd their way into cars already filled, stand in the doorways and prevent doors from closing. The conductor, busy at the fare-box, is unable to get to the door to get the passengers off the step. So it has been necessary to station inspectors at some points to clear the steps so that doors may be closed and the train properly started. We believe that this trouble would entirely disappear if we were operating sufficient cars to take care of the traffic and to prevent passengers from gathering in such large numbers.

The distribution of equipment, ever important, is especially vital to the success of trailer operation. We have not yet been able to work this out to the best advantage because of the mixing of single cars with trains, already referred to, but are hopeful that with the second hundred trailers a better adjustment can be made.

Little trouble has been given us at switches on account of operating trailers. Some motormen in their endeavor to keep their trains on time accelerate their motors too quickly when passing over switches, not waiting until the rear truck of the trailer has cleared the switch before they attain the maximum speed of their motors.

The operation of trailers in connection with peak-load city service depends entirely upon the peculiar local condition of the particular city service to which the trailer is to be adapted, and I have thought best to give you merely our experience without attempting the broad application of that experience. But I would say this much—as a personal opinion—I feel that the trail car is suitable only for peak loads, and they must be real peaks. A four-minute headway is the minimum which I consider warrants trailer operation.

AMERICAN SOCIETY OF CIVIL ENGINEERS' CONVENTION AT OTTAWA.

Preliminary arrangements have been made for the forty-fifth annual convention of the American Society of Civil Engineers at Ottawa, Ont., June 17th to 20th, 1913. Charles H. Rust, city engineer of Victoria, B.C., is chairman of the Committee of Arrangements of the Board of Direction. Charles Warren Hunt, secretary of the American Society of Civil Engineers, and Henry W. Hodge are the other members of this committee.

The following are members of the local committee:—

Charles H. Keefer, chairman; S. J. Chapleau, C. R. F. Coutlee, A. A. Dufresne, G. H. Duggan, Sir Sandford Fleming, H. Holgate, J. A. Jamieson, Phelps Johnson, T. C. Keefer, C. H. Mitchell, W. F. Tye, G. W. Volckman.

Most of the members who expect to attend the convention will be in Ottawa by Tuesday morning, June 17th, and in the afternoon will be tendered a reception by the Ottawa city officials. In the evening there will be an informal reception, with dancing, so that members of the party can become acquainted. At ten o'clock Wednesday morning, June 18th, the president will deliver the annual address, at the termination of which the business meeting will convene.

The local committee is arranging for various meetings and excursions. It is expected that there will be two evening lantern slide lectures, descriptive of engineering work in Canada; several excursions to points of local interest; a garden party; golfing at the Royal Ottawa Golf Club links, etc. A reception will be tendered by the Canadian Society of Civil Engineers to the visiting members of the American Society.

The entire programme is subject to change, excepting the time for the president's address and the business meeting. The headquarters of the convention will be the Chateau Laurier.

The expenditure on the harbor and railways in the South African Union for the ensuing year is estimated at £13,774,550, which is an increase of nearly £300,000 on the previous year. This is exclusive of capital expenditure in respect of the construction of new railways.

COAST TO COAST.

Ottawa, Ont.—Hon. J. D. Hazen has given notice of a government bill providing for a federal loan of $3,500,000 to the Quebec Harbor Commission to enable the commission to construct such terminal facilities as are necessary to properly equip the port of Quebec. The money is to be advanced from time to time as needed. The bill contains provisions similar to those in the act passed some years ago in regard to the Montreal Harbor Commission.

Vancouver, B.C.—At Nanaimo on March 4, at the opening session of the western branch of the Canadian Mining Institute the secretary drew attention to the better position British Columbia had reached in regard to loss of life in its coal mines. For the ten-year period, 1903-1912, the death rate was 5.08 killed per thousand employed, while for the five-year period, 1908-12, it will be found to have been 4.34 per thousand employed. Credit should be given, in justice to the provincial department of mines, the officials of which, during recent years particularly, have done their utmost to ensure the safety of coal mine employees.

Montreal, Que.—The announcement was made recently in London, England, of what is thought may prove an epoch-making invention in the steel trade. It is alleged that a process has been discovered for converting iron ore of any grade (even sands, of which hundreds of millions of tons exist ready for working) into steel of excellent quality without the aid of a blast furnace, the steel being produced direct, in a single operation. Tests have already been made of the steels so produced at an experimental plant and the results obtained are remarkable. No blast furnace is required, and no coke, which means an initial saving of capital expenditure as well as economy in production, while ores can be used which, at the present time, have no market value whatever. The ore is reduced by heat obtained from a gas, which is produced from slag. It is claimed that steel can be made at one-third of its present cost.

St. John, N.B.—Negotiations are now going on for the construction of the final 225 miles of the Canada and Gulf Terminal Railway connecting the present terminus at Matane with the Basin of Gaspe. The projected line runs through the very centre of the Gaspe Peninsula, about which very little was known up to a few years ago, yet the announcement is now made that complete surveys and locations have been made along the entire route, and that construction will probably be begun during the coming summer and continued for two or three years, as it will probably take that length of time to bring the rails down to the big government wharf now being constructed at Gaspe Basin, where there is at least forty feet of water at low tide. The federal government have subsidized this enterprise at the rate of $3,200 per mile, and this sum will be doubled if the cost of the railway reaches a certain sum. On the other hand, the Quebec government have granted a subsidy of three thousand acres per mile for the entire 225 miles.

Montreal, Que.—Montreal electrical engineers have become interested in Mr. Denys L. Selby Bigge, the English electrical expert, who is promoting direct current transmission of electric energy for long distances. Some of the advantages of his system are as follows: Long distance transmission of electricity in bulk with ground return to distances of 400 to 500 miles. The electrification of railroads, owing to the low cost of transmission, and feeders for the line, which in conjunction with a new form of high tension direct current traction motors and trolley line, would greatly reduce the construction and operative costs. The ease with which pulp mill or other industries in which direct current motors of high power are used, could be driven from the initial generating source, directly in series with the line, without any transformation either up or down—thus effecting great simplicity and efficiency in operation. The direct current system is not altogether new to Europe. The system has been in operation for four and a half years from Moutiers, in Switzerland, to Lyons. It was found possible to extend the system considerably, and has been linked up with water powers at Bredoire and Roselle.

Ottawa, Ont.—During the past few weeks the Canadian Northern Railway Company has been pressing the government to come to its assistance in a generous manner and assist the company to meet pressing financial obligations in connection with the completion of its transcontinental line. Sir William Mackenzie is now in Europe in connection with a general financial re-organization scheme, on behalf of the Mackenzie and Mann railway and allied enterprises. It is understood that the world-wide financial stringency has had a serious effect on the efforts to float new loans to keep all their gigantic and inter-related interests from suffering through the lack of ready money. The appeal for federal assistance has been pending for some time, but government action has so far been delayed by the exigencies of the naval issue. It is understood that the measure of assistance sought involves some twenty-five million dollars, partly by way of direct subsidies for the company's lines not hitherto subsidized from the federal treasury, and partly by way of a loan on the security of the company's railway lines. The details of the legislation have not yet been finally worked out, but it is understood that a general basis of agreement has been reached between the government and Sir William Mackenzie and Sir Donald Mann. The railway company claims that, in view of the magnitude of its undertaking, it is entitled to federal assistance proportionate to that given to the C.P.R. and the Grand Trunk Pacific.

PERSONAL.

MILLIS M. FERGUSON, graduate of Queen's University in '04, has resigned his position of city engineer of Guelph, Ont.

MR. HOLLAND, assistant city engineer of Guelph, Ont., has been appointed temporary city engineer in place of Millis Ferguson, resigned.

GEO. T. CLARK, B.A., graduate of Toronto University in Civil Engineering, of class '06, has resigned his position as city engineer of Saskatoon.

MR. R. H. THOMSON, late city engineer of Seattle, Wash., now engineer in charge of Strathcona Park for the province of British Columbia, and Mr. C. H. Rust, city engineer of Victoria, B.C., have been requested by the provincial government to report upon the proposed sewage scheme for greater Vancouver, which has recently been submitted to the various municipalities interested by Mr. R. S. Lea, of Montreal. The government have agreed to guarantee the interest upon bonds to the extent of five million dollars, this being the amount that Mr. Lea recommends should be expended at once. The remaining five million dollars to be spread over a period of some years.

MR. B. RAYMOND PHILBRICK has been appointed head of the buildings branch of the Department of Public Works, Saskatchewan, taking the place of Mr. W. P. Coltman, who has resigned by letter from England. Mr. Philbrick has been in the employment of this government for the past three years, and is a surveyor who commenced his

career in Cape Town. He took part in the Jamieson raid, and after a term in the Matabeleland Mounted Police, resumed the practice of his profession in England. With his father Mr. Philbrick became a large contractor for several public works, prior to coming to Alberta. He has until recently been supervising the work of constructing the hospital for the insane at Battleford.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

At a meeting of the Vancouver Branch of the Canadian Society of Civil Engineers held recently, Mr. A. D. Creer, chief assistant to Mr. Horace Lea, the consulting engineer of the Burrard Peninsula Sewage Disposal Commission, outlined the work which it is hoped to undertake in order to efficiently dispose of the sewage of the Burrard Peninsula area. There are five drainage areas, Mr. Creer stated. namely, the Fraser River, False Creek, English Bay, Burrard Inlet and Burnaby Lake. The total area to be taken care of is 52,000 acres. Mr. Creer read passages from the report of the consulting engineer showing the way in which sewage effects the waters into which it is emptied and the plans which the commission have adopted as being able to cope with the problem.

COMING MEETINGS.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.—Meeting of the Toronto Section will be held at the Engineers' Club, 96 King St. West, at 8 p.m., Friday, March 28th. Secretary, H. I. Case, 709 Continental Life Bldg., Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, T. S. Young, 220 King Street W., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Mucklestone; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson. Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubec, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

An Engineering Weekly

CALCULATIONS FOR THE STABILITY AND DISPLACEMENT OF GRAVING DOCKS

By LEONARD GODDAY, C. E. and M. E.
Late of the British Admiralty.

In dock construction there are several important points to be carefully taken into account and calculated in determining the section of the walls and bottom, viz., the pressure of the ground according to its composition or water, as the case may be, against the walls, and also the upward pressure of water against the bottom.

There is also the displacement of the dock itself, which is most essential to take into account when the sub-soil is saturated. This is nearly always the case when a dock is constructed at the entrance of a river, because the land is generally swampy and consequently filled up to the required level, and it follows that made-up ground has to be dealt with.

These methods of working were for a graving dock, carried out some years back in the old country, and the section had to be rather heavy on account of the soft nature of the ground to some depth.

The preliminary step is to decide upon the interior dimensions so that it will be large enough for the largest ship likely to be built in the future, such as length, breadth and depth.

Next, draw a section of the walls which are estimated with experience, to about the right section that will serve as a basis to start calculations, which will determine whether they can be lighter or heavier, as the case may be, and which is governed to a great extent by the displacement of the dock.

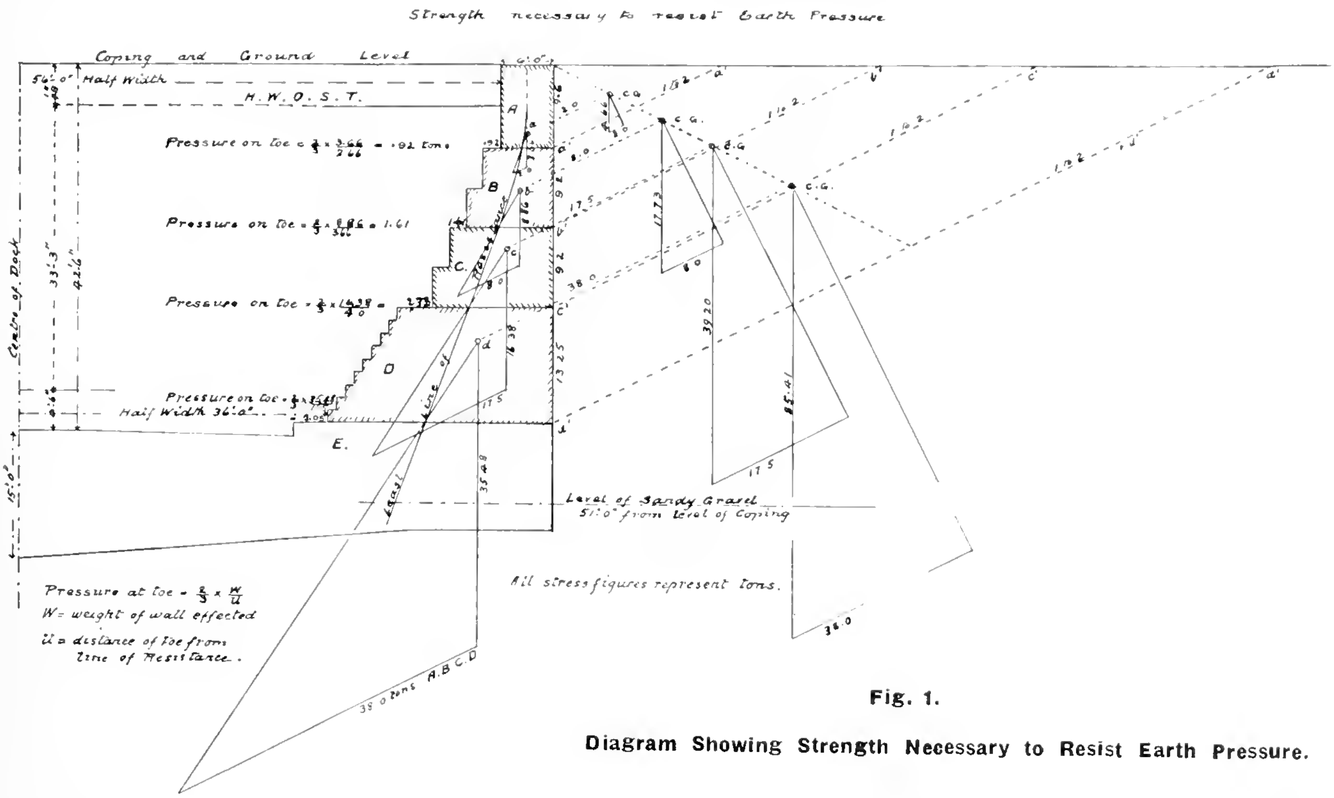

Fig. 1.

Diagram Showing Strength Necessary to Resist Earth Pressure.

Starting with the diagram (Fig. 1) for earth pressure, the wall section was divided and lettered A, B, C, D, etc., as shown. The angle of rest was taken as 2 to 1 for earth. The sections calculated are always taken as 1 ft. wide for convenience, as any length required will always be a multiple of this. The weights given are always in tons.

To begin, find the weights of A, A and B, A, B and C, and A, B, C and D, and which are 3.66; 8.86; 16.38 and

35.48 respectively. Similarly find the weights of earth prisms which are 4.66, 17.53, 39.20, and 85.41, and C.Gs of the prisms of earthwork which press against the sections of walls respectively, as mentioned, and whose angles of rest are represented by the lines a'a', b'b', c'c', and d'd'. From the C.Gs of these four prisms draw the stress diagrams, as shown, having their weights as data, and from these C.Gs draw lines parallel to the angle of rest until they cut the vertical lines drawn through the C.Gs of the wall sections. From these points of intersection construct the stress diagrams, as shown with the weights of the wall sections and earth thrusts found by the first stress diagrams as data.

Through the points of intersection of the third sides of these last stress diagrams, and the base of each wall section draw in the curve which is the least line of resistance.

representing their pressures, viz., 1.3, 4.9, 11.2 and 24.0 until they cut the vertical lines drawn through the C.Gs of the wall sections, as in the last case. From these points of intersection construct the stress diagrams, as shown, with the weights of the wall and the hydrostatic pressures as data. Through the points of intersection of the third sides of these last stress diagrams, and the base of each wall section draw in the curve which is the least line of resistance. It will be seen that the pressure per square foot on the base of each wall section, as in the case for earth pressure, leaves a good margin of safety.

The next step is to make a trial calculation for the bottom, which was drawn to a thickness of 12 feet at centre in diagram in Fig. 4, and the radius of the extrados as 14 feet, the depth at the skewbacks A and B became 8 feet.

Strength necessary to resist Water Pressure.

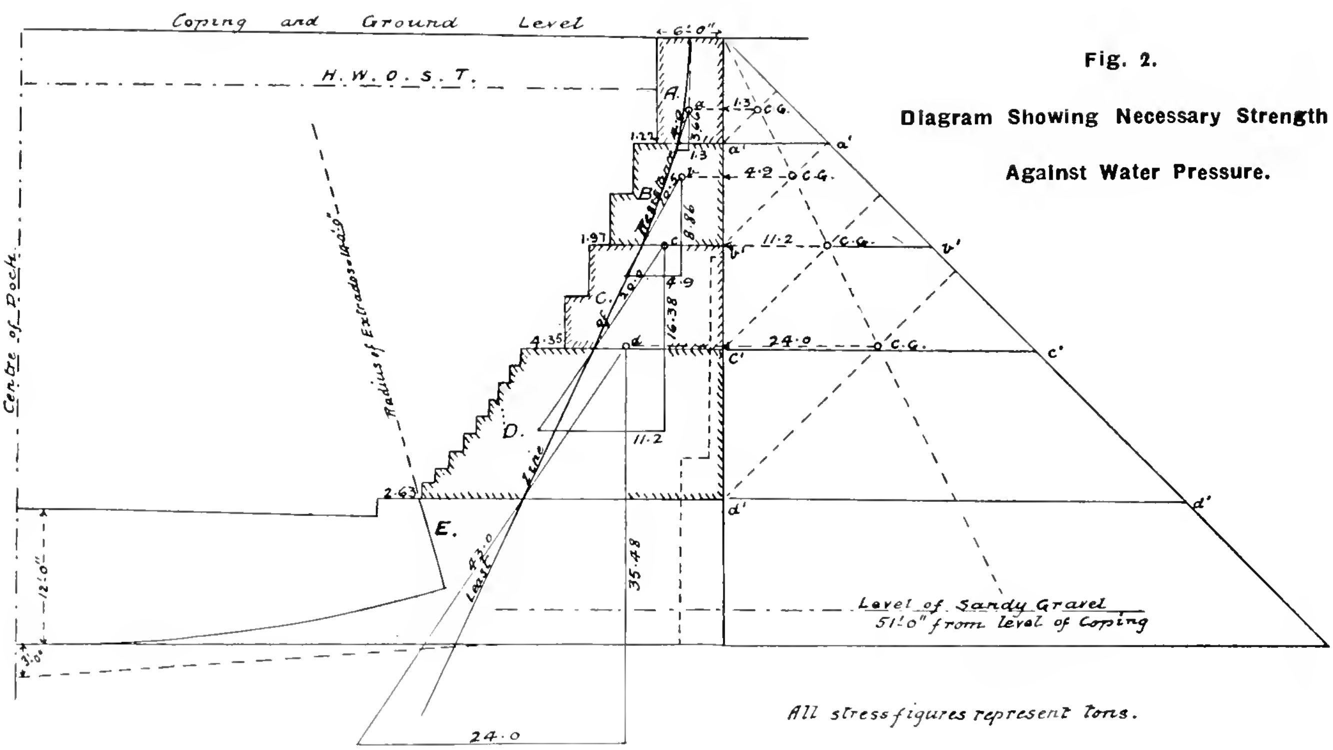

Fig. 2.

Diagram Showing Necessary Strength Against Water Pressure.

All stress figures represent Tons.

It is easily seen that the thrusts which are expressed by the third sides of the last stress diagrams divided by ⅔ the base of each wall section gives so small a pressure per square foot compared with the pressure allowed, viz., 12.0 tons, that there is every security in this case.

Lastly, find the toe pressure for one square foot at the toe of base of each section which is reckoned as ⅔ weight of the section of A, A and B, etc., divided by the distance of the least line of resistance from the toe, which calculation is shown on the diagram in each case. These pressures are seen to be well within that allowed, viz., 12 tons per square foot, and having a good margin of safety, will allow these walls to be reduced, when the calculation for displacement is being carried out.

Next draw the hydrostatic pressure for water, as in Fig. 2, as follows:—

Draw the diagram representing these pressures on the walls A, A and B, A, B and C, and A, B, C and D, as shown, their bases being a'a', b'b', c'c' and d'd' respectively, and which are subtended at coping level by an angle of 45° 00' common to all; and from their C.Gs draw the horizontal lines

Draw the horizontal line between the skewback representing the calculating span, viz., 73.5 ft. at 2.66 ft. from the top corners being ⅓ of 8 ft., and let the calculating depth at centre be from this line to a point ⅓ of 12 ft., i.e., 4 ft. from the base, and which makes it 6 ft. 6 in. The point of 4 ft. from the base is the extreme point of the middle third, and which is taken as the point for the horizontal thrust. The actual upward pressure equals the hydrostatic pressure, less the weight of the bottom, and which becomes 6¼ on each voussoir, and which acts through their C.Gs which brings the total upward distributed load of 50.0.

$$\text{Now, H} = \frac{\text{W.L.}}{\text{8.D}} = \frac{50 \times 73.5}{8 \times 6.5} = 70.7 \text{ horizontal thrust}$$

at the centre. Produce this thrust by a line α until it meets the vertical line through the C.G. of voussoir F, and from this point of intersection draw a line β parallel to the line β in the stress diagram for the dock bottom until it meets the vertical line through the C.G. of voussoir G. and continue, as shown, to the skewback, which gives a thrust of 75 feet.

The thrust at centre becomes $\frac{70.7}{12} = 5.9$ per sq. ft.

The thrust at skewback becomes $\frac{75}{8} = 9.4$ per sq. ft.

Taking the calculating d as ⅔ of thickness at centre, then thrust at centre becomes $\frac{70.7}{8} = 8.84$ per sq. ft., and

This is too small as a margin of safety.

The bottom at centre was next made 3 feet deeper, or 15 feet altogether, and then a line drawn 1 in 12, as shown, on either side until they cut the horizontal line first drawn. Also, the sides were benched in 1 ft. 3 in. and 2 ft. 6 in., as on diagram, and fresh calculations made, as per Fig. 3.

The section in Fig. 3 is practically the same as per alteration given above, and as shown in Fig. 4. The method of carrying these calculations out are similar to those in Fig. 4, with far better results for the pressures per square

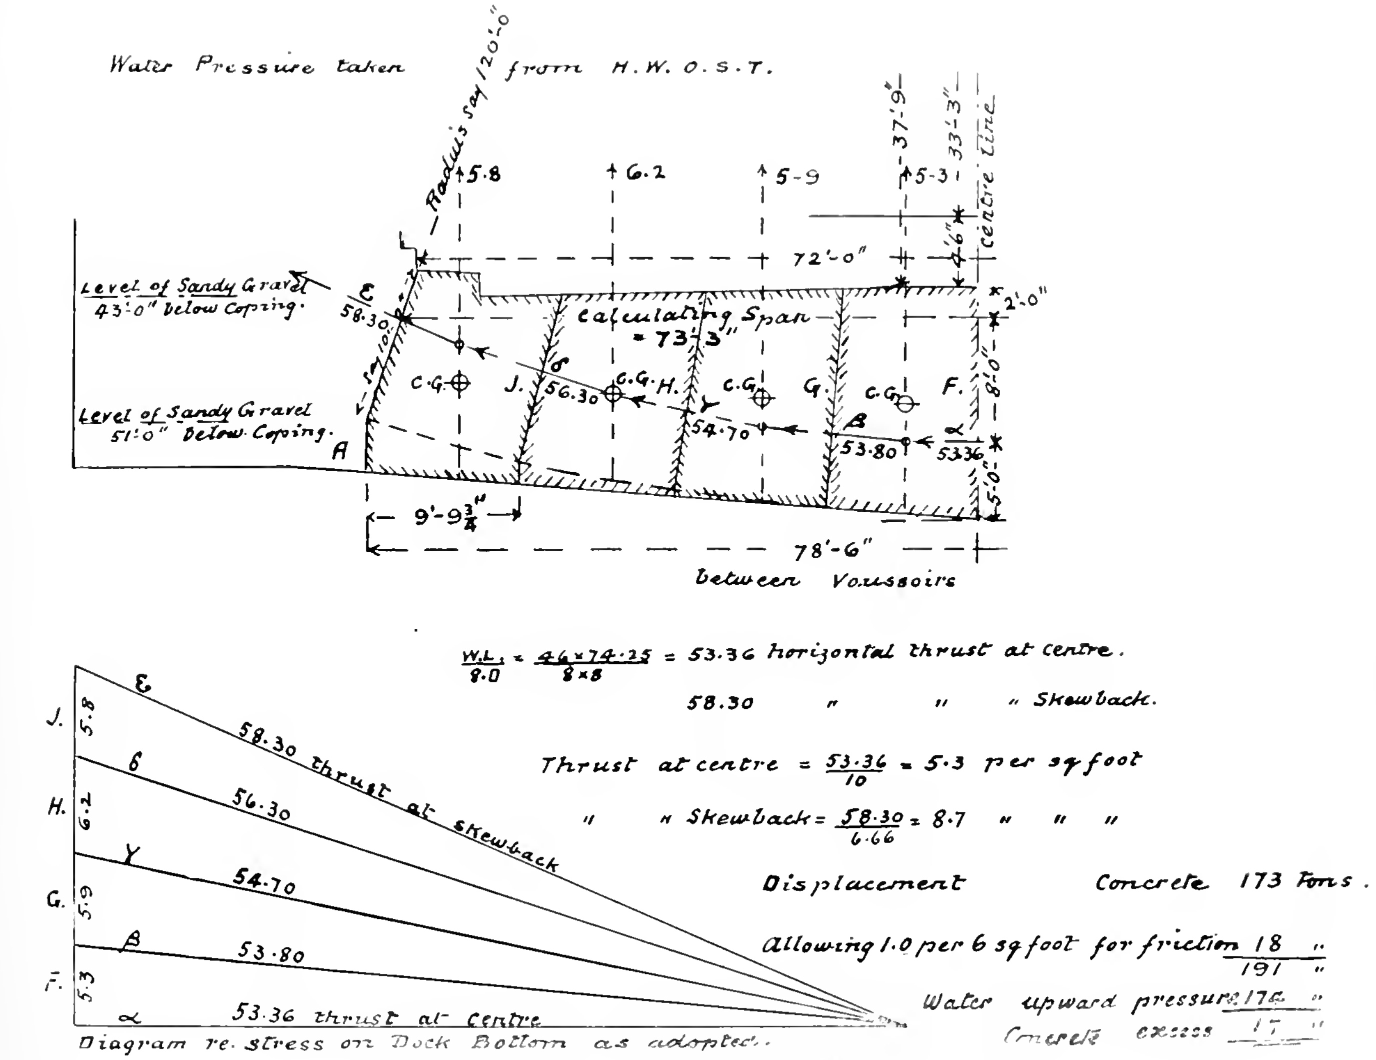

Fig. 3.—Stress Diagram of Dock Bottom; Fifteen Feet Thick at Centre.

thrust at skewback becomes $\frac{75}{5.3} = 14.0$ per sq. ft.

By the diagram for the side walls between B and C, it will be seen that the thrusts on the portions K and L of the wall become practically 75.0, and on the back of the wall 71 tons.

In respect to the upward pressure the difference between the concrete and water at section K is 0.5, and at section L is 17.5 for excess of concrete.

The total displacement is a follows:

Concrete and friction, as shown, equals	179 tons
Water, as shown, equals	174 tons
Difference equals	5 tons

foot, and in every way most satisfactory as regards displacement, which is of vital importance for the solidity and stability of the dock when completed. It may be mentioned that if a dock is too light when built in soft ground and wet, that it is liable to work upwards by hydrostatic pressure.

The construction of a dock must always be made of the very best material, and the ashlar well bonded and true in every respect, as much depends upon the workmanship.

For the purpose of affording access to the immersed parts of vessels, the ordinary graving dock, even at the present day, is the plan most commonly employed, and will continue to be preferred in places where there is a large rise and fall of tide, and where the ground is suitable for excavation.

In many parts of the world the rise and fall of the tide are sufficient to admit of a very large vessel being drawn

into a dock at high water, so as to be brought over the keel blocks, on which it then settles down as the tide recedes, and at low water the dock is left dry, and the vessel exposed for repairs, the sluices being then closed exclude the water, so that the succeeding tides cause no interruption to the work. Where the tide is but small, after the tide has receded, the water remaining in the dock has to be pumped out. This was done at the dock for which these calculations were made.

Where docks are hewn out of the solid rock and "faced" there are none of the dangers to be apprehended of settlement or of blowing up the bottom that exist where the dock is built in an excavation made in the earth, which is of an extremely treacherous character at river sides.

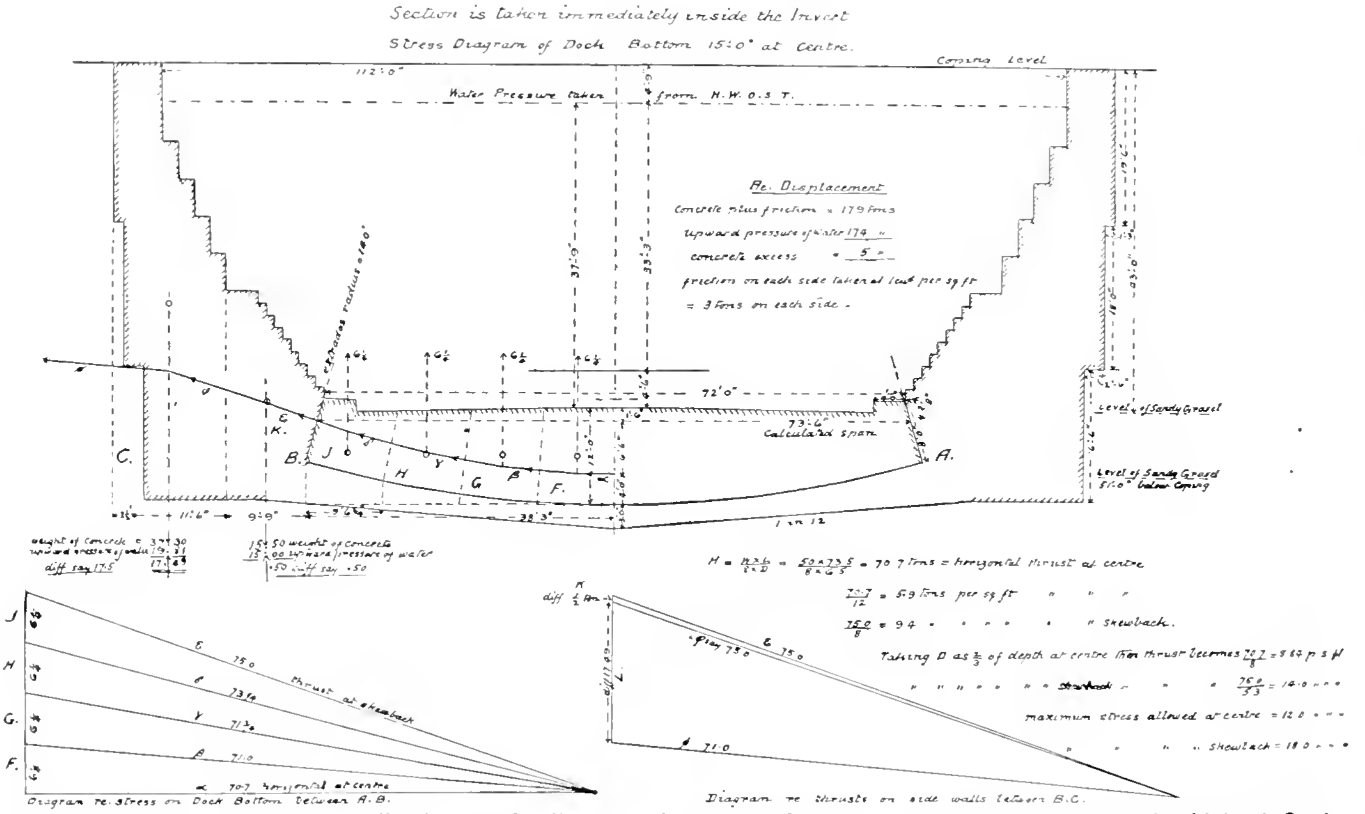

Fig. 4.—Section Taken Immediately Inside the Invert. Stress Diagram of Dock Bottom; 15 Feet Thick at Centre.

It is hoped that these calculations and remarks will be of service to those about to be engaged on work of this kind.

A NEW METHOD OF ELECTRO-PLATING.

A particularly interesting invention is that of "Voltite" by Mr. Arthur T. Firth, of New Zealand, which in brief is a method for the electro-plating of one metal on another by frictional precipitation. "The electro-plating of metals has grown rapidly to an industry of great importance," says Mr. Carl F. Woods, secretary of Arthur D. Little, Inc., of Boston, "but up to the present time there has been a great deal of economic waste owing to the practical difficulties in the way of replacing the electro-deposited metal which is lost by the friction of constant use. A number of attempts have been made to solve this problem and several patents have been issued, but in most instances the coating possible of application to the metal by this process is so thin as to be of little value.

A recent patent was issued for the deposition of nickel and other metals by friction which created considerable discussion in the electro-metallurgical world, but after a series of careful experiments it was found that the energy used in the process was so great in proportion to the results that the process possessed more theoretical than practical value.

The process invented by Mr. Firth is electrolytic like other electro-plating operations, but very much simplified and it is claimed for the invention that anyone of ordinary intelligence can operate the process successfully. The compound itself, water and the slight friction used in applying it form a voltaic action, the metallic powder forming the anode and the article on which it is to be deposited the cathode; hydrogen is developed, which reduces the salt to a metallic state upon the article itself. The operation is applicable to gold, silver, nickel, copper, tin and brass, and one of the most interesting applications is that of silver direct to steel. Perhaps the biggest field for its application lies in household use. The constant cleaning of silverware results in the removal of the deposited metal, whereas the use of "Voltite" is claimed to increase the thickness of the metal instead of decreasing it and at the same time to preserve the desired appearance of the article."

The coal production for 1912 is estimated at 550,000,000 tons by the United States Geological Survey. This amount compares with 496,221,168 tons for 1911, 392,722,635 tons for 1905, and smaller amounts for years before that. The production of anthracite shows a decrease on account of the suspension of operations during the wage controversy in April and May. There were, however, increases in almost all of the bituminous districts.

ROAD METALS.

The rapid advance of late years towards more perfect highway requirements has resulted in road metals and their study becoming an important branch of highway engineering. W. A. McLean, Provincial Engineer of Highways for Ontario, in his report to the government for the year past dealt with the subject as follows:—

Road metal, in the construction of macadam and gravel roads, serves three important purposes. It distributes the concentrated wheel load over a greater area of sub-soil; it forms a waterproof covering to protect the sub-soil from the softening effects of moisture; it forms a hard and durable wearing surface. The depth of material used, the method of placing it on the roadway, and the quality of materials used, should be proportionate to the three main factors stated. The concentrated wheel load controls largely the depth of material to be used; the necessity of having a waterproof coat emphasizes particularly the method of placing the road metal; and the need for a hard and durable covering is met principally by the quality of stone selected.

The foregoing rule is general, and while a greater depth of material makes a more waterproof surface, and will wear longer than will a thin coat; and while certain qualities of stone have better binding qualities, are more waterproof and will distribute the load at a wider angle, yet in a broad way the three requirements are responded to in the manner stated, viz., distributing power—depth of material; waterproofing—method of applying; durability under wear—quality of material.

Distributing Power—Depth of Material.—When a wagon carries in all two tons, it is apparent that each wheel places on the roadway, along a line which is the width of the wagon tire, a load of 1,000 pounds; if the wagon and its load weigh four tons, the concentrated load on a line the width of the wagon tire is 2,000 pounds. This may be assumed to be communicated to the roadway through a single cube of stone two inches square.

Experience shows that from this cube on a well consolidated roadway, the weight is distributed at an angle of about 45 degrees; and it may be shown that the area of subsoil over which the load is distributed, is equal to a square the side of which is twice the depth of the stone.

The supporting power of soil may be instanced by an extract from the Ontario Standard Specifications for Concrete Bridges, in which the bearing strength of soils, under foundations, is stated as follows:—

Rock in thick beds	25 tons per square foot
Strong gravel and coarse sand, dry..	8 tons per square foot
Compact sand or film clay, dry......	4 tons per square foot
Clay, moderately dry	2 tons per square foot
Clean, dry sand, not cemented.......	2 tons per square foot
Wet clay	1 ton per square foot
Quicksand and wet, yielding soils	0 to ½ ton per square foot

While the foregoing may be accepted as a safe guide for the depth of stone under heavy foundations, yet underneath a roadway, in which the protection from moisture is always insecure, safe loads under the macadam should not, with a proper factor of safety, be taken as exceeding one-half the amount stated.

From this analysis of the case, the importance of thoroughly draining the sub-soil becomes apparent; particularly with a view to securing the greatest possible strength of soil at the time of greatest danger, which is during the spring thaws and freshets. It becomes apparent also why four inches of stone placed on a strong, dry, gravel sub-soil may be as effective and durable as 12 inches of stone placed over a wet, slippery and poorly drained clay; and why a Telford or other strong foundation is at times essential over such a clay, and over a soft and marshy sub-soil. It explains why, in a given mile of road, the depth of stone and character of foundation may be varied half a dozen times to secure a roadway of uniform strength throughout the entire length.

Waterproofing—Method of Placing Stone.—A waterproof covering is one of the important features of a good macadam road, and this is largely obtained by the method of placing the stone. This requires a certain depth of material, not less than four inches on the strongest sub-soil, sufficient bonding material, which in waterbound macadam should be stone screenings; thorough consolidation by rolling, and a proper camber to shed water to the side gutters or drains

The depth of metal must in the first instance be proportioned to the strength of sub-soil and the concentrated wheel load, but a minimum depth of four inches is essential as that is the least depth that can be properly bonded by rolling.

Loose broken stone has about 50 per cent. of voids. If laid loosely on the road, without rolling and bonding, it will not shed water; but is merely a sieve through which rain and melting snow pass. The sub-soil is at once softened by moisture, and into this mud, the broken stone is forced by traffic, rutting the road and wasting the stone. To prevent this condition, sufficient fine material should be used on the road to fill the voids for some depth from the surface, and then rolled to thoroughly bond the stone, leaving a smooth water-tight surface from which rain is at once shed to the gutters.

Rolling takes an important place in making a water-tight surface. If not rolled, much damage to the road results before the metal becomes bonded by traffic, a considerable amount of the loose stone is driven into the mud and is largely wasted. Many gravel and stone roads in Ontario have had two or three feet of metal placed on them and forced into the mud in this way. With the voids filled with earth, the stone is of little use other than to strengthen the foundation in an inferior way. Economical construction requires a road crust of well-bonded stone laid in a well defined and uniform layer.

The camber of the road surface should be in keeping with the quality of the stone, and methods of construction. An average crown of one inch to the foot from side to centre is often specified, and this applies to the class of road ordinarily built in Ontario. This will provide for some settlement after construction. Except in the most expensive type of construction a new road should be given a crown that is too high, otherwise it will soon become too flat under traffic. It follows that in maintenance, the surface should be kept smooth and free from ruts and wheel-tracks in order that the flow of water from the surface will be immediate, and that none will have time to soak into the road.

Broken stone should be separated into grades according to size, the coarser stone to be placed in the bottom of the road and the finer at the top. This grading of stone is done by means of a rotary screen attached to the crusher. If the stone is placed in the road without being graded in this manner, the smaller stones wear away more rapidly than the larger and a rough surface results. Large stones at the surface, moreover, are more apt to become loose, to roll under the horses' feet or the wheels.

For common country roads using limestone, there should be placed in the roadbed:

(a) In the bottom a layer of stones such as are refused by a 2½-inch or 3-inch ring—"tailings."

(b) On this a coating of stones such as will pass through a 2½-inch or 3-inch ring.

(c) On this a sprinkling of screenings—that is, the dust and chips created by crushing, and including all that passes a 1-inch screen.

Course (c) should be only a thin covering, not more than enough to bond the stone when rolled. The main body of the road should be made of the grade (b).

Durability Under Wear—Quality of Stone.—The important properties of a good stone for roadmaking are (1) hardness, (2) toughness, (3) cementing properties, (4) and resistance to atmospheric action, including low absorptive qualities.

A stone may be very hard, and yet very brittle, so that toughness as well as hardness is necessary. A stone the dust of which will cement strongly, and re-cement when broken, makes a smoother and more waterproof road, and one which will distribute a concentrated wheel load at a wider angle. For this reason limestone, because of its cementing properties, is less inferior road metal than its softness would indicate. And some rocks, when first quarried, are hard and tough, yet through atmospheric action, decay rapidly. Rocks which absorb a large percentage of moisture are generally acted upon in this way by the combined action of moisture and frost. Low absorption is therefore desirable; and this is generally indicated by the weight of the stone, the heavier stone being more desirable in this respect.

The quality of stone is not a matter of name, as varieties of the same kind and even from the same quarry may differ greatly. Those who are familiar with limestone quarries know the great variation in hardness and toughness, between adjacent strata.

All things considered, the relative desirability of rocks available in Ontario for roadmaking may be placed in about the following order: (1) Trap; (2) Syenite; (3) Granite; (4) Limestone; (5) Schist; (6) Gneiss; (7) Quartzite; (8) Sandstone; (9) Slate; (10) Mica Schist; (11) Marble.

The name "trap," is one of very general application, and is usually applied to the black and green stones which, found in the fields, are known as "nigger-heads" and "hardheads." For some years, this material has been quarried at Georgian Bay, and shipped to cities in the United States. In older Ontario, the most convenient point at which it occurs is near Havelock, in Peterborough County, on the C.P.R. While trap is a most durable stone, yet consideration of economy and first cost will generally dictate the use of a softer and less durable stone of the locality in which the road is being built.

Throughout Western Ontario, limestone is common, and the greater mileage of roads is now being constructed of that material, since quarries are within easy access of almost any part of the province. Limestone ranges in quality from that which is very soft and decays rapidly, to that which is very tough, with strong cementing properties. If tough and close-grained, it is an excellent material for roads on which the amount of traffic is not excessive. In some parts of Eastern Ontario, granite, gneiss and schist are being used, and are proving very suitable. Granite is a harder and tougher stone than limestone, but its cementing properties are inferior; and a good practice when granite is employed, is to use limestone screenings to surface and bond the road.

Field stones are frequently used. Picked up from the fields, they are usually found to consist of fragments of trap, granite, gneiss, limestone, sandstone, and other varieties Owing to lack of uniformity, the serious deficiency of this material is that the softer stones wear more rapidly than the others, and in consequence a rougher surface is ultimately produced under traffic. Field stone, however, forms a good source of supply for road metal, and if obtainable in the locality, should generally be used in preference to stone shipped by rail.

Reliable tests of roadmaking material have been devised, relating to crushing strength, degree of toughness, degree of hardness, cementing properties; and absorption, indicated by weight or specific gravity. No test is so conclusive, however, as actual wear on the road, and old roads in the locality may be instructive.

Simple tests may also be applied. We may judge of the qualities of a stone by breaking with a hammer, wearing on a grindstone, crushing it in a blacksmith's vice, scratching with an iron nail, breaking small pieces with the fingers. A heavy stone is usually better than one that is light. A stone that breaks into cubical shapes is desirable, whilst one that breaks into thin, flat shapes is objectionable.

As previously suggested, the stone of the locality in which the road is being constructed should generally be used. Freight rates and additional cost of handling, will often add 50 per cent. to the cost of a road, as compared to the cost of a road made of stone obtained in the vicinity. It is usually better to accept an inferior stone, and resurface more frequently, than to pay freight rates on a more durable stone shipped in from a distance. This, however, will depend somewhat on traffic, and where travel is extremely heavy or constant, it may be in the interest of economy to pay freight rates for the more durable material. At times it is good practice to use soft material of the locality for the foundation of the road, and surface it with a tougher and more durable material, placing about 4 inches of the latter material on the surface.

SIDEWALK CONSTRUCTION POINTERS.

When it is proposed to lay a cement walk on a foundation that has been travelled over for several months, the entire surface should be loosened up, flooded, and thoroughly tamped down. This is common-sense, for, on a sub-base of this character, the foot travel generally follows one well-defined line, usually in the centre, which becomes solid and well packed and will not settle under additional weight; while the filling to either side of the centre, on being given additional weight, usually settles sufficiently to cause a crack lengthwise through the walk, unless the entire surface is first loosened and retamped to a uniform density.

A successful contractor states that in cold weather he mixes the concrete as dry as it is possible to have it, and then puts in the base in two courses, tamping each course separately—in this way obtaining a more uniform density in the concrete; and as a result he has never had to record a failure in his work. Better results will be obtained, and fewer walks with loose and cracked wearing surfaces would be seen, if workmen could be made to understand that a wearing surface will not adhere to, or form a bond with a base covered with loam or dirt which they have tracked over it either through carelessness or in order to save a few steps.

Clean-cut joints between slabs, and expansion joints adjoining the curbs at streets and alley returns and at frequent intervals in long stretches of walk, are absolutely necessary if broken curb-stones and broken slabs in the walks are to be avoided. Expansion joints at street and alley returns can be eliminated by constructing the curbing with a recess into which the sidewalk slab may be laid.

ELECTROLYSIS FROM STRAY ELECTRIC CURRENTS.

By A. F. Ganz, M.E.

(Continued from page 521 of last week's issue).

A number of investigations have been made to determine the effect of electrolysis on iron or steel embedded in concrete, and these have shown that where the iron is an anode —that is, where current passes from the iron to the concrete —this effect is to corrode the iron and form rust which occupies more space than the iron, causing expansion which finally cracks the concrete. The most recent and most complete investigation of this kind is one made at the Bureau of Standards, Washington, and described in a paper by E. B. Rosa, Burton McCollum and O. S. Peters, presented before the National Association of Cement Users in Pittsburgh, December, 1912. These recent experiments have shown that an extremely small current, flowing from an iron rod to a surrounding block of concrete, will produce enough corrosion to crack the concrete in the course of one or two years. These investigations have also shown that the presence of even a fraction of 1 per cent. of salt or of other chlorides may increase the action of electrolysis on iron embedded in concrete over 100 fold. They have also shown that, where the iron is a cathode—that is, where current passes from concrete to the iron—a softening of the concrete is produced in the immediate neighborhood of the iron which eventually destroys the bond between the concrete and the iron. The introduction in recent years, of buildings constructed entirely of reinforced concrete, has raised the question of the possible damage to such buildings from electrolysis of the reinforcing steel. Where reinforced concrete structures are located near railway power stations which have a grounded negative bus-bar, there may be a considerable potential

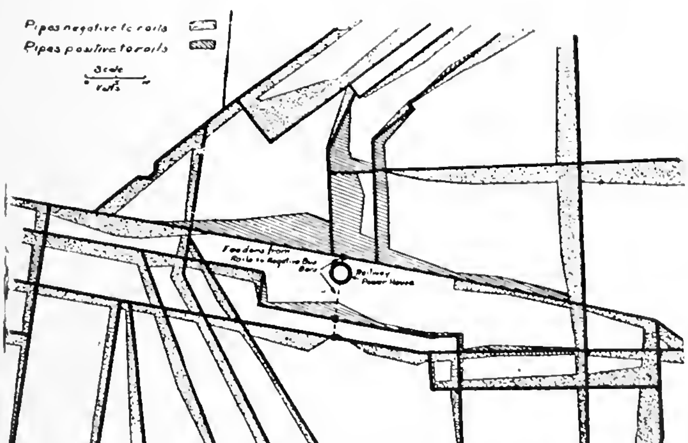

Fig. 3.—Typical Potential Survey of City, Showing Electric Railway Tracks and Potentials of Underground Pipes to Trolley Rails.

gradient through the ground upon which the concrete building stands, and in such cases it is possible that currents may flow through such a reinforced concrete building. These currents, although very small in magnitude, may cause a great deal of damage because the successive elements of steel and concrete form a series circuit, and damage will result at every point where current flows from steel to concrete or from concrete to steel. The most likely means of entrance or exit of stray electric currents, into or out of such buildings, is by underground gas or water pipes, or by foundations of concrete or of steel. In the light of these recent investigations it would, therefore, seem a wise precaution in such buildings to install insulating joints in every pipe which connects to the building from ground. In the paper above referred to it is also suggested that granite blocks might be interposed between the building footings and soil so as to prevent stray currents from flowing into and out of the building through the footings.

Electrolysis Surveys.—The diagram illustrated in Fig. 2 shows that voltage drop in the rail produces stray current through ground and through underground pipes, and pro-

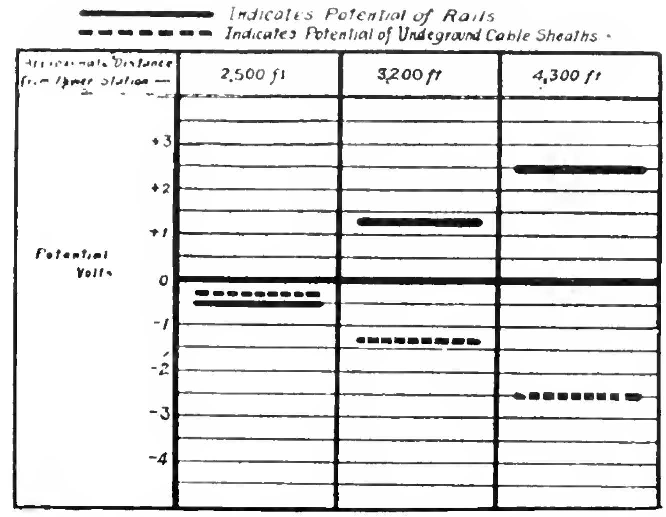

Fig. 4.—Diagram Showing Route of Potentials with Pipes Taken as the Datum or Zero Potential.

duces potential differences between pipe and rails, making the pipe appear positive in potential where current leaves the pipe, and negative in potential where current flows to the pipe. The first step in an electrolysis survey of a town is, therefore, to measure potential differences between pipes and rails, at a number of points throughout every street on which there are electric railways. Where the main itself is not exposed, connections to the pipes for these voltmeter measurements may be obtained by means of service pipe or drip connections. Such connections are generally satisfactory because the voltmeter itself has a high resistance and, therefore, takes only a very small current. Readings are taken at each point every 10 seconds for 10 or 20 minutes, depending upon the car schedules, and the maximum, minimum and average results of the readings recorded. A convenient instrument for these potential readings, which can also be used for the drop measurements described below, is a Weston, Model 1, combination millivoltmeter and voltmeter, with its zero in the centre of the scale, and having ranges of 5, 50 and 500 millivolts and of 5 and 50 volts. These instruments are made with very high resistances, so as to be particularly applicable to electrolysis testing.

After such potential measurements have been made throughout the principal streets of a town, they are then conveniently plotted on a skeleton map of the town, in which the trolley lines are shown. The potentials of the pipes referred to the rails are laid off normal to the lines representing the railway tracks to some convenient scale, usually 1 inch = 10 volts. The ends of these potential lines are then connected, and the included areas are colored red where the pipes are positive in potential to the rails, and blue where the pipes are negative in potential. In Fig. 3 is shown a typical potential survey map, in which the negative areas are

shown by dots, and the positive areas by section lines, instead of by blue and red areas. It will be noted that, in the neighborhood of the railway power station, the pipes are highly positive to the rails, and at points distant from this station they are negative to the rails. The existence of potential differences between pipes and rails is, however, no conclusive evidence of stray currents on the pipes; they indicate at what points current is probably flowing from rails to pipes and from pipes to rails.

Where there are a number of underground metallic structures which may be affected by electrolysis, it is desirable to make simultaneous measurements of potential difference between the rails and each of these structures. The average values of these simultaneous potential measurements may then be conveniently plotted on a diagram in which the

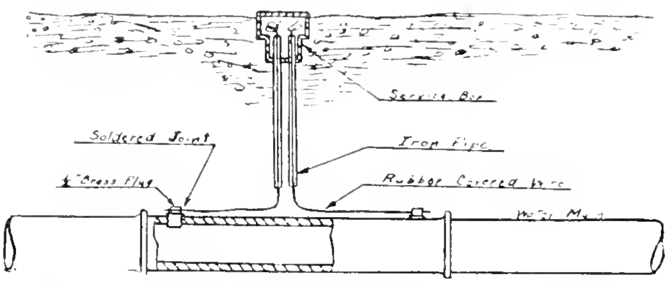

Fig. 5.—Permanent Electrical Test Wire from Surface of Street to Pipe.

potential of any one of the structures is taken as the datum or zero of potential. In Fig. 4 is shown a set of diagrams giving the relative potentials between water pipes, trolley rails and underground cable sheaths, at 3 points along a given street. In this diagram the water pipes are assumed as the datum or zero of potential, and the potentials which are positive to the pipes are laid off above the axis, while those which are negative to the pipes are laid off below the axis, to the scale indicated in the diagram. In the case shown in Fig. 4, the cable sheaths are connected to the railway return conductors near the railway power station. It will be noted that, at the point nearest the power station, the water pipes are positive both to the cable sheaths and to the rails, and that the cable sheaths are also slightly positive to the rails. At greater distances from the power station the rails become increasingly positive to the water pipes, while the cable sheaths become increasingly negative to the pipes. The potential difference between the rails and the cable sheaths increases very rapidly with increasing distance from the power station, as is seen from Fig. 4.

The next step in the survey is to measure drop between drip or service connections, which will indicate the probable existence and direction of current flow on the pipes. Such drop measurements cannot, however, be used for calculating the amount of current on the pipes. To determine the actual current flowing it is necessary to measure the drop between two points on a continuous length of pipe by means of a millivoltmeter. This drop, expressed in volts, divided by the assumed or measured resistance in ohms of the included length of pipe, gives the current expressed in amperes. A convenient table giving the current in amperes for 1 millivolt drop in 1 foot of standard wrought iron, steel and cast iron pipes is appended to this paper. To find the current flowing on a pipe corresponding to a given drop in millivolts for a measured length, multiply the amperes given in the table for 1 millivolt drop for 1 foot by the number of millivolts drop measured, and divide by the included length of pipe in feet. To measure this drop it is necessary to expose the pipe and to make good electrical contact between the millivoltmeter leads and the pipe. A satisfactory method is to use a pointed piece of steel, about the size of an ordinary lead pencil, fastened in a wooden handle, with a flexible connecting wire soldered to it inside of the latter. The pointed steel is then pressed against a bright spot or into a filled notch on the pipe. A still better contact is obtained by soldering the connecting wire directly to the pipe or to a brass plug screwed into the pipe, which is particularly advantageous when readings are to be taken over a considerable time. When such contact wires have been soldered to a continuous length of pipe it is common to use rubber covered wires, bringing them to the surface of the street, leaving the ends in drip or service boxes, which then form permanent test stations for electrical measurements. This is exceedingly convenient, for it is then possible to make current measurements on the pipe without again digging an excavation. Such permanent contact wires for electrical tests are illustrated in Fig. 5.

It should be noted that small potential differences, such as 0.1 millivolt or less, may be caused by local galvanic or thermal action. Where such small values are found in a test for drop on a pipe a careful investigation should, therefore, be made to ascertain whether the observed potential difference is actually drop due to current flow or is due to local causes. The writer has found that such local potential differences are a frequent source of error when such tests are made by persons who are not accustomed to making accurate electrical measurements.

When drop measurements between services and current measurements on pipes have been generally made on a piping system, the results are conveniently plotted on a skeleton

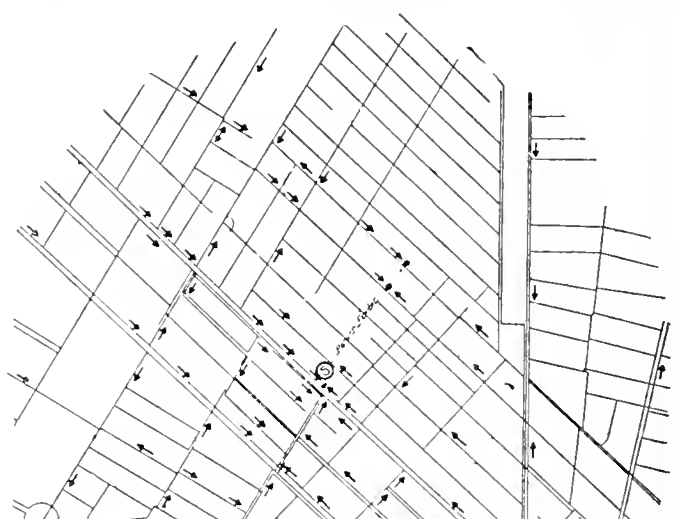

Fig. 6.—Typical Current Survey, Showing Underground Mains and Stray Currents Flowing on Mains.

map of the city in which the pipe lines are shown and the current flowing on these pipes are indicated by arrows. A typical current survey map of a portion of a city is shown in Fig. 6. It is seen that here the currents on the pipes flow in a general direction towards the railway substation.

Since current destroys the pipe only where it leaves the pipe for soil, it is important to know where the current does

leave the pipe. Current measurements on pipes are, therefore, frequently made at two or more stations simultaneously in order to determine the change of current on the pipe between the stations. In Fig. 7 simultaneous current measurements made at two stations on a pipe are shown plotted where there is no change of current between the stations. In Fig. 8 simultaneous current measurements at two stations on a pipe where there is a considerable loss of current between the stations are likewise shown.

In order to determine the characteristic variations of a potential difference between pipe and rails, or of current flow on a pipe, 24-hour records of such potential difference, (or of current flow) may be obtained by means of a special Bristol, smoked-chart, recording instrument. This recorder has for its measuring system a sensitive Western millivoltmeter, and may be provided with a number of ranges. It is convenient to have the instrument provided with its zero in the centre of the scale, and with ranges of 5, 50 and 500 millivolts, and of 5 and 50 volts. Shunts of any desired ampere range can also be used in connection with the recording millivoltmeter, and the instrument used as a recording ammeter of a corresponding range. Convenient shunts for this are ordinary switchboard shunts adjusted for 50 millivolts drop, with rated capacities of 5, 50 and 500 amperes. Such potential and current records are conveniently plotted from these charts in rectangular co-ordinates. Sample 24-hour records of current on a pipe plotted in rectangular co-ordinates for one week are shown in Fig. 9, from which it will be seen that the current records for weekdays are practically alike, and show morning and early evening peaks. The record for Sunday is, however, very different and shows a very large peak throughout the whole afternoon. This is accounted for by the fact that the neighboring trolleys were carrying large crowds of excursionists on Sunday outings. By means of such 24-hour records it is often possible to positively identify the source of current flowing on a pipe as railway current from its similarity with the railway load curves. Twenty-four-hour records of current flowing on pipes may also be

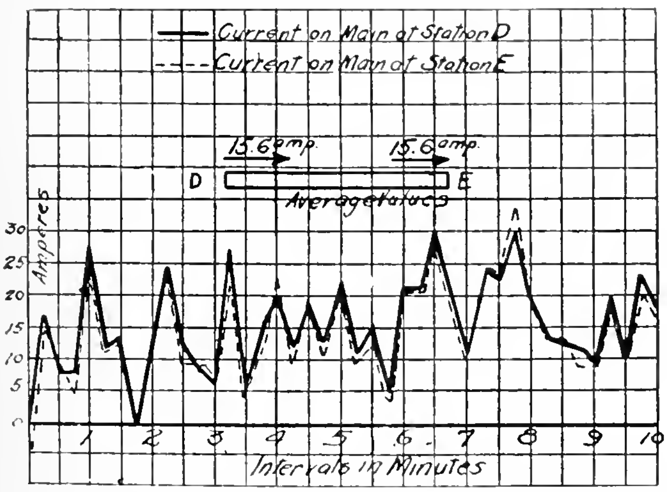

Fig. 7.—Simultaneous Current Measurements Where There is no Change in Current Between Stations.

obtained at two or more stations simultaneously, and the change of current between the stations for the 24 hours determined.

It is possible to trace the path of current flow through ground by measuring potential differences between points in the ground. Where small potential differences are measured between two points in ground and iron rods are used as electrodes, entirely incorrect results may be obtained, because of possible differences in polarization voltages at the surfaces of the electrodes. To overcome this difficulty, a "non-polarizable electrode" was devised by Prof. Haber. This consists of a glass tube, with a porous cup cemented to one end, containing a saturated solution of zinc sulphate, and of a zinc rod dipping into the solution. A wire is brought out from this zinc rod through a cork in the top of the tube. To make contact to ground with this electrode the porous cup is pressed against the part of the ground at which the potential is to be measured, thus establishing contact between the ground and the zinc sulphate solution. This establishment

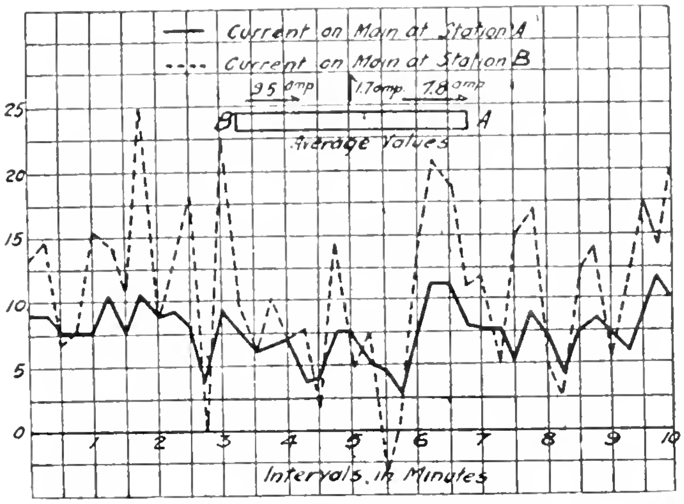

Fig. 8.—Simultaneous Current Measurements Where There is Change in Currents Between Stations.

of electrolytic contact between ground and the zinc sulphate solution eliminates polarization voltages. The polarization voltage between the zinc rod and the zinc sulphate solution, which is a definite known voltage, must be allowed for when using this electrode. It is also essential that, when this electrode is used, the potential measurements be made by means of zero methods, and not with indicating volt-meters, because of the very high contact resistance produced with this electrode.

It is often also desirable to measure directly the flow of current through ground, as between a pipe and rails, or between two pipes. This can be done by means of an earth ammeter, which was also devised by Prof. Haber. This consists of a wooden frame with two copper plates insulated from each other by a plate of mica or glass. Insulated copper wires are brought out from the two copper plates, and these wires are connected to an ammeter. To use the frame, the two copper plates are, first, coated with a paste made of copper sulphate and a 20 per cent. sulphuric acid solution. A wetted piece of parchment paper is then laid over the paste, and the remainder of the frame filled with soil from the excavation where the current flow through ground is to be measured. The frame is then buried in ground normal to the direction of the current flow to be measured, and the ammeter will indicate the current flow which is intercepted by the buried frame. The object of the copper sulphate paste on each plate is to equalize polarization potentials at the surfaces of the copper plates. This earth ammeter is also well suited for measuring current flow between pipe and ground. For this purpose the frame is buried in the ground one or two inches from and parallel to the pipe. Measurement of current flow from a pipe thus made can be used to form an estimate of the probable amount of electrolytic damage to the pipe, and in cases where corrosion has taken place,

this kind of test will often serve as evidence that the corrosion has been caused at least in part by stray currents leaving the pipe. By using a recording instrument in connection with the earth ammeter, the characteristic variations of the current leaving a pipe can also be determined, and in this way the identity of the current can often be established.

From a study of the results of the survey it can be determined where current is leaving the piping. At a number of such points excavations should then be made and the exposed pipe examined with a test hammer for electrolytic corrosion. Where such corrosion and pitting are found at points where current is found leaving the pipe, it may be taken as evidence that the destruction was caused by electrolysis, because it has been conclusively proven that current cannot leave iron for surrounding soil without producing corresponding destruction of the iron.

Regarding the use and value of an electrolysis survey, it must be remembered that the object of the survey is to indicate the existence or non-existence of stray electric currents upon a piping system, and to determine where such currents flow on to the pipes and from the pipes. I have had occasion to examine a large number of electrolysis surveys and have found that many of these consist exclusively of voltmeter readings, and often these voltmeter readings are only made with reference to the rails. Such readings by themselves do not afford a measure of electrolytic danger.

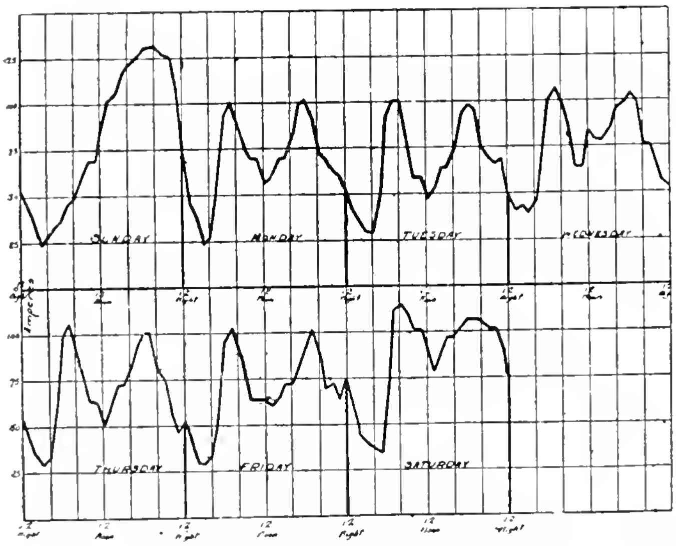

Fig. 9.—Stray Currents on Water Main Averaged from 24-Hour Record and Plotted for Week.

Potential measurements should be made to all underground structures. Measurements of current flow on pipes are also essential in an electrolysis survey because all current which flows on a pipe must leave it, and the amount of damage produced is proportional to the total current which leaves the pipe. I have seen some reports, on the other hand, where it is stated that the current on a given pipe is zero, but where the instruments and methods employed were not sufficiently sensitive to detect current as large as two or three amperes, and where, therefore, the conclusion of zero current is not warranted. From a complete and properly analyzed electrolysis survey, a great deal of good can generally be accomplished. It will not always be possible to remove all stray currents from the pipes, but measures will be indicated by which the conditions can be greatly improved, and points of greatest danger will be located. If then trouble does occur at a later time at these points, the electrolysis survey may be most valuable in affording proof of the destruction of the property from railway currents, and may be the means of compelling the railroad company not only to pay for the damage, but also to make improvements in its return system so as to avoid the recurrence of such damage. I know of a number of electric railroad companies who are regularly paying for damage caused by electrolysis to piping systems. The knowledge that a pipe-owning company is making electrolysis tests and is keeping watch on the situation, also has a strong moral effect on the electric railroads.

(To be continued).

HEMLOCK AND ITS USES.

The British Columbia Forest Service has data showing that western hemlock, which is being cut in increasing quantities on the coast, is a much more valuable timber than was heretofore thought. The sale is increasing throughout the province, some companies having placed it on the prairie market in successful competition with Douglas fir, on account of the lower freight rate and the relatively smaller danger of splitting in nailing. This latter reason makes it acceptable for joining and siding. At present the principal use of hemlock in British Columbia is in pulp manufacture, great areas in the north being cut over to supply this growing industry.

Authentic data are lacking with regard to the durability of western hemlock as compared with Douglas fir and other woods. The general impression is that Douglas fir is the more durable.

A few experiments made to determine the adaptability of western hemlock to treatment with liquid preservatives indicate that, as compared to Douglas fir, it offers about the same resistance to impregnation across the grain; but that it is easier to penetrate along the grain.

Hemlock is well suited for use in all but the heaviest construction work, as shown by results of tests which have been made, but up to the present time it has had a limited use in bridges and trestles. It has been used in some instances for caisson construction.

A considerable amount is cut into cross-ties. Many of the western railroads use Douglas fir, western larch, redwood and western hemlock exclusively for tie material. A large percentage of those ties are laid without preservative treatment. Occasionally it is cut into telephone or telegraph poles, but its use in this form has been very limited. It has the requisite strength for pole use and grows in such dimensions as to make it very suitable for this class of work. With a good treatment with some efficient preserving fluid it should give good service as a pole material.

Though practically all piling in the west is of Douglas fir, western hemlock is used to a limited extent, however, for this class of work and has apparently given satisfaction.

In house construction it is used a great deal as a framing material. For this class of work it serves as well as Douglas fir, and locally commands the same price.

When cut edge grain it makes good flooring material. It finishes smoothly on account of the uniform texture of the wood and it also wears evenly. It is not suitable for use in damp places on account of its tendency to warp under such conditions.

As a finish lumber it has the advantage of containing practically no pitch; it has a beautiful grain, works smoothly, takes stain readily, and when properly dried, will not shrink or swell materially under normal conditions. It presents a comparatively hard surface and consequently does not mar easily.

Western hemlock slabs and edgings are manufactured into lath, and as a lath material it is equally as valuable as Douglas fir or other wood. In this form there is no distinction made as to species, all pieces of a suitable form to make lath being thrown in together and used indiscriminately.

It is used to a large extent for barrels and boxes for shipping foodstuffs. For this purpose it serves admirably, since the wood is odorless and tasteless. A good development along this line may be looked for when consumers realize the value of the wood, and cease wasting it as at present.

PAINT AS AN ENGINEERING MATERIAL.*

By Dr. Maximilian Toch.

The progress that paint chemistry has made since 1905 is by far greater than the progress that has been made from its earliest invention up to that date. It is very difficult for me to imagine that my first book on "The Chemistry of Paints" stimulated others to continue the work which I had started, and if the little that I have done to enlighten the manufacturers and consumers has brought about the progressive results, I certainly have been rewarded for all the work I have ever done on the subject.

The first skyscraper ever built was the Gillender Building, corner of Wall and Nassau Streets, which was razed two years ago. Chemists knew before this building was demolished that linseed oil paint was not the best material for the protection of steel of large buildings. The question as to whether our monumental buildings are permanent has been a source of great worry to many chemists and engineers. Fortunately, if any of the steel contained in buildings like the Woolworth Building, Metropolitan Tower, the Singer Tower and dozens of others should show signs of corrosion and disintegration, the process is so slow that preventive methods could be applied, for a beam could not corrode in a masonry wall without cracking or bulging the wall. I have in mind one building in Maiden Lane where this actually occurred, and the wall of the fifteenth floor was cut away, the corroded beam exposed, thoroughly scraped, painted and reinforced, surrounded by concrete, and the brick wall replaced.

From the street level up every skyscraper in the world is safe, but from the street level to the grillage beams is the dangerous point. Of course, a small building could be "jacked up" and a grillage beam replaced. In a large building, two of which I have in mind, where the grillages were affected by leaky electrical currents, the foundation beams were uncovered, scraped clean and painted, and then a grout of almost pure neat cement injected all over the surface. Of course, it would be out of the question to "jack up" a building like the Woolworth Building or the Metropolitan Life, even though Archimides said: "Give me a fulcrum and I will move the world," but it is a source of great satisfaction to know that engineers and architects in charge of these buildings have taken sufficient precautions to prevent any danger whatever, either from electrolysis by means of stray currents, or from corrosion by means of dampness, and all the sensational talk about danger of the newer skyscrapers not lasting fifty years is utter "rot," for not one of these buildings is so constructed that should any danger result it could not be remedied in due time.

* Abstract of address before the American Chemical Society.

That paint is an engineering material of incalculable value is evidenced by the fact that none of our bridges would last ten years if they were not repeatedly painted and watched. The railroads are much wider awake to this condition than the municipal governments. Politics and paint do not mix very well, as is evidenced by the condition of some of our bridges. It may be very safely said, that all of our elevated railroads in New York City and all of the battleships of the United States government depend for their life on the frequency with which they are painted. My examination of the battleship "Maine" when the wreck was uncovered last year showed that not a vestige of paint remained, and it furthermore showed that wherever steel and copper, or iron and bronze were in close proximity an electric battery was formed and the iron was completely dissolved.

This, then, leads me to the general subject of the more modern type of paint containing no saponifiable oil, but made entirely of such materials as are unaffected by alkali, and such tremendous structures as the Pennsylvania Terminal, in New York City, the Metropolitan Life Tower, and Building, the Woolworth Building, and the newest and largest of all engineering structures—the New York and Connecting Railway not yet begun—are types of modern structures in which the old-time linseed oil paints have been superseded and protected by more scientific paints. Perhaps the most remarkable fact in all these instances is that fifteen years ago perhaps one concern in the United States started a campaign of education and convinced many prominent and well-known engineers that paint was an engineering material, and not one material is suitable for all purposes, with the result that the paint industry has been raised from empiricism to an exact science. Ten years ago nobody dreamed of painting cement floors or cement walls on account of the tradition that it was impossible to paint concrete. It is quite true that it is impossible to paint new concrete with a linseed oil paint owing to the resulting chemical action of the combination of the oil and the lime in the concrete, and yet when the first patent was taken out on this subject nobody infringed because it was believed that it could not be a success, but after it was demonstrated that this was a success it was the same story as "Columbus and the egg," and everybody iimitated and made a success of it.

The United States Navy, through one of its most efficient naval constructors, Mr. Henry Williams, has kept pace with the paint progress, and Mr. Henry Williams' article, a treatise on the subject of "Newer Paint Conditions in the United States Navy," read before the Eighth International Congress of Applied Chemistry, was copied not only by every paper in the United States, but was heralded throughout Europe, and to those who want to know what excellent progress has been made in this branch of the government, I would refer to his excellent treatise on the subject which is to be found in the transactions of the Eighth International Congress of Applied Chemistry.

Before closing my remarks and showing the illustrations I have taken for this lecture, I must say a few words regarding the sensational statements that have appeared lately in the press concerning the poisonous effects of white lead on workmen. It is very true that lead injected or absorbed in any form into the system produces plumbism, but the matter is not as serious as sensational newspaper writers have made it. All this talk about putty powder poisoning men in glass polishing factories is practically untrue, for putty powder happens to be tin oxide or a mixture of tin oxide and precipitated barium sulphate. The use of lead compounds in the preparation of wall papers is just as ridiculous as the arseni-

cal poisoning which was supposed to have injured so many operatives who used green pigments for printing wall paper designs. It turned out, of course afterwards, that the green pigments were chrome pigments, and the percentage of arsenic contained in the aniline dyes was so minute that even if they had dusted off it is a question whether they would have done any harm, for the pigments which are printed on wall paper are never released from their base.

The precautions that are taken in the white lead factories in the United States are so great that the plumbism which results is due to a large extent to the carelessness of the workmen themselves. As far as my personal experience goes, it is the hardest thing in the world for us to educate illiterate workmen that they must wash their hands before they eat, and the State is now distributing circulars printed in various languages notifying workmen that it is illegal for an employer or an employee to permit food to be consumed where these materials are manufactured. We are all well aware that the transportation of high explosives is exceedingly dangerous. There have been some frightful holocausts resulting from explosions in transit, and yet it is safe to say that any civilized country would go back untold and countless years if laws were enacted prohibiting the transportation of explosives, for coal metals and minerals would lie practically untouched in the ground; and the only safeguard is that, knowing that the materials are necessary for the excavation of the riches of the earth, due care should be taken in their transportation. Practically the same is true in the manufacture of any hazardous material, and therefore sensational and irresponsible statements pertaining to the manufacture of any chemical, whether it be lead or nitroglycerine, are to be decried.

COSTS OF CONCRETE PAVEMENT.

We publish below a table taken from the Journal of the American Society of Engineering Contractors, showing the amount, average price, and some details of concrete pavements constructed in a number of American cities:—

	Sq. yd.	Av. price per sq. yd., including grading.	Guarantee. Years.	Total thickness of pavement. Inches.	Proportions.

The three great liners of about 50,000 tons each, which have been ordered by the Hamburg-American line, says an English exchange, are going to be fitted out with telephone exchanges of the most modern type, to which each cabin will be connected. This marks a very appreciable and further addition to the luxury of trans-oceanic travel.

THE ELECTRIFICATION OF STEAM RAILWAYS.*

By N. W. Storer.

A discussion of the subject selected for this meeting is one which almost invariably arouses the greatest interest. It is not because it is an electrical subject nor because it is about railways. It is because it is a subject that concerns every one who travels, for all such men have been subjected to the discomfort of riding behind a steam locomotive and are interested in everything that offers an improvement. Mr. Dooley says that any one may experience all the delights of riding in a sleeping car without leaving home. His advice is: "Throw a $2.00 bill out of the window, put a cinder in your eye and spend the night on the top shelf of your darkest closet." This is probably a slight exaggeration of the joys of present-day travelling, not due entirely to the steam locomotive, and although only the cinder and its attendant smoke and dirt can be eliminated from this picture by the use of the electric locomotive, most people are anxious to have the steam engine discarded even before they have seen an electric locomotive. When one has experienced the happiness of riding behind an electric on a hot day in the summer with all windows up and no smoke and cinders, he is ever after a convert to the electric.

The belief in the unbounded possibility of electricity has led to the idea that it is only a matter of a few years before all the steam locomotives will be relegated to the scrap heap. I used to share the belief, but the more I learn of the subject, the more respect I have for the steam locomotive and the work it is daily performing, and the greater the task of supplanting it with the electric appears to be; not that we are doubtful as to the ability of the electric locomotive to do the work, for we are certain that almost any railway can handle more traffic and do it better when operated by electricity than by steam. What, then, is the reason for doubting the speedy and general substitution of electricity for steam? Simply that the traffic on most railways at the present time would not pay for the large initial investment necessary for operating it by electricity.

A steam locomotive is an independent power unit requiring supplies only of fuel and water at intervals along the road. The electric locomotive is in itself powerless. It must have a power house back of it, with transmission lines to carry the power to it wherever it may be.

As the electric locomotive itself is much more expensive than the steam engine, and the power house and distribution system cost a great deal more, the investment for operating a heavy railroad by electricity must, therefore, be relatively very large, and unless the frequency of trains is high enough to maintain a good load factor on the line, substations and power house, it can scarcely pay. In other words, electric operation will pay if you can keep the apparatus working a reasonable percentage of the time, but will not pay if the percentage is small. A bank cannot pay interest on deposits when 90 per cent. of them are locked up in a safe. Similarly, a man who has a high-priced automobile that is run only 1,000 miles per annum, is paying a very high price per mile; much higher than the man whose machine covers 10,000 miles. Any apparatus must be used in order to make it pay for itself.

In comparing the cost of electric with steam locomotives, one railway official went so far as to say that the electric locomotives used to haul their trains cost not $35,000 each, which was the contract price for them, but $100,000 each, which was the cost of the entire installation, divided by the number of locomotives. This might appear to be the case, but it is not strictly correct, unless the cost of all the roundhouses, machine shops, coal handling and distributing apparatus, water tanks, etc., be included in the cost of the steam locomotives. Even that, however, would leave the cost of the latter motive power only a fraction of that of the electric. Under such a handicap, it cannot be expected that the railroads, which are laboring under great financial difficulties at the present time, will be able to electrify their lines except under conditions that absolutely require it or offer exceptional advantages.

Compulsory conditions are sometimes imposed by legislation to force a railroad to electrify to abate the danger and discomfort of operating steam locomotives through long tunnels. This was the immediate cause of the adoption of electricity as a motive power by the New York Central and the New Haven Railroads, for the entrance to New York City. This electrification cost a tremendous amount, but it has resulted in a most magnificent terminal, increased comfort and safety to the travelling public, and last but not least, in increased value of real estate owned by the railroads, which bid fair to make the electrification a paying investment. If this last proves to be really true, it will be most important, as it will make electrification much more attractive to the far-seeing railway officials and will result eventually in the electrification of the terminals in all the large cities.

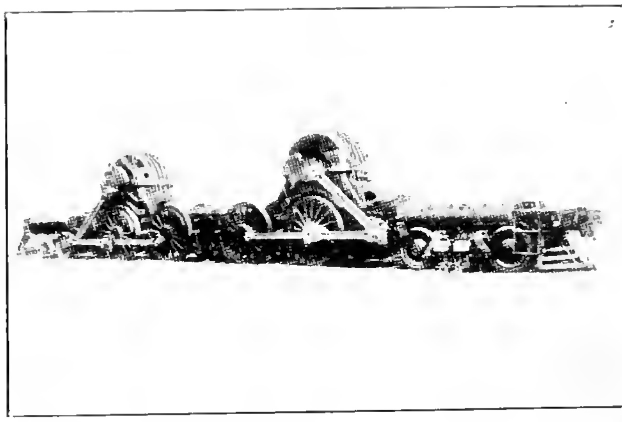

Fig. 1.—Running Gear and Motors, Pennsylvania Locomotive.

Beginning with the B. & O. R.R. at Baltimore, in 1895, a number of railroads have electrified tunnels which were a constant menace to the health and lives of the passengers and train crews. The St. Clair tunnel of the Grand Trunk Railway was electrified in 1906, and since then the Detroit River tunnel of the Michigan Central, the Cascade tunnel of the Great Northern, the Hoosac of the Boston & Maine, the Pennsylvania tunnel leading to the great terminal in New York City, have all been electrified in this country and are operating with great success, handling both passenger trains and the heaviest freight trains on both heavy grades and level track. These tunnels, in all of which, except the Pennsylvania, steam engines were originally operated, will be remembered by travellers as the places where every one was formerly nearly stifled. Now, either in the hottest summer day or the coldest of winter weather, the tunnel is welcomed as being the most comfortable part of the ride.

Another phase of the situation that is now receiving a great deal of attention is on the mountain grades where the heavy freight trains crawl up at from 5 to 10 miles per hour,

---

* Abstract of paper read before the Cleveland Engineering Society.

and the passenger trains crawl up at from 10 to 20 miles per hour. These grades always form the "neck of the bottle," and limit the amount of traffic that can be handled by an entire road. Even if it cost a great deal more to operate such grades by electricity, it would pay large dividends on the investment by increasing the capacity of the entire road.

Some one may wish to inquire how this electrification will increase the capacity of the entire road. It is effected by increasing the speed both on the up-grade and the down-grade, and by the greater reliability of service. On electrified divisions, the heaviest freight trains of 2,000 to 3,000 tons trailing load can readily be hauled up a grade of 2 per cent. by electric locomotives at speeds of 15 to 20 miles per hour, while the speed with steam locomotives would be usually from 5 to 8 miles per hour. This is possible because the electric locomotive has the power house back of it, but does not have to haul it up the hill. At speeds of 15 to 20 miles per hour it will have all the weight on drivers, and usually only as much as is necessary for adhesion. This being the case it can haul the trains at 20 miles per hour just as efficiently as at 10 miles per hour.

The steam engine, on the other hand, must haul its entire power plant up with it, and consequently, the higher the speed at which it operates up a grade, the less load it can pull, so that the economical speed is very soon reached. This appears to be 10 miles per hour, or less, for a 2 per cent. grade with heavy freight trains.

As the electric locomotive can take a train up a heavy grade much faster on account of its greater power, so it can take a train down the grade at a much higher speed because the motors can hold the train from accelerating by regenerating power and putting it back into the line to help some other train up the grade, or by using it up in a resistance on the locomotive. This saves the brake shoes for use in stopping the train only and thereby eliminates a great deal of the danger of taking trains down grades. Incidentally, the saving in power may be as much as 25 per cent., and the saving in brake shoes and general wear and tear of the equipment will also amount to a considerable item.

We, therefore, have the greatest confidence in inviting the attention of railroad officials to the electrification of their mountain grades, for if the traffic is at all congested there, electrification is bound not only to improve the service, but to give a very substantial return on the investment. The electrification work that has already been done is enough to show that electric locomotives can handle any kind of service from the heaviest slow speed freight service to the fastest of heavy passenger work.

The next question is, when will the great lengths of line between the terminals, and connecting terminals and grades, be electrified? That is something that will depend entirely upon the territory through which the road passes and the population of the terminals. I regard it as entirely possible, if not highly probable, that within the next ten years one can travel from Boston to Washington by fast trains over the New York, New Haven & Hartford and the Pennsylvania Railroads, behind electric locomotives. The New Haven is now operating all trains between New York and Stamford by electricity and is rapidly extending its electrfication to New Haven. It is also working at the Boston end of the line between Boston and Providence, besides having its Harlem River division and its immense freight classification yards operated exclusively by electricity.

The Pennsylvania has the vast network of lines on Long Island, besides the New York terminal, operated by electricity. It is now working on the Philadelphia terminal which must be electrified in order to increase its capacity. The bad tunnel at Baltimore must be electrified and the terminal at Washington must soon follow. With these city terminals all electrified, it is a foregone conclusion that the whole distance from New York to Washington will be equipped, as it would be impractical to have any breaks in the service; aside from this consideration, however, I believe that the population is so large as to make it a paying investment anyway.

Similar results will follow in other sections of the country, but more slowly and only as it is found by the railroads to pay a good return on the investment. That is the only thing that will make general electrification possible. No matter how desirable it would be to the public the railroads cannot electrify until it can be made to pay, either at present rates for freight and passenger service or by the undesirable alternative of higher rates for the improved service.

Just a word to people who are for compelling the railroads to electrify their terminals in large cities. Don't do it. The railroads in this country are fully alive to the advantages of the electrification for such situations; or if not now, they soon will be, for they are all studying the subject with the greatest care. I believe the matter can be safely left in their hands for a few years, at least, until the necessary plans can be made and all the innumerable details connected with the adoption of the new motive power are fully worked out. Without this careful consideration, the plans will be only half baked, and vast sums of money will be wasted and the full advantages of electrification will not be secured. When the railways of any city decide to electrify the terminals, they should work out a harmonious plan that will include all of them, so that power may be furnished from a common power house, and all equipment be interchangeable.

Electrification is bound to come on a large part of the railroads sooner or later in any case, but the steam railways should not be forced into it until they have had ample time to mature their plans.

There are many, many advantages from it, some of which are only beginning to be understood and some of which have never had the correct value. When all have been shown by experience to have certain definite values, and the best way to secure the advantages has been thoroughly worked out, the railroads will need no compulsion.

Following the foregoing paper, Mr. Storer presented a number of lantern slides showing various types of electric locomotives and discussed their salient features. Prominent among the list were the locomotives of the New York, New Haven & Hartford, the Pennsylvania, the St. Clair tunnel, the Boston & Maine and several European types. In general, the types were shown to exhibit the various forms of connections between the motors and the driving wheels, and to show the disposition of the weight, and the arrangement of wheels as affecting the riding qualities of the locomotive. The different forms of transmission between motors and driving wheels were distributed as follows:

1st. Gearing motors directly to the axles as on the ordinary street car. Among the locomotives of this type shown was one experimental locomotive for the Pennsylvania Railroad, the St. Clair tunnel and the Spokane & Inland, all being suitable for service at speeds below 30 miles per hour.

Operating with this type of locomotive with heavy motors mounted directly on the axle, is confined to low speeds because of the effect upon the track on account of the dead weight on the axle and the low centre of gravity.

2nd. The locomotive having the motors mounted on a hollow shaft surrounding the axle; these hollow shafts or quills being connected to the wheels through the springs.

The early New Haven passenger locomotives were of this type and have been quite successful, although some trouble was experienced with them after a few months of operation, on account of nosing. This was overcome by the addition of pony wheels at each end of the locomotive and the use of a toothed cam centering device.

This type of locomotive is very successful as long as the track is kept in good surface, for, in spite of the low centre of gravity, the motors are entirely spring borne, so that a direct shock is very seldom given to the track.

3rd. The third type of locomotive exhibited had the motors geared to the quill surrounding the axle, which is connected to the driving wheels through long flexible springs which permit the motor and quill to move a total distance of three inches in a vertical direction with respect to the axle. It is, therefore, possible to mount the motors directly on the truck frame. This form of locomotive is made for the New York, New Haven & Hartford, with but one motor per axle and with twin motors. Where one large motor is used, it is necessary to have double gears which require very accurate alignment. Where twin motors are used only one gear is required and both of the motors drive through the same gear. The small motors are found to be less expensive for single phase work and are lighter and easier to handle. On the New Haven Railroad, the same motors are used for both locomotives and multiple unit cars, excepting, of course, the motor frames which have to be adapted for a different type of mounting. This type of locomotive gives high centre of gravity and is an exceptionally easy riding machine. All of the weight above the wheels and axles is spring borne, and there being absolutely no tendency for nosing, the machine

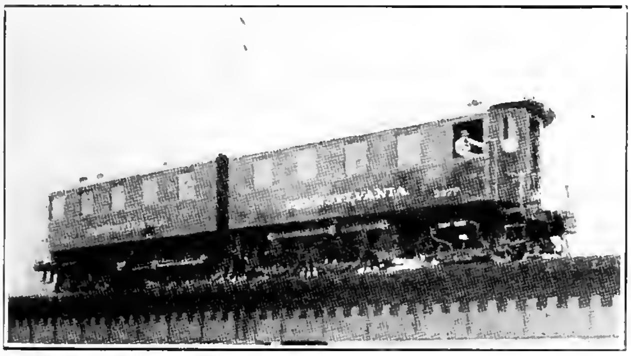

Fig. 2.—A Pennsylvania Railroad 160-ton D.C. Locomotive (600 Volts) for New York City Pennsylvania Terminal Operation.

is very easy on the track and is very comfortable to ride in.

Locomotives for both heavy freight and passenger work and for switching service with this type of drive were shown. It has been adopted as a standard by the New York, New Haven & Hartford, which has purchased over sixty locomotives of this type.

4th. Locomotives with motors mounted high in the cab and connected to the driving wheels through parallel rods from the motor to a jack shaft on the same level as the driving axles and thence to the drive-wheels by other parallel rods. The principal locomotive of this type which has been built is that of the Pennsylvania for use in the New York terminal. This is probably the most powerful electric locomotive ever built. It is used to haul trains of more than 800 tons weight up a 2 per cent. grade into the station. The locomotive weighs about 160 tons and has exerted a drawbar pull on level track of nearly 80,000 pounds. It is also able to handle the heavy passenger trains at 60 miles per hour on level track. This type of locomotive has the highest centre of gravity of any that have been built, and its operation on the track is similar to that of the best steam locomotives. A few years ago this would not have been considered very good by electrical engineers, but sad experience with machines having low centre of gravity has modified their opinions to a great extent and they are now glad to claim that such locomotives are as good as the best steam locomotives. This locomotive has established a wonderful record for reliability, there being only thirteen train minutes delay charged against the locomotives in the first year's operation. Such a record with 33 locomotives is little short of marvelous.

Another type of locomotive exhibited was that of the Italian States Railways, which connects the motors to the driving axles through a Scotch yoke. This is a form of side rod which is quite satisfactory for slow and moderate speed service. It has never been used for high speeds.

Another type is a combination of gears and side rods. This form is used for the locomotive built by the Oerlikon Company, in Switzerland, for the Loetchberg tunnel. The motors are geared to a jack shaft, instead of connecting to the latter by means of parallel rods as in the case of the Pennsylvania locomotives. This permits the use of a much higher speed motor and a considerable reduction in the weight and cost of the locomotive. It also enables the use of a single design of motor for various speeds of locomotives which may be secured by simply changing the gear reduction.

Some of the principal advantages of electric locomotives were discussed briefly and Mr. Storer expressed himself as being opposed to the extremely high wheel loads which are being used with the latest types of steam locomotives, and advocated the use of electric locomotives with wheel loads about equal to the maximum wheel loads on freight or passenger cars. It is claimed by many engineers that the destruction to the track is due almost entirely to the locomotives. These heavy wheel loads are probably necessary for the tremendous units that are now demanded, but the use of electric locomotives will permit the weight to be distributed so that no locomotive wheel need carry more weight than a car wheel in the same train. This will give the best possible results on the roadbed and will give more flexibility in locomotive units.

The matter of the arrangement of the commission appointed by the Department of Marine and Fisheries to investigate the water levels on the St. Lawrence River at and below Montreal, was brought up by Mr. Frank Carvell, at a recent session of the Commons, who stated that dredging had reduced the level in the harbor of Montreal very considerably from what it was eight or ten years ago. He suggested that the channel had something to do with the lowering of the water level in the harbor. The Honorable Mr. Hazen stated that the efforts of his department were now being directed to getting a thirty-five-foot channel. He had discussed the matter of the water level with officials of the department and had come to the conclusion that it was most desirable to obtain the best information on the point. On the recommendation of Messrs. Stewart and Forneret, of the department, he had invited Professor Haskell, dean of the Engineering School at Cornell University, to join them. Prof. Haskell had been engaged upon many river undertakings. The commission would confine its attention to the water levels between Montreal and Quebec, because the matter of navigation was urgent. A report was required without delay, whereas a commission with wider instructions would necessarily occupy a much longer period.

COSTS OF HAULING ASPHALTIC PAVING MATERIAL BY MOTOR TRUCKS AND TEAMS.

In his report on a proposed municipal asphalt plant for the District of Columbia, Mr. D. E. McComb submitted the following estimates on the cost of hauling asphaltic material in the District. The estimates are based on a haul over the streets of Washington. For hauling with a 5-ton motor truck, the following assumptions are made: Load = 6 dumps = 90 cu. ft. Cost per day, $12. Speed, 10 miles per hour = 1 mile in 6 min. Estimated time required to load, 9 mins.; unload, 7 mins.; tally, 2 mins.; total, 18 mins. For hauling with wagon and 2 horses the assumptions were: Load = 4 dumps = 60 cu. ft.; rate, $4.50 per day. Estimated time to load, 6 mins.; to unload, 6 mins.; to tally, 2 mins.; total, 14 mins. Estimated speed of team, 2½ miles per hour (1 mile in 24 mins.). The comparative cost per cubic foot of hauling asphaltic paving material for resurfacing and new work is estimated to be as follows:

	Motor truck. Per cu. ft.	Wagon. Per cu. ft.
½-mile haul	$0.0067	$0.0058
1 -mile haul	.0083	.0094
1½-mile haul	.0103	.0150
2 -mile haul	.0121	.0187
2½-mile haul	.0133	.0187
3 -mile haul	.0148	.0250
3½-mile haul	.0167	.0375
4 -mile haul	.0190	.0375
4½-mile haul	.0222	.....
5 -mile haul	.0222	.....

For hauling hot stuff on minor repair work the following estimates are given: Assumed haul by 1-horse cart for distances up to 2½ miles and by 3-ton auto trucks for distances beyond 2½ miles:

Cost of cart haul for average distance of 1¾ miles:

Estimated time required to—	Minutes.
Load	5
Unload	30
Tally	2
Total	37
To make trip and return	84
Grand total	121

Number of trips per day, 4.	Per cu. yd.
$2.50 ÷ 4 × 24 cu. ft.	$0.0260
Add 10 per cent. for delays	0.0026
Cost per cu ft.	$0.0286

Cost of 3-ton auto truck haul for average distance of 3 miles, 12 miles per hour:

Estimated time required to—	Minutes.
Load	7
Unload	45
Tally	2
Total	54
To make trip and return	30
Grand total	84

Number of trips per day, 6.	Per cu. ft.
$10 ÷ 6 × 45 cu. ft.	$0.0370
Add 10 per cent. for delays	.0037
Cost per cu. ft.	$0.0407

The estimate for hauling asphaltic paving material for patching work is based on the following assumption: One horse cart: Load = 24 cu. ft. = 3 dumps, 8 cu. ft. each; cost per day, $2.50; estimate of speed, 2½ miles per hour; average haul = 2½ miles.

Estimated time required to—	Minutes.
Load	5
Unload (averaged)	30
Tally	2
Total	37
To make trip and return	120
Grand total	157

	Per cu. ft.
Number of trips per day, 3; cost per cu. ft. = $2.50 (÷ 3 × 24)	$0.0347
Add 10 per cent. for delays	.0035
Total cost per cu. ft.	$0.0382

REFUSE DESTRUCTION AND STEAM RAISING.

The result of an official test of a duplicate front-feed refuse destructor at Nuneaton, which was first utilized for steam-raising purposes in April of last year, appears in the report for 1912 of Mr. F. C. Cook, borough engineer and surveyor of that town.

The contractors were Messrs. Heenan and Froude, Limited, of Manchester, and the cost of the furnace, apart from buildings, was $3,902.50.

The main results show that during the eight hours of the test the furnace dealt with 61.5 lb. of refuse per square foot of grate area per hour, which is equal to nearly 50 tons per day, and that the water evaporated per lb. of refuse consumed, from and at 212 deg. Fahr., was 1.727 lb.

Very little use was made of the spare coal-fired boiler after the completion of the duplicate destructor. Altogether, the destructors worked for 302 days, and dealt with 2,711 wagon loads and 4,654 cart loads of house refuse, together with 99 loads of trade refuse, equal to a total weight of about 6,382 tons, and representing about 88 per cent. of the total house refuse collected.

The gross cost of labor in destroying the refuse was 36c. per ton, against 42c. in 1911. In 1911 the net cost (excluding capital charges, and deducting the saving in coal) worked out at $1.18 per ton; but last year there was an actual saving of $621.25 during the time the destructor was at work, as compared with what the cost of raising steam by a coal-fired boiler would have been over the same period. The result was mainly accounted for by the enhanced price of fuel—viz., 80c. per ton against 55c.—and to the very great increase in the quantity of sewage pumped, which would have led to a corresponding increase in the weight of fuel used in generating steam.

The sum of over $146 was realized by the sale of tin and galvanized-iron scrap. This is very nearly all profit, as this waste material was previously burned in the tips.

CONTENTS OF THIS ISSUE.

GOVERNMENT SUPERVISION OF DAM CONSTRUCTION.

During the recent flood disasters in the United States at least one dam was reported as having given way, and there were many cases of panics and excitement in numerous towns over reports of the collapse of others. To what extent such panics and fears are justifiable we do not know, but there have been instances in the past in the United States of careless dam construction, disastrous to human life, which partly justifies a distrust by the people of such engineering structures. It all reflects to a certain extent on general engineering, and should be prevented. We have government supervision of buildings, etc., for the safety of the people. Why not —and more so—have it for the design and construction of dams if they endanger in their failure human habitations and life? An instance of what such supervision could have prevented was the Austin dam failure, which many of our readers will remember took place in the United States in 1911. Investigation after the accident brought out the facts that a portion of the dam which drawings showed thirty feet thick at the base was only twenty feet thick; that the existence of a cut-off wall or key, which was supposed to be four feet thick and extend four feet into bed-rock across the whole upstream face of dam could not be found.

Incompetent engineering in the above case and panics in the recent flood disasters in the United States should lead governments to adopt means of exercising skilled engineering supervision over dam construction. Ordinary static stresses in dam design are easy enough to figure, but the foundations and joints bring in elements of doubt that require to be met by liberal factors of safety in design. There should be absolutely disinterested inspection to see that improper economical risks are not taken for the sake of financial questions involved.

Such accidents and panics reflecting on the profession are not desirable, and engineers should be the first to applaud competent engineering and government supervision that would make impossible mistakes which endanger human life. Such a course serves the twofold purpose of increasing the people's confidence in their safety and preventing possible disasters which reflect on the ability and honor of the whole engineering profession. It would still further safeguard engineers in as far as when pressed for reasons of economy to lower factors of safety in design they would know it was impossible, due to government inspection.

UTILIZING THE SUN'S RAYS FOR POWER PURPOSES.

Most engineers have listened with interest at some time or other to tales of the practicability of gathering and utilizing the heat and intensity of the sun's rays in tropical countries for power purposes. Recalling the ancients and fairy tales of wonderful sun-glasses that were going to burn up ships and wreak destruction on those who ventured to oppose them, further memories come of years that have passed, with innumerable engineers longing at times to make a servant of the intense tropical heat of old "King Sol." We dwell on the fruitlessness of it all; probably recall that, while scientists in laboratories in a small way have successfully experimented, yet no practical results have ever followed, and, consequently, we are inclined to dismiss the possibilities of the scheme as hopeless.

While no startling success has yet been met with in the way of converting the energy of the sun's rays into useful work, yet it is well to remember that every perfecting of low-pressure steam engines brings the possibilities of that goal nearer. There have been advances in that line of late years, and it is of consequent interest to hear of a company which started construction in 1812 in Egypt of a 100 horse-power pumping plant to be operated by boilers obtaining fuel from the sun's rays. The history of the plant as given lately in London, England, by an official of the company is that on completion of the plant and after three days' successful running the specially designed zinc boilers, which acted satisfactorily in the United States, were unable at Cairo to stand the heat. They leaked, and had to be discarded, and the plant was at a standstill pending the delivery of cast-iron boilers ¼ inch thick. He hoped these would be fitted and the plant start running afresh on June 1st next. They had selected cast-iron boilers in order to obtain quicker delivery. In future they would use dished steel-plate boilers, for the manufacture of which it would be necessary to procure beforehand the required sets of dies. The first cost naturally was a heavy one, being probably twice that of a steam plant of equal capacity. As to operating, it might be stated that when coal was at the price of $2.50 per ton, the sun-power plant could compete with it; when coal cost more, then the sun-power plant made a profit. Starting the plant at 6 a.m., they had steam at 6.15. Starting at noon, with cold water, they had steam in three minutes. The low-pressure engine used was a special type of engine, a d Prof. C. V. Boys, their consulting engineer, while feeling satisfied the boilers would substantiate in practice what had been advanced in regard to them, believed it was on the utilization of their steam that they were bound to concentrate their attention.

The report does not sound encouraging, but when we consider what the successful operation of such principles of design would mean to Egypt and other tropical countries in the way of irrigation and pumping possibilities, we cannot help wishing the enterprise all kinds of success.

Wireless and other modern inventions help one to believe that modern ingenuity will in some way find means to economically capture and convert into more useful energy the sun's heat of the tropics.

THE PACIFIC HIGHWAY.

The agitation and propaganda for good roads carried on by Highway Associations throughout the Dominion have invariably had for their primary and chief argument (and an immediately pressing argument) the mutual benefit to be derived by settlers and farmers and nearby residents in cities and towns through increased and easier trade facilities. Increased land values for farms, due to increased accessibility, have had prominence, and the importance of automobile and pleasure trips has been secondary—and rightly so—in all highway promotion. The exception to the above that might be said to prove the rule, is the case of "The Pacific Highway" in the Rocky Mountains. The proposed route of this highway is from Hazelton, in Northern British Columbia, to Yuma, Arizona, and ultimately on to Mexico. The British Columbia and California legislatures are in favor of the scheme, Washington is inclined to be favorable, and, provided the Oregon and Washington legislatures signify their willingness, the building of a splendid international highway, three thousand miles long extending from Hazelton southwards will soon be a certainty. In the meantime it is partly under construction in many parts already.

Considering the physical difficulties and expense of road building in the mountains, the slight population along great parts of the route, the certainty that fertile spots will only be found intermittently and that the major portion of the road must always run through uncultivatable mountain region, one might expect difficulties and discouragement in persuading legislatures to vote money for such a task. It is in the fact that the association which is stimulating constructions on the Pacific Highway bases in great part its arguments for the prompt construction of same on benefits to be derived from tourist travel that it differs from most highway organization. The vice-president of the association, Mr. Todd, in a recent address in British Columbia dwelt strongly on these benefits. Tourists from North America spent in Europe annually more than thirty times the amount of the expenditure of the Provincial Government for last year. Motorists from America and from England went regularly to Europe for motoring trips, and the amount which was thus spent out of the country—which might be spent in it—could be easily ascertained as an enormous sum. The Pacific Highway would tempt all these and many foreigners more to tour on the Pacific slope. In Mr. Todd's opinion 1916 will see not less than ten thousand foreign motor cars touring on British Columbia roads, and that these will do the Province a thousand times more good than any damage they may incidentally do the roads. Every one of these tourists will be a possible investor, and, presuming that these ten thousand cars average four passengers apiece and stay an average of thirty days at an expenditure of $10 a day for each person, $15,000,000 are at once in sight as a revenue which tourists must pay here for bare necessities.

Those who have ever been through the mountain districts of Europe or spent any time in the Canadian Rockies realize and will agree with him in what a tremendous asset British Columbia's scenery is, once they have accommodation and means to make travel in the remoter parts comfortable. The British Columbia legislature for years has spent more annually on trails and road-making than any other province in the Dominion. The work has been well done, and it has been rather a heart-breaking and long fight, contesting with nature as seen in British Columbia.

The people and province will reap the benefit in the end, and the present support of the Pacific Highway is only another laurel in British Columbia's crown for energetic and unswerving progress towards better means of communication throughout the Province.

The mail and passenger steamer "Lintrose," which has been constructed to the order of the Reid Newfoundland Company, of St. John's, Newfoundland, by Swan, Hunter & Wigham Richardson, Limited, at Newcastle-on-Tyne, has successfully completed her trial trips, and is on the point of sailing for St. John's to take up her service of carrying passengers and mails between Newfoundland and the mainland.

The steamer is exceptionally strongly constructed for running through the ice which she will frequently find on her route, and is very finely modelled. She has accommodation for 180 first-class and 150 second-class passengers.

ALKALI-RESISTING CONCRETE.

Tests which have been carried on by the engineers of the United States Reclamation Service to develop a modified cement that would resist the action of alkalis and be cheaper than the commercial Portland cement is in the west were recently embodied in a paper read before the International Association for Testing Materials, and reads as follows:—

Sand Cement.—A good cement, comparing favorably in strength with the Portland cement used in its manufacture, can be made by regrinding Portland cement with certain proportions of inert materials (such as rock or sand, granite, basalt, sandstone, and tufa), the mixture being ground to a greater fineness than that of the original cement. The amount of diluting material may range from 30 to 50 per cent., depending on the fineness of grinding practiced.

In connection with the materials used in these tests, special interest has of late attached to the use of puzzolanic materials such as tufas, in which a portion of the silica is considered to be in "soluble" form such that it will enter into chemical combination with the uncombined lime in the Portland cement with which it is ground. That such materials can be used to good advantage in making a cement of this class has been proved by their successful use for this purpose in the construction of the new waterworks system for the city of Los Angeles in California. They are also of interest as being of possible assistance in the solution of the alkali problem. They are, however, of a lower specific gravity than most of the other materials (such as quartz sands, granites, etc.) which are generally available for making a cement of this class; and in the writer's opinion it has not yet been proved that they should be chosen in preference to these latter materials when both are available, as, on account of their lighter weight, they would tend to produce a cement of a lower strength than these heavier and harder materials.

As a result of the above investigations the use of cements of this general class has been adopted for two large masonry dams, and for the auxiliary works in connection with a large earthen dam whose construction work is about to be commenced by the Service. Grinding mills will be erected and the sand-cement manufactured at the sites of these structures, using Portland cement purchased in the usual manner, and the field materials available at these points.

With regard to the general use of cements of this class, it is evident that they are not applicable for use on small structures in scattered locations, on account of the cost of erection and operation of the grinding plant required. In the case, however, of a single structure requiring a large amount of cement, and located at a point where the cost of Portland cement is high, it would appear that they can be safely used, provided proper care is exercised in the selection of materials and in the process of manufacture, with a considerable saving in the cost of the structure as a result.

Disintegration of Concrete by Alkali Action.—Among the problems met by the engineers of the Reclamation Service, as well as by other engineers in the arid regions of the Western States, is that of the destruction of concrete by alkali action under certain conditions and in certain localities.

These arid regions contain numerous deposits of so-called "alkali," and in many places the ground waters are strongly impregnated with these salts in solution. This general term "alkali" is used to include a variety of substances, of which the salts of sodium and potassium are among the most common, although salts of calcium and magnesium are also included in the general term. As the use of cement and concrete in these regions is a comparatively recent move, any effect that this alkaline water might have on concrete structures with which it comes into contact has until recently been a matter of conjecture if it has been considered at all.

Investigation of the subject, in the form of analysis of samples representing the alkali deposits and the ground waters where disintegration has occurred, shows that the sulphates, and especially sodium and magnesium sulphates, either singly or together, are the principal salts acting to cause this disintegration. The chemical action involved seems to be analogous to a considerable extent to the destructive action of sea water on concrete, in which magnesium sulphate is considered to be the principal salt acting to cause disintegration.

The conditions most favorable to attack appear to be where the concrete in small structures, such as culverts, etc., is subject to the action of seepage water coming through from the soil at the back, or of water which has become highly saturated and concentrated owing to light and sluggish flow in the water-courses in which the structures stand. Conditions of alternate exposure to water and air as produced by a varying flow in these water-courses are also especially favorable to the development of this action. It is hardly necessary to add that the character of the concrete also has a marked effect on the extent to which the destructive action will take place, a dense, well-made grade of concrete being, of course, more impervious and less readily attacked than concrete of a less dense, porous nature.

On a recent visit by the writer to one of the projects of the Service, where alkali conditions are prevalent, a marked contrast was noted between a tunnel lining on this project, which was in excellent condition, and another on private work in the same vicinity, which had been badly attacked by alkali action, and where the concrete work was evidently of an inferior quality. It is also probable that the character of the materials used for concrete aggregates, as well as the workmanship, may have some influence in the matter.

To refer briefly to the best method of remedying the difficulty, the main point is the production of a dense and impervious concrete, such that seepage of the alkaline waters through the concrete will be prevented. As to whether this can be best brought about by the use of a specially prepared rich and dense mixture without any other form of treatment, or whether some form of waterproofing treatment will be the best solution, is a question now under investigation.

TELEPHONES FOR FIRE PROTECTION.

According to the British Columbia report of the provincial forest branch it is their intention to construct telephone lines and pack trails where they are most needed throughout the province as a protecion from forest fires. Over the greater part of British Columbia neither of these essentials is at hand. As a means of rapid communication, the telephone is obviously the most desirable, considered from the standpoint of usefulness and cost of construction and maintenance. For woods work, a single wire (ground circuit) strung on trees has proven very satisfactory, and may be constructed at a remarkably low figure considering the protection afforded. In the national forests of the Western States such lines have been built at a cost per mile varying from $30 to $80, depending on the accessibility of the country through which they run. Branching from trunk lines as mentioned above, there may be built cheap, temporary lines to "lookout points." A system of telephone lines is a tremendous aid in the prevention of forest fires, but should be accompanied by a system of good roads.

DESIGN OF AN AMMONIA-COMPRESSION REFRIGERATING MACHINE.

Assuming average temperatures of 70 deg. and 0 deg. F. for the ammonia in the condenser and evaporator, and allowing for losses at the regulating valve, influx of heat into the pipe connections and cold parts, and by superheating in the compressor, 450 B.t.u. per lb. of ammonia circulated may be taken as available refrigerating effect. Taking one ton of refrigeration as 322,000 B.t.u. (In the United States 288,000 B.t.u. is the recognized figure, based on a ton of 2,000 lb. and 144 B.t.u. per lb. of ice melted) per day of 24 hours, then $322{,}000 \div (450 \times 24 \times 60) = 0.497$ = pounds of ammonia to be circulated per minute per ton. Taking the volume of 1 lb. of ammonia vapor at 0 deg. F. to be 9.1 cu. ft., volume of ammonia vapor to be circulated per min. $= 0.497 \times 9.1 = 4.53$ cu. ft. = compressor displacement per min. per ton of refrigeration per day. This displacement is for machines of 2 tons of daily ice-making capacity; for machines of from 5 to 100 tons capacity the displacement ranges from 4.4 down to 4.1.

The maximum piston speed, because of the fact that self-acting mushroom valves are used, is about 350 ft. per min. The length of stroke of the piston should be from 2 to 2.4 times the diameter of the cylinder.

The cylinder walls, of cast iron, should be from 1 to 1⅛ in. thick to insure good working with ammonia at the pressures generally employed. With very close-grained iron, the thickness may be as little as ⅞ in. Liners may be used to advantage in cylinders over 8 in. in diameter. These should be not less than 1⅛ in. thick, and in 21-in. cylinders may well be 1½ in. thick to provide for stiffness, as they are supported only at the ends. The pores of compressor castings may be rusted up by subjecting them to a solution of sal ammoniac under a pressure of 200 lb. per sq. in.

The diameter of the suction valve may be made a little above, and the delivery valve a little below, one-third the diameter of the compressor cylinder. The piston rod should be made of steel having a tensile strength of from 78,000 to 90,000 lb. per sq. in., and an elongation of at least 21% over 6 in. The diameter of the rod should be one-quarter the diameter of the cylinder.

The mean effective pressure for an ammonia compressor working under conditions suited for ice-making may be taken as 60 lb. per sq. in.; from this the probable I.H.P. of the compressor may be computed, and that of the engine driving it will be about 25% greater. Also, I.H.P. of engine $= (2 \times$ ice-making capacity of machine in tons per 24 hours$) + 10$. For machines of less than 10 tons daily capacity, add 7 instead of 10.

Assuming the condensing water inlet temperature not to exceed 65 deg. F., then, for each ton of ice-melting capacity (ton of refrigeration) 60 to 70 running feet of 1¼-in. internal diameter pipe will be ample for submerged condenser pipe, and 90 ft. for pipes exposed to the air. The grids of coils for atmospheric condensers may be spaced 12 to 20 in. apart, 12 to 20 ft. long, and 8 to 12 ft. high.

Supposing that the brine is being cooled under conditions similar to those which exist when ice is being made, then for each ton of ice-melting capacity allow 125 to 150 running feet of 1¼-in. internal diameter pipe, it being understood that the greatest possible care is taken to insure an efficient circulation of the brine.—Condensed from a paper read by J. Wemyss Anderson before the Institute of Mechanical Engineers, November 22, 1912.

ARRANGEMENTS OF ROOFS FOR ENGINEERING WORKS.

A paper recently read by Mr. H. N. Allott, M.Inst.C.E., before the Manchester Association of Engineers, dealt with the construction and methods of roofing of engineering works as follows:—

Saw-tooth roofing, where possible, is usually arranged with the glazing facing north so as to prevent the direct glare of the sun through the glass. The principal advantage of the saw-tooth roof is that by its use a more evenly lighted and cooler shop is obtained. The amount of glazing to be allowed for in a roof of the ridge type should be not less than about 50 per cent. of the area of covering, and in districts with an atmosphere like that of Manchester this may be increased with advantage to 60 per cent or 70 per cent. The glass should be equally distributed on both sides of the roof, as by that means a more even illumination is obtained than when all the glass is placed on one side of the roof. Another advantage of distributing the glazing is that the direct glare of the sun and consequent heating of the shops in summer is minimized.

The roof covering in this country usually consists either of slates, asphalt felt, or corrugated iron. For slates or corrugated iron the roof generally is given a rise of not less than a quarter of the span, for if made of a flatter slope rain and snow are liable to blow in at the joints. For felted roofs the roof may be practically flat if the joints are properly made with mastic, and it is only necessary to give a fall of one or two inches to the foot to allow for drainage. Galvanized corrugated iron is usually only used in this country for buildings required for temporary purposes, and when used should be carefully painted before and after fixing, and afterwards properly maintained, as otherwise its life is only short. Slating, when used, may be laid on battens nailed to spars, or to boarding nailed to the purlins. When laid on spars the slates should be pointed on the underside with hair mortar. When laid on boarding the boarding should be covered underneath the slates with sarking felt.

An alternative to natural slates are asbestos slates, formed of a mixture of asbestos and cement, several reliable makes of which are now on the market. These are made about 16 in. square, and are best laid either with the diagonal parallel to the slope of the roof, or in what is termed "honeycomb" fashion. The point of the slate should be cut off, as it is otherwise liable to be broken by anyone walking on the roof. It is necessary in all cases to see that proper lap is given to the slates, and this is especially the case where asbestos slating is used, as owing to its smooth surface the roof is more liable to leakage, where proper attention is not given to this.

An alternative to galvanized corrugated iron sheeting has also recently been supplied by corrugated sheets of asbestos composition, which can be obtained up to 10 ft. in length and 27½ in. in width.

In the author's opinion, asphalt felt laid on thicknessed, grooved, and tongued boarding forms the best covering for engineering shops and similar buildings. Besides being cheaper than slating, it is not damaged like slating by men walking on the roof to attend to skylights, and for similar purposes. The use of felt of good quality is permitted by the building departments of most local authorities, although one or two treat it as not being sufficiently incombustible. The felt is laid in mastic and nailed to the boarding, the joints being lapped about 4 in. One thickness of stout felt will make a satisfactory job, if properly laid and if proper

attention is given to maintenance, though the roof is generally covered with an extra thickness of a thinner quality of felt where a thoroughly good job is required. One advantage of the use of felt is that a considerable saving can be effected by forming the gutters in felt, instead of using cast-iron gutters; this is especially the case in roofs where large valley gutters are required. A considerable amount of lead, required for flashing at various parts of the roof, can also be saved. The only attention required to be given to felted roofs is a coat of varnish at intervals of about five years.

The comparative costs of the before-mentioned types of roof coverings are as given below, per square yard of area covered:—

20 B.W.G. galvanized corrugated sheeting	$ .79
Asbestos corrugated sheets	1.28
Slates laid on spars	1.15
Slates laid on match-boarded on underside	1.52
Slates laid on 1¼-in. boarding, including sarking felt	1.58
Asbestos slates cost about 12 cents per square yard less than natural slates.	
Asphalt felt, one layer, thick quality, laid on 1¼-in. boarding	.97
Asphalt felt, one layer thick, one layer thin quality, laid on 1¼-in. boarding	1.22

The roof glazing is best carried out with patent glazing, of which there are several satisfactory makes on the market, the alternatives to patent glazing being wood or T steel glazing bars, the glass being puttied in. The patent glazing is preferable, as with puttied bars the putty becomes defective and the glazing leaky, unless systematic attention and painting is given. The best systems of patent glazing consist of a steel bar, to which is fixed a lead flashing, which is worked down on to the glass to form a weather-tight joint. In most cases the glazing bar is sheathed all over in a lead casing, the ends of which are soldered up, thus obviating the necessity of painting. The bars should be galvanized before the sheathing is put on. Except in the case of vertical or steep-pitched glazing, as in the case of a saw-tooth roof, it is not advisable to joggle the glazing bar to form a lap in the glass. If this is done on a flat-pitched roof leakage is liable to occur, owing to capillary attraction between the two panes of glass. Where it is necessary to form a joint in the glazing on a roof of ordinary pitch, it is better to step the glazing bars. The roof glazing is best carried out with wire-wove glass, which holds together and does not drop if a pane is broken.

PANAMA PACIFIC EXPOSITION.

The Pacific Gas and Electric Company has been awarded a contract for the supply of gas, electricity and steam for the time and period of the Panama-Pacific International Exposition Company. The contract is as follows: "Contract signed between Panama-Pacific International Exposition Company and Pacific Gas and Electric Company, under which the latter will supply exclusively during the next 3½ years all electric current required for power and lighting purposes during the term of the World's Fair in San Francisco in 1915, and during the period of construction and dismantling. Present estimates are that the Exposition will require 20,000 horse-power. Gross amount of this business estimated at $500,000. Simultaneously contracts also made with Pacific Gas and Electric Company, for all gas and steam required by Exposition."

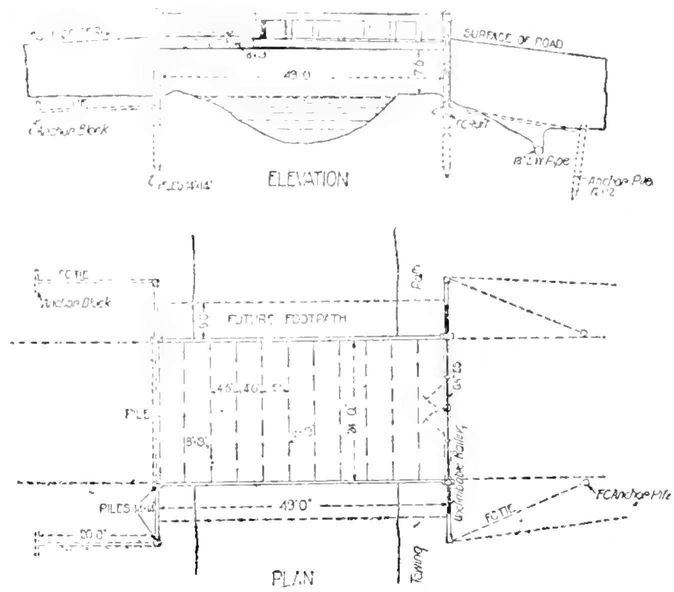
REINFORCED CONCRETE BRIDGE.

A description of a small reinforced concrete bridge with special features of design is given by Mr. D. M. Jenkins, Assoc. M. Inst. C.E., of Neath, England, in an issue of Ferro-Concrete. The following is an abstract from same.

The bridge has a span of 49 ft., a width between parapets of 24 ft., and a clear headway of 7 ft. 6 in. above the towing path of the canal.

No solid foundation being available at a moderate depth, the drawings provided for ten ferro-concrete piles, 14 in. by 14 in., which were made on the spot, to be extended upward as columns for the abutments and wings, the wing piles being tied to anchor piles, 12 in. by 12 in., by ferro-concrete ties. The accompanying drawings make clear the structural features of the bridge.

The contract length of the piles was 23 ft., which was based upon the indications of a trial shaft sunk in the marsh about 15 ft. distant from the site of the north abutment, strong gravel having been found at a depth corresponding to a length of pile of 20 ft., and provision made for entering 3 ft. into the gravel. Above this formation the whole of the excavation for the shaft was in a rather soft alluvial clay.



Reinforced Design.

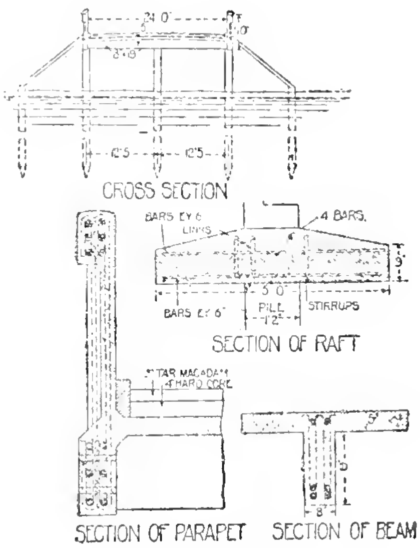
Pile-driving was commenced on the south bank of the canal, and good results were obtained, the final set, measured for ten blows of a 2-ton monkey with a drop of 3 ft., being ⅜ in. to ¾ in. On the north bank, however, no satisfactory set was forthcoming down to and at the contract depths—nothing better in fact than from 3 in. to 6 in. for ten blows. It was then decided to drive an experimental pitch pine pile, 40 ft. long by 14 in. square, on the line of the abutment and near the central pile, but no better result was obtained. The absence thus indicated of the stratum of gravel found in the trial shaft, although it had clearly been reached below the south bank, farther away from the shaft, pointed to a deep "wash-out" of that deposit within very narrow limits; and in view of the uncertainty as to the extent of lengthening of the piles required to reach the solid, the desirability of adopting some alternative plan was considered.

Eventually it was decided, in consultation with Messrs. L. G. Mouchel and Partners, not to lengthen the piles, but to rely upon them as they were to carry a load of 10 tons each and to carry the abutment and wings on a ferro-con-

crete raft, 5 ft. wide, and from 9 in. to 14 in. thick, which was designed to take the remainder of the total load. The raft was formed in situ on the puddled bank of the canal, which is known to have been constructed over 100 years back, and is thoroughly consolidated and sound. The calculated maximum load on the bottom is 0.8 per ton square foot, and the estimate formed of the safe load which the bank could carry has been fully borne out by the result of the test applied (which is described later), and the subsequent traffic over the bridge.

The abutments and wings are built up of ferro-concrete columns, curtain beams and curtains, thoroughly braced together and to the ferro-concrete raft, the wings being formed with a slight batter and finished off with a rectangular coping, also of ferro-concrete.

The superstructure consists of two pilastered main beams, which form the parapets; cross beams, spaced 4 ft. 6 in. apart; and a continuous decking, 5 in. thick, with cambered upper surface—all moulded in situ so as to form a monolithic whole. Holes are left in the parapets, two to each bay, to enable ferro-concrete brackets to be bolted on to carry future footpaths.



Reinforced Design.

The roadway is formed of a hard core, 4 in. thick, of local sandstone, broken to 2½-in. gauge, and a surface coat of tar-macadam, 3 in. thick, a blue brick channel being laid on each side to carry off surface water. At the north end of the bridge self-adjusting unclimable iron railing and a pair of iron gates are fixed, the gate pillars being bolted down to the decking, and the standards of the railings similarly secured and attached to the ferro-concrete piers by means of ¾ in. diameter bolts passing through them and enclosed in lengths of galvanized iron tubing.

The approach road on the south side is carried on an embankment, with 1 to 1 batters, covered with sods obtained from the marsh; and on the north side, after the preliminary filling to counteract the outward thrust of the abutment during the process of testing, the surface was brought up to the required level by the tipping of town refuse, and a temporary sleeper road formed. Part of the "Back Cut" of the canal has been enclosed by 18-in. stoneware socket pipes, bedded on and surrounded with cement concrete, and the toes of the embankment are supported by retaining walls of rubble masonry.

In his article Mr. Jenkins points out that there were two special conditions governing the design of the bridge: (1) The superstructure had to be kept up so as to give a clear headway of 7 ft. 6 in. in accordance with the requirements of the Neath Canal Navigation, who have statutory powers, and whose consent had to be obtained in the first place for the crossing of the canal; and (2) the surface level had to be kept as low as possible so as to avoid excessive gradients on the approaches. To meet these opposite conditions, the arrangement was adopted of two main girders, carried up as parapets with cross beams spaced sufficiently close together to keep their depth within the required limits. Further, for a number of years only limited cart traffic will be required to pass over the bridge, but later on, when the marsh land has been developed, access for the general public will have to be provided. To meet this condition the bridge has been formed to the by-law width of carriageway —namely, 24 ft.—and provision made, as before mentioned, for adding when required a footpath to be carried on cantilevers outside each parapet. This is an economical arrangement, while at the same time it admitted of the distance between the road surface and the underside of the main beam being kept to a minimum—the alternative having been to space the main girders 36 ft. apart to increase their depth and strength, and incidentally the gradients of the approaches, and to incur practically the whole cost of the finished bridge long before it was necessary.

MOTOR FUELS AND THEIR FUTURE PRICE.

Mr. G. S. Sayner, in a recent lecture to the members of the Harrogate and District Automobile Club, pointed out that benzol was one of the first products of the distillation of coal tar, and was obtained in very large quantities on the Continent, and to a limited extent (now increasing largely) from the recovery plants fitted to ovens in which metallurgical coke was produced. This hydrocarbon had the formula C_6H_6, and was only a little less volatile than petrol, 1 lb. giving 4.5 cubic feet of vapor at normal temperature and pressure. Like all the volatile hydrocarbons, there was a certain amount of variation in the determinations of its calorific value—from 18,188 B.th.u., according to Thompson, to 17,780 as determined by the bomb calorimeter. The commercial washed or rectified 90 per cent. benzol was the only kind really suitable for motors, though Mr. Sayner said he had run a car on the crude 60 per cent. unwashed. There was no difficulty in driving motor carriages of any description with 90 per cent. benzol as the principal fuel. With regard to napthalene, coming from various products of the distillation of coal, it contained 93.7 per cent. of carbon, and required melting or vaporizing, and special apparatus for obtaining the explosive mixture. One advantage was its low cost—0.32d. per horse-power-hour in a recent test. Mr. Sayner added: "In looking into the future I see great possibilities for napthalene, as the source (coar tar) from which it is obtained is more likely to be equal to the demand. Those in the North of England especially are in a favored position, as the tar of the coal is full of napthalene. The quantity required for motor purposes could be easily provided."

CANADIAN PULP AND PAPER MANUFACTURERS.

The Canadian Pulp and Paper Manufacturers' Association has been formed for the "object of gathering statistics on the possibility of the world's market, the collection of rainfall data, and to co-operate with the Dominion Government in the establishing of laboratories for forest products."

EXPLOSIVES.

By J. K. Moore.

(Continued from page 534, last issue).

After the hole is loaded, or nearly so, put in your fuse and see that the powder in the fuse is exposed and dry. After placing the fuse in the powder, put in some more powder to insure ignition and tamp in the usual way, using wood or copper rammer. If the hole is deep, use double fuse, place the end in a cartridge of powder and see that it is tightly tied on.

Powder does not require a detonator or cap. It ignites from a spark. Powder will not explode if wet.

When a shot has to be set off at cross-roads, or where the traffic is heavy, men should be sent out along the different roads to stop the traffic. They should have a flag and signals should be arranged so that the powderman could be warned when everything is clear. Even with this precaution the usual calls of alarm should be given.

Electricity and Wire Fuses.—When using electricity, or a battery and wire fuse, in setting off shots, never connect up the wires to the power wires or battery until every one has gone to a safe place as there may be a leakage and a premature shot follow. Platinum electric fuses can be procured almost anywhere for black powder, and combination fuse and detonator for dynamite. Be very careful that you get the very best and be sure you keep them dry.

I am convinced that in quarry work and heavy blasting, wire fuses, cable and battery, is the safest method of exploding powder or dynamite, because immediately you disconnect the wires of the cable from the battery there is no danger from fire in the drill hole, as there would be from ordinary fuse, even in case of misfire. If you have a misfire you can go over your wires immediately after without danger. Wire fuses are placed in the charges the same as other fuse and the same care exercised when tamping so as not to cut the wire. In making your connections, see that the ends of the copper wires are clean and bare, raise every connection thus made from the ground by placing a dry piece of wood or stone under, as the damp soil may ground the current, and be sure you do not allow two connections to touch or else you will cause a short circuit.

Mis-shots.—Mis-shots are shots that have failed to explode. The causes are manifold. It may be faulty fuse, poor detonators, carelessness in pulling the fuse out from the cap or charge. Or in electricity, it may be from overcharging your battery, that is, having more shots connected up than your battery can stand. It may be the platinum in the cap, broken wires, grounding or short circuit. But whatever the cause, care should always be exercised in returning to the shot if ordinary fuse is used. Several hours should always elapse between the time of lighting and returning in such cases, as there may be smouldering, and catch the powder in the fuses again. In electric fuses, it may be better to allow a few minutes, but be sure you disconnect the battery. If you cannot find the cause and have to put down another primer or fuse in the drill hole, be very careful not to remove all the tamping, and, in the case of dynamite, it is a dangerous practice at best. In black powder, use a copper picker used for the purpose, and be sure you moisten the tamping.

It is also dangerous to drill a new hole near the misfired one, that is, within two feet, hoping that it may explode the other one, when it (the second shot) explodes, as the shock from the drilling may set it off prematurely.

Taking Out Charge.—Always follow the safest way, and that is, drill a new hole several feet away from the one that has misfired, never closer than three feet, drilling down to about the level of the charge in the other. Then load lightly and fire. Then you will be able to get a new primer down to the misfired charge in the other.

In partly exploded shots, do not try to drill the hole out to make room for another charge. Simply put in some more explosive, another primer, with no tamping, and set off. Care must be used not to put in too much dynamite to spoil the hole for further use.

There are three or four practical ways to break boulders. The first is by drilling a small hole called a plug and putting in the necessary charge. But this is slow, if it is simply to remove the boulder. The second way is by bull-dosing. This is done by placing several sticks of dynamite on top of the boulder on the flattest part near the centre, and covering with fine moist clay to exclude the air. But this is very expensive as to powder. The third way is to dig a hole with a bar under the boulder, and always try to get the charge under the concave part near the centre and never on the round or bulge side. This is the cheapest and best method.

Hardpan.—In blasting hardpan drill holes horizontally into the bank about eight to ten feet apart and six to seven feet deep, with bars or spoon shovel for the purpose. These holes can be sprung by a high explosive to make room for the charge, about one stick of 60 per cent. dynamite is sufficient for the first time. This gives you an idea how it will work and what powder you may require to get a pot-hole sufficiently large enough to receive the full charge. Be careful not to reload before all chance of fire from the fuse has gone and in springing use no tamping, as confining the charge will break the wall of the bore hole. After springing and before placing the final charge, clean the hole well out, removing all loose material with the spoon shovel. Then load according to what you want done. This has been found a very successful way.

Holes can be widened in hardpan in the following way: Drive your bar-drill to above twelve to fifteen inches into the bank, then use a primer, of about one-third or half a stick of 40 per cent. dynamite, according to solidity of material, clean out and repeat, driving the bar or drill twelve inches further and charging again, and so on. Six feet is about the distance most successfully done in this manner, and the hole is anything from three to five inches wide.

This method suits best where two men are working, but in case of a whole crew with horses, etc., causes the others to lose more time than anything gained. However, a good foreman can easily regulate this. Do not use a high explosive for the final charge, as it is too quick, and therefore local. It is better to use black powder, which is slower in action, or Judson powder of low grade. Judson powder is highly recommended for that particular, because it is almost as slow as black powder and has double the power.

Blasting Stumps.—In blasting stumps, take your bar and spoon shovel and drill a hole under the stump and close to the main root. If the stump is large, you may have to spring the hole to make room for the charge. After charging, tamp well. In wet ground be careful about greasing your primer and see that you use waterproof fuse. Water makes good tamping for dynamite, but not for black powder, excluding the air, but you must see that it comes up to the surface level at the stump. If the stumps are in very soft ground, it will be deemed advisable to place a flat rock

under the stump to place the charge on. If the earth is free from rocks, the hole may be drilled with an earth auger. If large stumps show signs of rottenness in the centre, place your charge under the most solid part, and in cases where they burst open, leaving parts of the stump and roots still in the ground, which have afterwards to be dug out, try a heavy chain fixed tightly round the upper part of the stump, about twelve inches or so from the ground. This is sometimes very successful, but depends on the powderman and the judging of his shots.

Mixing Powders.—Never use two qualities of powder in the same drill hole or charge, as it does not seem to be any great benefit. Dynamite will set off black powder, but it is so quick in its action that it may do considerable damage before the total ignition of the black powder takes place, making fractures, which allow the gases of the latter to escape, thus reducing its power. However, it is very effective in cases where a number of holes have to be tried, to load one with dynamite and the other with gunpowder or Judson powder, and so on, and firing with battery.

The magneto machine is one of the best, and be sure you get it strong enough to set off as many shots at one time as you require.

The cable used to connect up the wire fuses and the magneto machine should be strong, well insulated and pliable. A reel should be used for winding it up immediately after use.

Explosives will keep a considerable time if well stored, but one should be careful not to order more than he expects to use during the season. Explosives should not be mixed in a magazine nor should caps or detonators be stored with powder.

In handling dynamite do not throw it violently from your shoulder, nor smash the box open with an axe or hammer, or in any other violent way, particularly if the weather is hot; nor should it be packed too high one on another, in the magazine. In hot weather do not carry a box of dynamite on your head or shoulder, over rough ground, in case of stumbling. Black powder in kegs is loose, and weighs twenty-five or fifty pounds in boxes, compressed in cartridges. Do not smash a keg or box open with any iron or steel tool; wood or copper should only be used.

Magazine.—A magazine should be built much the same as a root house, frost proof, if possible, good drainage, well back from any settlement or highway or heavy timber, and according to the Explosive Regulations of this Province, chapter 80, paragraph 4, all the ironwork in the inside should be covered, or nails driven down below the surface of the boards and puttied. The hinges should be copper, also the lock and key. The floor should not be rough or rocky; it should be of earth, but better still, wood free from any iron or steel. Brick, concrete or stone is dangerous. Bitumen is one of the best. A lightning conductor should be put on outside and be well grounded away from the magazine.

TEMISKAMING AND NORTHERN ONTARIO RAILWAY.

We publish below statistics of the operation of the T. & N. O. Railway, which is managed through a commission appointed by the Ontario Government. There is a slight decrease in the total revenue for 1912, and a slight increase in the corresponding year's expenditures. The reduction in revenue from operation is due mainly to the Cobalt mining camps' increased use of mills for concentration of their ore values and a consequent great reduction in tonnage of ore shipped out. The use of electric energy for power purposes is also reducing to a great extent the transport of coal to the north country.

FROM 1905 TO 1912, INCLUSIVE.

Temiskaming and Northern Ontario Railway Statement.

Summary.

Freight revenue	$4,727,351.90
Passenger revenue	3,461,112.10
Other revenue	877,352.72
	$9,065,816.81
Earnings—Ore Royalties, etc.	473,643.74
Balance at profit and loss.....	$ 338,286.03

Maintenance of ways and structures	$1,612,665.27
Maintenance of equipment	924,744.46
Transportation expenses	3,359,455.75
Traffic expenses	72,376.52
General expenses	393,687.36
Total expenditure	$6,362,929.36
Paid treasurer of Ontario.........	2,838,245.16

COFFERDAM CONSTRUCTION.

In a paper published by the American Society of Civil Engineers, Volume XXXIX., entitled, "Fremantle Graving Dock: Steel Dam Construction for North Wall," J. F. Ramsbotham describes the construction of a cofferdam in Australia for a submerged depth of over 50 feet. If, after excavation, a doubtful foundation was disclosed the site for the graving dock was to be changed and a quay wall built. The following is an abstract from the paper:

Steel sheet piling was used and the material in which the piles were driven consisted of a hard limestone cap, coral, clay, and sandstone, the limestone cap being particularly hard in a portion of the pumping station, where a total of 60 ft. of driving had to be done, or, in other words, each pile had to be driven 60 ft. into the ground. It is worthy of record that, in driving one of the steel piles, a 45-lbs.per-yd. steel rail was cut into two pieces, one section being found subsequently on excavating within the dam.

From a driving point of view, these piles are admirable, as the cross-sectional area, or displacement, is small compared with the covering area of the face of the pile. Although whippy, with care very few piles were damaged; and, further in shipping 1,900 piles, 60 ft. long, from the United States to Western Australia, not one was damaged, and only two were damaged in handling for driving. In handling from the steamer it was found best to have 8 x 3½-in. fish-plates of Oregon pine, 10 ft. long, with a sling chain around them, placed 20 ft. from one end. In handling, preparatory to driving, a single piece of 7 x 3-in. Oregon pine, 8 ft. long, was found best, and was slung one-third from one end.

Design of Dam.—The points that require careful watching in designing a dam are: (1) Strength of skin (which can be taken as a beam supported at several points, and to an extent this is advantageous, as benefit is derived from contraflexure); (2) strength of walings or longitudinal beams; (3) strength of shores or transverse columns; and (4) factor of safety on the dam.

Great benefit may be derived from working in water, as it is possible to calculate exactly the loads which the various members of the structure have to carry; and, needless to say, the object is to place the walings and shores so that they and also the skin will have an ample factor of safety.

In designing the dam, a maximum tide of 6 ft. 6 ins. above low-water mark was considered, and the dredged bottom was taken at 49 ft. below low-water mark, thus giving a total calculated head of 55 ft. 6 ins., which in actual work could be taken at 51 ft. Further, clay puddle was tipped to a minimum height of 9 ft. at the skin of the dam, in order to make a seal of the porous rock, and at the same time, reduce considerably the head on the dam. Assuming that the shores are placed at 10-ft. centres horizontally, the pressure on a strip of dam, 10 ft. wide is:

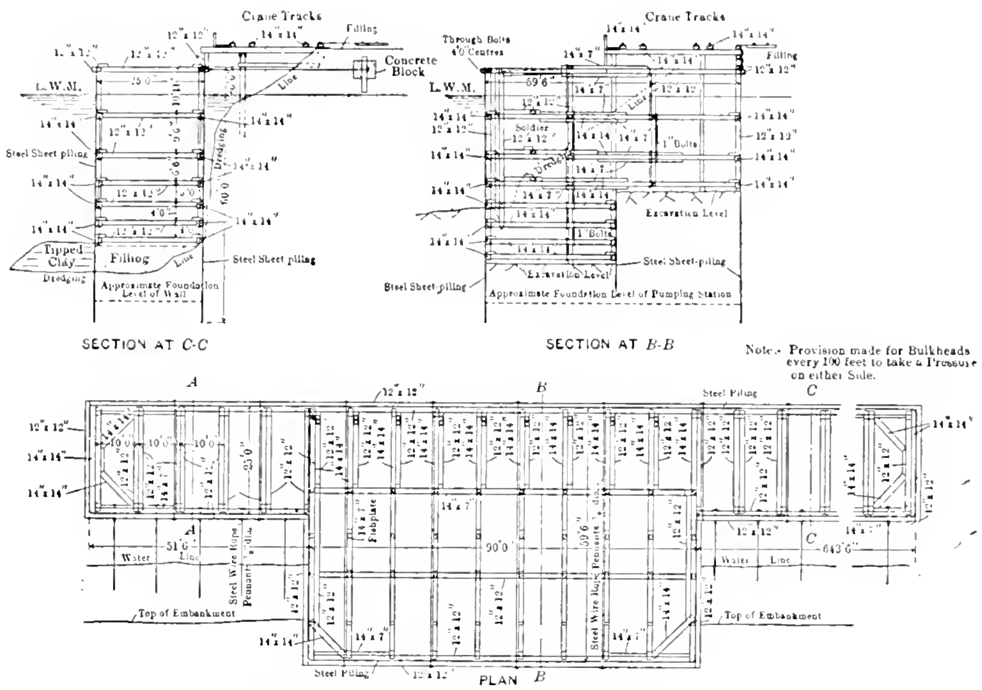
$$\frac{55 \text{ ft. } 6 \text{ ins.} \times 10 \times 55 \text{ ft. } 6 \text{ ins.} \times 64}{2 \times 2{,}240} = 440 \text{ tons}$$

The strength of a jarrah beam, loaded uniformly and supported at each end, is given by the following formula, in which K is a constant which has been ascertained to be 13; B is the breadth, and is assumed to be 14 ins.; D is the depth, and is assumed to be 14 ins.; and L is the length which is 9 ft., or 108 ins.:

Breaking weight, in hundredweights =

$$\frac{8\,K\,B\,D^2}{L} = \frac{8 \times 13 \times 14 \times 14 \times 14}{108} = 2{,}642 \text{ cwt.} = 132 \text{ tons.}$$

Thus, using a factor of safety of 3, the safe load $= \dfrac{132}{3}$ = 44 tons. From this the number of walings or beams required is $\dfrac{440}{44} = 10$.



Plan and Section of Cofferdam.

It is worthy of note that, in calculating the strength of walings, no allowance was made for the fact that the beams were continuous over several supports, thus giving a greater margin of safety than is shown. The shores or columns were 12 ins. square and 22 ft. 8 ins. long, and were worked out by Gordon's formula in a similar manner, one end being considered rounded and the other fixed, the factor of safety being slightly less than 3.

When the driving of the piles was completed, it was found that it was impracticable to keep them absolutely vertical or in line, due to the hard nature of the ground; and, although the divers packed between all piles and the back of the walings, a certain amount of unquestionable bridging or arching took place. This was so marked that, without any further delay, additional shores were placed alongside those already in, the factor of safety of the walings thus being increased to 3¾ and the shores to almost 4½.

The skin of the dam is important, and the largest span was settled empirically from observations and was a clear span of 8 ft. 8 ins., subjected to an actual head of 17 ft. 7

ins. of water. In the dam in question, the span was 8 ft. 7 ins. between the second and third shores. Between the first and second shores the clear span is 9 ft. 11 ins., and, although allowance was made for a high tide of 6 ft. 6 ins., it is seldom if ever reached. From the writer's experience, a clear span of 8 ft. 8 ins., subjected to a mean head of 10 ft. 8 ins., is quite satisfactory, the total load on a pile being 4.88 tons, and the maximum stress about 10 tons per sq. in.

Practical Construction Details.—First, it is of the utmost importance that the female end of the pile should always be driven over the male, and not the male in the female. If the latter is done, a column of spoil will be compressed under the male in the jaws of the female which will finally end in the bursting of the structure. To enable rapid progress two piles were split down the centre and a double male pile manufactured, riveting a 6 x 3 x ½-in. **T**-iron on the back for stiffness. By this means two piling machines were utilized; one was built on an outrigger, with one end supported on staging and the other end on a log on the ground, the piling frame, winch, boiler, etc., being self-contained and easily moved. The other machine was on a barge, and was also self-contained.

In passing, it may be mentioned that the piling winches were made by the Lidgerwood Manufacturing Company, and were capable of working a 2-ton "tup" or hammer. A 30-cwt. tup was found to be best in practice, and a good man can get 20 blows per minute, a 5-ft. drop being quite sufficient. From the plan it will be noticed that provisions were made for subdividing the dam every 100 ft. by using **T**-piles, a male and female **T**-pile being left opposite each other; this was done in accordance with the catalogue of the makers of the piling. When the time came to drive, however, difficulties arose, and as they could be overcome very easily by the manufacturers of the piles, the writer mentions them, hoping that he may thus assist others.

First.—By having a female **T**-pile, it would mean, in the ordinary course, driving a male pile in it; as previously mentioned, if this is done, it will end in disaster, unless the spoil in which it is driven is a fluid mud. To overcome this, a double female pile was made, and on one side a strip of iron, 1 in. wide and ½ in. thick, was tapped on the outside on one jaw in order to make a lock. The jaws were then interlocked, and the pile was driven, there being clearance for any displacement of spoil between the jaws.

Second.—Great care must be exercised in keeping the two **T**-piles parallel, otherwise obvious difficulties will arise in closing. The manufacturers could overcome this by making an expanding pile with slotted holes, so as to enable the closing pile to vary its width from the top to the bottom.

Third.—Even with parallel piles, it is extremely hard to marry in with the closing pile, and it is desirable to have a few piles of different width.

Fourth.—If a male **T**-pile is used at each side of the dam, as should be done, a double female pile is required with which to end, and such should be supplied by the manufacturers.

Fifth.—If a male **T**-pile is urgently required, it can easily be made, and at small cost, by riveting an ordinary 45-lb. rail to an ordinary pile.

Sixth.—In driving the piles, the moment one seems to be hardening up and has not reached the required depth, another should be driven ahead of it, and, if necessary, this should be repeated until there are signs of having reached soft ground again. It is then possible to exert more force, but even then abuse must not be resorted to, as there is grave danger of parting the piles, but if this does happen by having driven ahead, that danger is limited in extent and is only local.

From the cross-section it will be noted that the piles toward the shore were driven on the side of a cliff, which had been left in a very irregular condition by the dredging, and added considerably to the difficulties of the piling gang; it also rather retarded the progress, as some piles had to be drawn. A fair month's work for the two machines, there being two 8-hour shifts on each machine, averaged 370 piles, representing 9,361 lin. ft. of driving.

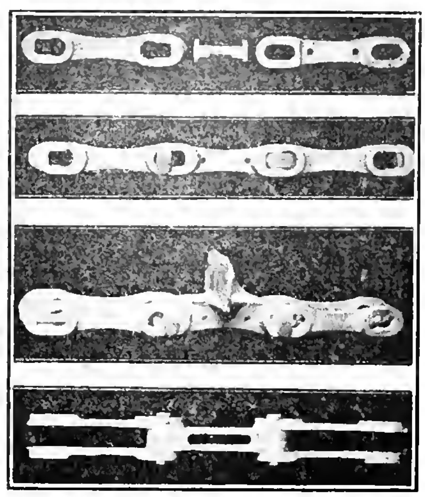
The first steel pile was driven on July 14, and pumping was started in Dam Section No. 1 on November 16, the entire dam being framed by the end of the year.

It is interesting to note that 1,872 steel piles were used, representing 47,385 lin. ft., or 9 miles of actual driving. In the first dam section there were 401 piles, which gives 24,060 lin. ft. of joint, representing very nearly 5 miles of joint.

A RIVETLESS CHAIN.

A chain was recently patented by Joseph L. Lee, general superintendent of the Cross Engineering Company, Carbondale, Pennsylvania, and manufacturing and selling arrangements have been entered into with the company, which is preparing to market the chain at an early date. The principle of this chain is entirely new, but simple, from which it derives its trade name of "Simplex." The accompanying illustrations of links, pins, attachments, and assembled parts are to a large extent self-explanatory, but the following claims are made for this new product by the inventor and manufacturers:—

This chain is interchangeable in all parts. Its parts are easily and quickly detachable, and each section can be so detached in less than a minute. The links can be released or removed by a horizontal movement of the diameter of the pin, or in the 9-in. pitch, 1⅛-in. movement, doing away with the necessity of adjustment of take-up when links or pins require renewal, or to reverse the pins for further service. It will operate over either a sprocket wheel or a traction wheel by reason of the concave shape of the links, and is also interchangeable with certain other types of rivetless chain. The chain has a wearing surface on both link and pin equivalent to standard riveted eye-bar chain, generally known as the 'Scranton' type of chain, the pins being reversible, so that after becoming worn on one side they can be reversed 180°, so presenting the unworn side for 100% additional service, and at the same time nearly restoring the chain to its original pitch.



A special feature of this chain, as well as a distinct advantage over any other type of chain, is the "lip" shown on the outside links. When the chain is in working position, and whether in the position of passing over a sprocket or

traction wheel, the double-slot space back of the pins on the centre links, forming a recess or pocket, is entirely closed. This prevents dirt or gritty material from coming in contact with the wearing surfaces, and if desired the recess or pocket may be filled with any solid lubricant, such as graphite or hard grease, and so insure the longest possible life to both link and pin at the contact points of wear and friction.

The links, being solid, have a distinct advantage over the web, or open, type of link, as there is no compression at any point on either link or pin to cause the chain parts or attachments to stick or to be disconnected with difficulty, and it is not necessary to remove the attachments to disconnect the links or pins.

The two centre links form a pocket for the insertion of the several forms of attachments required, and may be reversed "back to back" and so used for attachments requiring side elevation or conveyance. Attachments for this chain will first be made of malleable iron to meet standard elevating and conveying requirements, and for extraordinary service certain attachments will later be made of a special tough steel. Attachments when bolted to links will, it is claimed, bear an equivalent strain as if cast in one piece. The links are to be drop-forged from 30 to 40-point carbon steel and broached to assemble to accurate pitch, and the pins are also to be drop-forged and machine-finished, and to be shop-assembled to links to insure the free working of chain parts.

It is the claim of the manufacturer that this chain will in a large measure displace several of the types of riveted chain now in use. The Cross Engineering Company is preparing to manufacture this chain in 4-in., 6-in. and 9-in. pitch, and it is stated that the chain will be sold at no general increase in price over the standard type of drop-forged, riveted bar chain. It is the general claim that Simplex rivetless chain is more simple to assemble and disconnect than any other type of rivetless chain now in use, and that it is as easily detached as the Ewart type of detachable chain or belting.

SHORT METHOD OF COMPUTING AREA OF CIRCULAR SEGMENT.

By J. A. Macdonald.

To find the area of a circular segment: Find the area of the sector that has the same arc as the segment; find also the area of the triangle, whose vortex is the centre, and whose base is the chord of the segment; there the area of the segment is the difference or sum of these two areas, according as the segment is less or greater than a semicircle.

The chord and height of a segment are = 24 and 6; find its area.

$$\tan \tfrac{1}{4} n = \frac{2h}{c} = \frac{12}{24} = .5 = \tan 26^\circ\ 33'\ 54'' \text{ and hence}$$

$$n = 106^\circ\ 15'\ 36'' = 106^\circ.26.$$

$$2r - h = \frac{c^2}{4h} = \frac{144}{6} = 24, \text{ and } r = 15.$$

Then sector $= .008727\ n\, r^2 = .008727 \times 106.26 \times 225 = 208.64$;

also, triangle $= \tfrac{1}{2}\, c P = \tfrac{1}{2} \times 24 \times 9 = 108$;

hence, segment = sector — triangle = 208.64 — 108 = 100.64.

This is the usual method of obtaining these quantities. It involves the computation of the radius, the central angle, the area of the sector, and the corresponding triangle, and the difference between the sector and the triangle equals the area of the segment.

Trautwine gives a table of areas of segments, but, when the chord and mid-ordinate alone are known, as is frequently the case, the use of this table consumes considerable time. The diameter must first of all be obtained by the formula:—

$$D = \frac{s^2}{4r} + r,$$

in which D is the diameter, s the chord, and r the mid-ordinate. The mid ordinate must then be divided by the diameter. The table gives for this ratio a factor which must be multiplied by the square of the diameter to obtain the area of the segment.

In the handbook of the "Verein Hutte" there is a table of lengths of arcs, mid-ordinates, chord lengths and areas of segments for circles of unit radius corresponding to any central angle. In order to use this table it is, therefore, necessary to compute the radius and the central angle from the chord.

For facility of computation two tables have been prepared, one for areas of segments and the other for lengths of arcs. In one column the ratio of the mid-ordinate to the chord is given, and in the adjacent column the corresponding value of c. To obtain the area of the segment, the product of the mid ordinate and the chord is to be multiplied by c, obtained from the table. More time is saved by the use of the table of areas of segments, and this table is, therefore, given.

Areas of segments of circles:—

Span or chord = s.
Rise or mid-ordinate = r.
Area = c r s.

r/s.	c.	r/s.	c.	r/s.	c.
0.01	0.6667	0.18	0.6836	0.35	0.7280
.02	.6669	.19	.6855	.36	.7313
.03	.6671	.20	.6875	.37	.7347
.04	.6675	.21	.6896	.38	.7382
.05	.6680	.22	.6918	.39	.7418
.06	.6686	.23	.6941	.40	.7455
.07	.6693	.24	.6965	.41	.7493
.08	.6701	.25	.6989	.42	.7531
.09	.6710	.26	.7014	.43	.7569
.10	.6720	.27	.7040	.44	.7608
.11	.6731	.28	.7067	.45	.7648
.12	.6743	.29	.7095	.46	.7688
.13	.6756	.30	.7124	.47	.7729
.14	.6770	.31	.7154	.48	.7770
.15	.6785	.32	.7185	.49	.7812
.16	.6801	.33	.7216	.50	.7854
.17	.6818	.34	.7248		

As an illustration of its use the area of the segment being a chord of 3.9634 feet and a mid-ordinate of 1.5 ft. is computed.

s = 3.9634 ft.	r = 1.5 ft.
r/s = 0.3785	log. = 9.578023
r = 1.5	log. = 0.176091
s = 3.9634	log. = 0.598068
c = 0.7377	log. = 9.867880
Area = 4.386 sq. ft.	log. = 0.642039

The Canadian Contracting and Construction Company have opened offices at the McKinnon Building, Toronto, and at Brandon, Manitoba. The managing director is C. G. Gillespie, of Toronto.

COMPARISONS OF COST OF WOOD AND STEEL FENCE POSTS FOR RAILWAYS.*

Wood Posts.—The life of wood posts of various kinds actually in use is as follows:—

Life of Posts.

	Years.
Red Cedar	7 to 25
Cedar	10 to 30
White Cedar	12 to 17
Chestnut	10 to 15
Locust	7 to 20
Yellow Locust	15 to 30
Black Locust	10 to 25
White Oak	7 to 15

Doubtless some give little heed to the particular species of the timber that they use, and assume that any species of that genius has about the same life. This is manifestly incorrect as is demonstrated by the oak family. The inferior grades of oak have a life only of from 2 to 4 years, while a good white oak has a life in our northern climates of from 10 to 12 years at least. Certain classes of oak last much longer in their native regions than in other localities to which they are transported for use. This principle applies with equal force to every other class of timber.

In reviewing the replies of the various roads we find that the consensus of opinion, based upon experience of the users, is that the different classes of timber have an average life as indicated below:—

	Years.
Red Cedar	18
White Cedar	15
Chestnut	12
Yellow Locust	20
Black Locust	20
White Oak	10

Climatic influences have an important bearing upon this phase of the case, and may lengthen or shorten the life of a particular kind of wood, dependent upon locality in which used.

From information received, the cost of the various kinds of wood posts is:—

	Range.	Average.
Red Cedar	15c. to 25c.	22c.
Cedar	7c. to 20c.	14c.
White Cedar	12c. to 15c.	14c.
Chestnut	10c. to 27c.	20c.
Locust	15c. to 40c.	25c.
Yellow Locust	20c. to 38c.	30c.
Black Locust	15c. to 25c.	20c.
White Oak	11c. to 40c.	20c.

It was of interest to know to what extent wooden posts were subject to destruction by fire. Replies received indicated that this varied by from 1 per cent. to 5 per cent., with the exception of one road which reported a loss of 30 per cent. from this cause. We think it fair to assume that the average loss by fire is around 3 per cent.

Steel Posts.—Only two roads so far as we can learn make mention of having used any metal posts, and then but to a limited extent. In the one case bar iron ¼ x 2 inches was used and in the other old boiler tubes. We have reason to believe, however, that quite a number of roads, not replying to our circular, are trying out a proprietary metal post. Several styles of steel right-of-way fence posts are on the market. Their exploitation has just begun in the last year or two, and any statement as to their efficiency and economy could be but vague and from the manufacturers' standpoint alone. Greater experience may demonstrate their utility, but thus far we have no data upon them, and can only give some computations from one of the manufacturers, which might be of interest for study from the viewpoint of railroad economy. These figures, while prepared for a certain style of post only, if reliable, will no doubt be equally accurate for any other style of metal post, built along similar lines, and others are generally so designed.

Steel posts cost	23.03 cents
Cost of setting	1.30 cents
Total	24.33 cents
Estimated life	30 years

Based upon above figures, steel posts set one rod apart cost 81 cents per year.

The cost of setting wood posts is estimated at 5.8 cents each. The following table is based on wood posts costing from nothing up to 20 cents each, and is intended to show what the life of wood posts must be at different first costs to be as cheap as the steel posts:—

Cost of post. Cents.	Cost of setting. Cents.	Total cost. Cents.	Years it must last to be as cheap as steel. Years.
0	5.8	5.8	7.1
5	5.8	10.8	13.3
8	5.8	13.8	17.
10	5.8	15.8	19.5
12	5.8	17.8	21.9
15	5.8	20.8	25.6
17	5.8	22.8	28.1
18.53	5.8	24.33	30.
20	5.8	25.8	31.8

The above figures would indicate that wood posts costing 15 cents would have to have a life of 25.6 years and those costing 20 cents a life of 31.8 years to be as cheap as steel.

The first steel posts are said to have been manufactured about 15 years ago at Bloomfield, Ind. Others, doubtless, of different design unknown to the committee were manufactured as long ago and perhaps longer, but only during the past twelve years have they been given any serious study with a view to placing them on the market for ordinary right-of-way fencing. Hundreds were taken up and examined to discover signs of rust and deterioration at ground line or elsewhere. They have been in use at Spencer, Worthington, Bloomfield, Ind., and elsewhere in all kinds of soil and under all conditions. The investigations have resulted in placing them on the market during the past year or so.

To be of economic worth for right-of-way protection, a fence post must possess the following qualities: Durability, practicability, efficiency and the price must be right. Inquiry develops that one man can set in a day from 15 to 35 wooden line posts. To be conservative, 30 posts per day per man is assumed as the unit of work. Estimating wages at $1.75 per day places the cost of setting a wood post at 5.8 cents. The cost of post is estimated at 12 cents, resulting in an entire outlay of 17.8 cents. Experience is to have demonstrated that three men can readily set from 390 to 640 steel posts per day, or 130 to 213 per man—130 posts per man is taken as the basis of calculation with wages at $1.75 per day. This places the cost for setting a steel post at 1.3 cents. Cost of steel post 23.03 cents, plus cost of setting 1.3 cents, resulting in entire outlay, 24.33 cents.

* Abstract of report of a committee of the American Railway Engineering Association.

Comparative Cost of Steel and Wood.

Entire cost of steel post, 24.33 cts., estimated life 30 years
Money worth 6 per cent.
Entire cost of wood post, 17.80 cts.; estimated life 12 years
Expenditure for steel posts ....24.33 cents
Expenditure for wood posts ....17.80 cents

Difference .... 6.26 cents

Compound interest on 6.26 cents for 12 years amounts to 13.06 cents. At the expiration of 12 years wood posts have failed and need renewal. 13.06 cents has been saved over cost of steel posts. This is equivalent to purchasing 8.8 years more protection with wood. In other words, 24.33 cents expended for steel gives 30 years of protection, while same amount expended for wood gives 12 years original life, plus 8.8 years' interest on investment, or 20.8 years, a balance in favor of steel of 9.2 years. Viewing the matter from another angle, assuming that posts are set one rod apart, track protection costs per year as follows:—

Steel Posts—

Per rod	$	.0081
Per mile		2.59
Per 100 miles		259.00

Wood Posts—

Per rod	$	.0117
Per mile		3.74
Per 100 miles		374.00

Balance in favor of steel posts of—

$ .0036 per rod per year.
1.15 per mile per year.
115.00 per 100 miles per year.

Other advantages claimed are no staples used; right-of-way may be burned over from time to time without injury to posts. No loss from accidental fires and no renewal on that account. Special end, corner and gate posts must be used in connection with the steel line posts. No means are provided for bracing them so as to use them as end or corner posts. There is not enough steel in them to stand the strain of stretching a heavy wire fence. The minimum amount of steel is used necessary to meet requirements of a right-of-way fence. The line and end posts are treated as distinct problems. In this they are not unlike posts made of other materials. The demands on the end and corner posts are entirely different from those on the line posts. The line post should possess a certain degree of flexibility, while end and corner posts must be absolutely rigid. The following is the comparative cost of steel and wood end and corner posts:—

Cost of end post $1.62
Cost of corner post 2.30

Assuming it fair to say that twice as many end posts will be needed as corner posts, it places the average of the stretching post at $1.84 each. If $1.84, the cost of the steel corner post, bears the same relation to the cost of a good wooden corner post that the price of the steel line post bears to the price of the wooden post, then the economy is demonstrated. In order to determine whether or not this relation maintains, we resort to the following equation:—

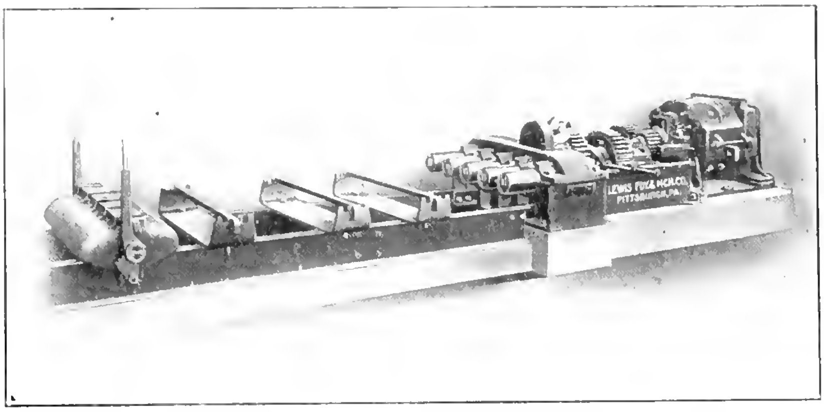
$$\frac{12c.\ \text{(cost of wood line post)}}{23.03c.\ \text{(cost of steel line post)}} = \frac{x\ \text{(cost of wood corner post)}}{\$1.84\ \text{(cost of steel corner post)}}$$

We find $x = 96$ cents, cost of wooden corner post, which appears to be a conservative estimate of the cost of a good wooden corner post. From a mathematical and perspective point of view, the manufacturer of the steel fence post appears to have made out a case that is worthy of continued and further close investigation. Time alone, under practical service conditions, can demonstrate if the figures are based upon substantial premises.

The steel fence post has not yet proved its merit in practice and at this time concrete with suitable reinforcement seems to offer the only solution to the problem.

MOTOR-OPERATED BAR-TWISTER.

In concrete work the steel bar gives the tensile and the concrete the compression strength. In order to produce a bar having a high elastic limit and homogeneous texture, it is essential that continuous and uniform running be attained on the machine used in twisting these steel sections. A great deal of trouble is experienced with belt-driven machines on account of belt slippage causing unnecessary strain during the twisting process, which usually results in an inferior product due to the elastic limit of the bar being exceeded. With a motor gear-connected to the machine, as shown in the accompanying illustration, an occurrence of this kind is practically impossible, since this method of motor connection insures constant torque being applied during the time the bars are being twisted.



The type of machine here shown, manufactured by Lewis Foundry and Machine Company, which is used for twisting Ransom bars, is arranged for two speeds. A 75-h.p. Westinghouse mill motor is used on five 1¼-inch bars, and a 60-h.p. motor on five 1⅛-inch bars. The twisting heads are steel castings arranged to receive tool steel dies for bars ⅜-inch to 1¼-inch, advancing by eighths of an inch. Bearings are brass bushed, and the shafts turned and hammered open-hearth steel. The bed is made of 10-inch channels of sufficient length to accommodate 60-foot bars. The tail-stock is so arranged that is may be locked on bed at any distance from head stock. An index is provided to register the number of turns made by the bar-twisting head. The dial is reset by hand, and can be moved back to zero when the load is released. The twisting speed of the head is about 60 r.p.m. for 1¼-inch bars, taking about one minute. The time consumed in loading and unloading is about two minutes; consequently, a complete cycle occurs every three minutes. One complete standard twist will occur on 1¼-inch bars in 12½ inches, and on 1-inch bars in 10 inches.

COAST TO COAST.

Vancouver, B.C.—Mr. H. M. Davy, engineer in charge of test borings for the public works department, Ottawa, has completed his work here of securing full data of Victoria and Vancouver harbors. Test borings were made along the south and north shores of Burrard Inlet with the object of locating sites for the proposed government wharves, and for other wharves and docks which may be erected here later on by the Dominion Government. Borings were made in False Creek in order to secure data for the amount of dredging which would be required, and to learn the class of materials which will have to be removed. The contract for this work has already been awarded to the Pacific Dredging Company, Limited. In Victoria a great many borings were made to secure information necessary for the proposed improvements to the inner harbor, and also for the proposed wharves for the outer harbor. The work in Victoria was frequently delayed by rough weather, but no delay was caused here, owing to the harbor being practically landlocked.

Montreal, Que.—An extensive programme of harbor improvements for the coming season, mapped out by the harbor commissioners, marks a new era in the history of the port of Montreal. The guard pier will be completed, and the south side described on the maps as the east wall quay embankment, will be continued to effect the backing up of the great volume of water below Victoria pier, across the channel in the direction of Moffat's Island, thus diminishing the velocity of the St. Lawrence current. The estimated cost of these improvements exceeds $2,000,000. A great portion of the material to be used in the erection of breakwaters, piers, etc., will be procured from the Mount Royal tunnel. Already great quantities of the solid rock are being shipped from back of the mountain to the water-front by the Canadian Northern Railway. Another improvement to be completed is the ballasting of the high level tracks which have been laid down from Victoria pier to the Racine pier. These will be trimmed and made permanent.

Victoria, B.C.—A deputation consisting of members of the Board of Trade and City Council will go to Ottawa to interview the Dominion Government upon the necessity of making immediate and adequate provision for the handling of large vessels at the outer wharf. In a recent letter to the City Council Mr. E. J. M. Nash, the special representative of the Royal Mail Steam Packet Company, which concern has four 20,000-ton vessels on order at Belfast to be ready to break into the service of this coast immediately the Panama Canal is completed, pointed out that the present facilities at Victoria, both as regards handling the traffic of such vessels, and as regards having them repaired in the event of an injury, were utterly inadequate; and that if Victoria desired to take her proper place as an ocean port it was up to her not only to extend her wharf accommodation in a greater ratio than has even been contemplated so far, but to at once make a start upon the construction of a large drydock.

Toronto, Ont.—A unique collection of model roadways in miniature is now on exhibition in the Parliament Buildings for the education of the general public in the secrets of highway construction in the province. Stretched upon a frame along with others dating from time immemorial and composed of bits of the stone and material of the actual construction, is a replica of the old Appian way as it came from the hands of the ancient Roman builders. There is also the model of an old French road constructed previous to the year 1775, following upon the Roman style of stone laying. It is composed of two layers, the foundation being formed of broad flat stones cleverly jointed by hand and the interstices filled with carefully ground pebbles. The next design in the evolution of the modern highway advocated the laying of the stones on the edges and in this way the wearing capacity was hugely increased and the drainage made more simple. The English Telford road followed, with a stone base laid entirely by hand and a curved surface. The old macadamized road which proved the most efficient of all for increasing road traffic is shown subject to the improvements which the highways department of Ontario has instituted in the substitution of three layers for one to withstand the wear and tear of heavy automobile driving. An exhibit of peculiar interest is that of a bituminous asphalt or tar highway comprising in all six layers of a most durable nature, and intended especially for pleasure drives where power machines are in constant use. This road the Ontario Government will experiment with to some extent during the year, and it is hoped will prove it so successful that actual construction will be undertaken. The display is under the care of Provincial Engineer of Highways W. A. McLean, and has been obtained from the public roads department of the United States Government.

Kingston, Ont.—The first step towards the cleaning up of the waterways of the province in accord with the recommendations of the recent convention of the International Waterways Commission has been taken, under the direction of the provincial board of health here. Owing to certain local conditions which are considered to be especially suited for experimentation by the board, F. A. Dallyn, provincial sanitary engineer, with a staff of assistants, has begun operations in the line of water investigation. A laboratory has been opened in Clarence Chambers and a launch has been chartered. Tests will be made from here down through the islands and for a space around the city. The investigation is made under the co-operative management of the Ontario and United States authorities, Dr. McLaughlin, an American expert, working jointly with F. A. Dallyn, provincial sanitary engineer. The working staff employed in that direction, it is understood, will be supplemented by a number of advanced science students now studying at Toronto University.

New Westminster, B.C.—In addition to the three million dollars which the Canadian Northern Railway will spend in improvements at Port Mann, an equal amount will be expended in New Westminster. According to recent despatches, Sir William Mackenzie and Col. Davidson, who are at present in London, are finding no difficulty in obtaining money for the project. Definite appropriations have been made for extending the railway through the city to the North Arm Bridge, and for the Port Mann improvements. This sum will be expended on elevated tracks, terminal yards on the Royal Mill site, trackage on the Trapp ranch and on the North Arm bridge, to connect with the Lulu Island line to Steveston. It is planned to start the Port Mann construction prior to the commencement of the local improvements, and it is stated that the contractors will have the work at the former place under way within a month. This work consists of filling in, the construction and equipment of machine and repair shops, boiler works, roundhouses and other terminal buildings. About twenty miles of storage and sorting tracks will be provided as a first unit.

Ottawa, Ont.—Mr. L. J. Burpee, secretary of the Canadian section of the International Waterways Commission, in a recent interview, said in regard to certain reports from Washington as to the abolition of the organization, they were evidently based on a misconception of the status of the international joint commission. "Neither Congress nor the

Imperial or Dominion Parliament," he said, "has any power to abolish the commission that constitutes that tribunal. Three were appointed by the President of the United States and three by the King on the recommendation of the Governor-in-Council of Canada—that is, practically on the recommendation of the Canadian Government. They were appointed under terms of the Waterways Treaty, which was signed in 1909 and ratified in 1910, and one of its provisions is that the treaty shall remain in force for five years from the exchange of ratifications and thereafter until terminated by twelve months' notice by one or other of the high contracting parties. The treaty, therefore, remains in force at least until the year 1916, and the commission, which is an essential development of the treaty, also remains in existence until that year at least. The personnel of the commission, the individual members, may, of course, be changed at any time by the National authorities by whom they were appointed; but the commission itself rests upon the foundation of a solemn treaty entered into by the two countries and cannot be put out of existence until the treaty itself comes to an end."

Toronto, Ont.—A deputation from the district between St. Thomas and Windsor, representing all the cities and the municipalities, waited on Hon. Adam Beck and the Hydro-Electric Commission at the Parliament Buildings recently and advocated the southern route as near to the lake as possible as the most advantageous one for the route of the proposed transmission line that is to convey between 25,000 and 30,000 horse-power to the various municipalities between these two points. It is proposed to build an electric railway along the right of way. Hon. Adam Beck explained that three or four routes had been suggested, and that the most advantageous one would be selected.

Ottawa, Ont.—In view of the new loan and subsidy, which the Canadian Northern interests are now busy negotiating, and which the government is proposing to grant, the question was asked by A. K. Maclean, of Halifax, as to what amounts have been paid since August 28, 1912, by the minister of finance and the receiver-general to the Canadian Northern Company from the proceeds of the authorized loans. In answer to the question it was stated that from the date mentioned until March 20, the Canadian Northern had received from the Dominion treasury $6,901,991.25 from the proceeds of loans authorized in connection with their line from Montreal to Port Arthur. The maximum amount payable is $35,000 per mile for 1,050 miles.

Winnipeg, Man.—The Canadian Domestic Engineering Company, Limited, announces the opening of a branch at Winnipeg, in the Alfred Building. The western manager is Frank W. Walker, M.E., of Winnipeg. Mr. Walker is a McGill graduate, and was formerly with Babcock & Wilcox Company, and more recently with the Transcona Shops.

PERSONAL.

DR. HARRIS LOGAN has been appointed medical health officer of Niagara Falls, Ont.

MR. ANGUS SMITH has resigned his position as city engineer of North Vancouver. His resignation will take effect at the end of April.

MR. HENRY JUNGERMAN, formerly with the Motive Power and Inspection Department of the Harriman Lines, has been appointed railway representative of the Tate-Jones & Company, Inc., of Pittsburg, Pa.

J. C. DUFRESNE, M.Can.Soc.C.E., M.Can.Mi.Inst., formerly of Penticton, B.C., is now associated with the consulting firm of Cummins & Agnew, Vernon, B.C. Cummins & Agnew make a specialty of municipal and irrigation work.

ARTHUR H. BLANCHARD, M.Can.Soc.C.E., professor of Highway Engineering in Columbia University, on March 31st delivered an illustrated lecture on "Highway Engineering in Europe and America," before the Brooklyn Institute of Arts and Sciences.

MR. JOHN A. BENSEL, M.Am.Soc.C.E., New York State Engineer, Albany, N.Y., on March 20th delivered an illustrated lecture on "Inter-relationship of Highways, Waterways and Railways" before the graduate students in Highway Engineering at Columbia University

JAMES COWIN, manager at Winnipeg for the C. A. P. Turner mushroom system of construction, has left Canada to take charge of Mr. Turner's affairs in Texas. A. W. Fosness and S. J. Sieverson, both of Mr. Turner's head office at Minneapolis, have taken charge of the Winnipeg office.

MR. H. R. PARSONS, C.E., graduate of the University of Michigan, has been appointed city engineer of Peterborough, Ont. Mr. Parsons was for six years employed as assistant city engineer of Ottawa, being in charge of the construction of pavements, sewers and waterworks systems in that city.

W. J. WELLER, provincial bridge builder for Manitoba, has been appointed superintendent of construction of bridges on the main line of the C.N.R. at the coast, and has left to commence operations. Mr. Weller has been with the G.T.P. for some time and for many years was connected with Mackenzie and Mann interests.

W. H. BREITHAUPT, C.E., is continuing the engineering office in which he was formerly associated with the late E. H. Keating. Chas. B. Kingsley, C.E., will be associated with Mr. Breithaupt. Mr. Breithaupt is a member of the Canadian Society of Civil Engineers, American Society of Civil Engineers and also of the Institute of Civil Engineers of Great Britain.

VIRGIL BOGUE arrived in Victoria, B.C., recently for a consultation with the minister of railways, Hon. Thos. Taylor, respecting work for which he is the consulting engineer in British Columbia. Mr. Bogue, whose headquarters are in San Francisco, recently reported upon the projected dock improvements for the Grand Trunk Pacific Railway Company at Prince Rupert. Recently the Canadian Pacific Railway Company engaged Mr. Bogue to report upon the projected Rogers' Pass tunnel, for the construction of which tenders are now being called.

OBITUARY.

ALBERT G. MACFARLANE, district engineer of the National Transcontinental Railway, dropped dead in his room at the Russell House on April 4. He was a native of Almonte, Ont., and had been at various periods in the employ of the Parry Sound, Midland, Algoma, and Canadian Northern Railways. He was 52 years old.

GEORGE P. BROPHY, C.E., superintending engineer of the Ottawa River works for 36 years, one of the founders of the Ottawa Electric Street Railway and Lighting Companies, and a figure in the local financial world, died at Ottawa on April 4th. He was 65 years of age. As superintending engineer Mr. Brophy was actively identified with important government projects all over the Dominion. Besides being a director of the Ottawa Electric Company and the Ottawa Electric Railway Company, the deceased held extensive interests in British Columbia and other provinces,

as well as locally. He assisted in forming the Ontario Graphite Company, the Dominion Carbide Company, Ahearn Electric Heating and Manufacturing Company, Locomotive and Machine Company of Montreal, the Thousand Islands Land Company, the Ontario Smelting, Milling and Refining Company, and other similar organizations. He was a director of the Ottawa Gas Company and a vice-president of the Ottawa Trust and Deposit Company.

SOCIETY MEETINGS.

A joint meeting of the Electrical and Mechanical Sections of the Canadian Society of Civil Engineers was held on Thursday, April 3rd, at 8.15 p.m. A paper on "Electrification of a Reversing Mill at the Algoma Steel Company," by B. T. McCormick, A.M.Can.Soc.C.E., was read by the author.

Dr. John W. S. McCullogh, chief health officer of Ontario, will deliver an address on Friday, April 11th, 1913, at 8 p.m. on "The Evolution of Public Health," at the Engineers' Club, Toronto. The library committee announces that a series of interesting lectures have been arranged for.

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, T. S. Young, 220 King Street W., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Mucklestone; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson, Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P O. Box 1290. Meets 2nd Thursday in each month at Club Rooms, 584 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose: Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O Box 7, St Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

The Canadian Engineer

An Engineering Weekly

THE GEORGIAN BAY—OTTAWA—MONTREAL WATERWAY

By J. A. MACDONALD

The Georgian Bay-Montreal Canal project is one of the most important the Federal Government of Canada has to face. At the time the surveys for it were being carried on it was a subject of considerable discussion, but of late on account of its political aspect parliamentarians and politicians have been more interested in it than engineers. Each year, the expansion of trade and increased railway traffic between east and west makes the canal more important. Mr. Macdonald, of the Topographical Surveys Department, Ottawa, briefly reviews the proposed course of canal and the difficulties encountered, gives figures and data, and discusses the question in a way which we believe will prove interesting even to those who, previously acquainted with the subject, have perhaps of late years grown hazy, and who will no doubt be glad to refresh their memory and consider things from the viewpoint of the author.—[Editor.]

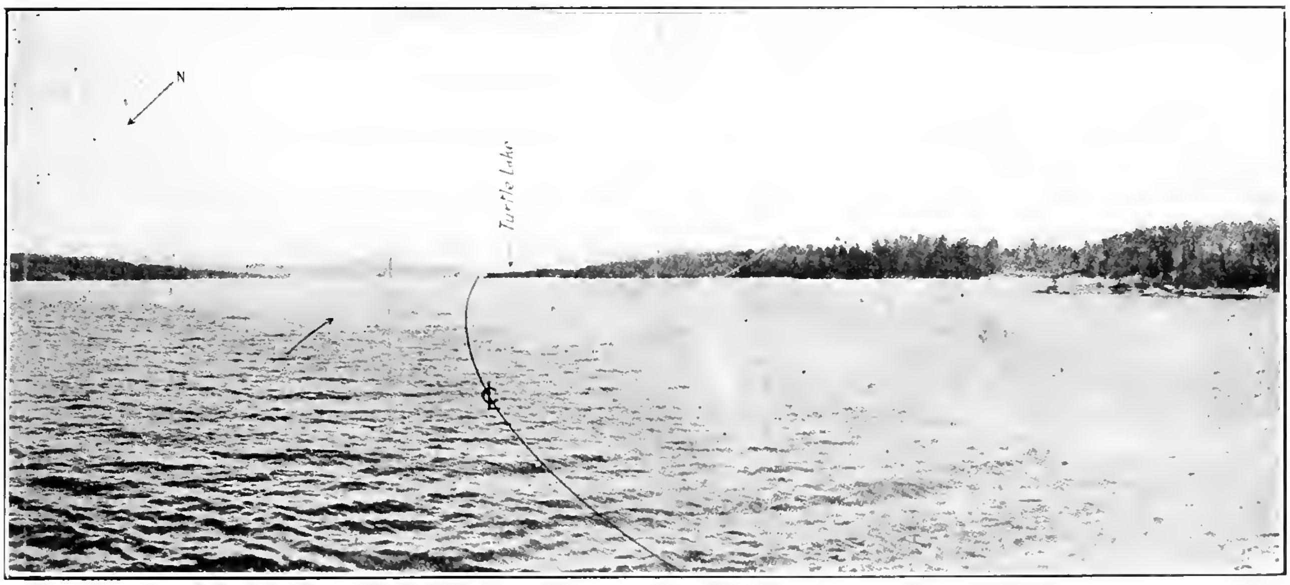

Fig. 1.—Summit at West End of Trout Lake.

It is the opinion of prominent Canadian shipping interests that Canada has little to fear from the improving of the Erie Canal route, or, indeed, any transportation route that the United States can construct, if she takes but full advantage of the great Montreal resources which Nature and Providence has given her.

Canada has the control of the bulk of the export and import trade of the great North-West of the continent if she should want it, as a glance at the accompanying map will show.

Trade will always take the shortest and cheapest route. This being the case, it is clear that if Canada has such a route its proper use will ensure her the trade, and this we find in the proposed Georgian Bay-Ottawa-Montreal waterway, usually known as the Georgian Bay Canal.

The survey, which was completed two years ago, required nearly three years' hard work by a competent staff of engineers. It has been completed in such a detail as not only to determine the most economical and feasible route, but to afford ample data for a close estimate of cost.

Commencing at Georgian Bay, the line proceeds up the French River by one of its five estuaries, known as the French River Channel, to the village of that name, where the first lock is encountered. By this lock the line is taken into the Pickrel River, which is followed for 37 miles to the second lock, then a lift of 24 feet brings the canal again into the French River. This stream is utilized for a distance of 14 miles to the third lock. Another lift of 24 feet at this

point and then comes a stretch of practically free navigation in Lake Nipissing extending 32 miles, at the end of which is a lock that elevates the east-bound craft from Lake Nipissing into Trout Lake. Here the summit is reached, 677 feet above sea level, and 24½ miles long, mainly free navigation, but requiring small cuttings at places where the channel is contracted. The channel leads directly into Lake Tallon (an expansion of the Mattawa River) which is to be raised 37 feet by a dam constructed at the head of Tallon Falls. The summit level, therefore, extends from Trout Lake to Tallon Falls. The run-off from the drainage area supplying this level, however, was not deemed, by the engineers, to be sufficient to work the canal system to its full capacity, and a painstaking search for additional supply was instituted. The river Amable du Fond, flowing northward, empties into the Mattawa lower down, and it was found that transportation of supplies, etc., so that the cost will be reduced to the minimum for this class of work.

From Mattawa to the city of Ottawa, below the Chaudiere Falls, there are 12 locks, with a total fall of 360 feet, and at three points locks are grouped in flights. One of these flights is to be at Ottawa to overcome the falls, a drop of 55 feet between the levels above and below the Chaudiere Falls. The other flights are to be at Chats Falls and the Rocher Capitaine Rapids. The single locks will be at Cheneaux Rapids, the Rocher Fender, the Paquet Rapids and Des Joachims.

From Ottawa to Montreal the main channel of the Ottawa River is followed, five single locks utilized to bring the proposed waterway to the level of the St. Lawrence. These locks would be at Hawkesbury, Point Fortune, Ste Anne and Verdun, and finally one opposite the custom house in Montreal.

Fig. 2.—Map Showing Advantageous Location of Georgian Bay Canal.

by means of a flume and tunnel it could be diverted so as to empty into the summit level, thus giving a large surplus of water.

Leaving the summit level the line passes to the north of the main channel of the Mattawa River, across quite a high divide and thence into the level below, through two flights of locks of 60 feet each, a drop of 120 feet. Following down the Mattawa, the Ottawa River is reached at the town of Mattawa. After a passage through three locks, one at Les Epines Rapids, one at Champlain Chute, above Mattawa, and one lock located at the town of Mattawa itself, a fall of 57 feet in the three, is a total drop of 177 feet from the summit.

This section involves the heaviest work of the whole line, but the close proximity of the line of the Canadian Pacific Railway eliminates the features of excessive cost of

On account of expected opposition to the adoption of the latter section of the route, because of the frequent crossings which it will involve of the trunk lines of railway centering in Montreal, another route which would obviate this difficulty has been investigated. It proceeds by the River Des Proiries lock of Montreal, and will debouch upon the St. Lawrence at Bout de Lisle, the descent being accomplished by three locks.

In all, the canal from Georgian Bay to Montreal will be 400 miles long. From Montreal to the summit the distance is 334 miles, with a difference of 659 feet in elevation; and from the summit westward it drops 99 feet in 83 miles. The locks are to be of sufficient capacity to pass the largest freight boats on the lakes, vessels which are gradually approaching 625 feet in length, and are even now 60 feet beam,

with a carrying capacity of 12,500 tons on a draught of 20 feet.

Such vessels are capable of carrying over 450,000 bushels of grain. It is well known that from the head of lake navigation to Liverpool the saving in distance is nearly a thousand miles by the Georgian Bay Canal route, as compared with the Chicago-New York route, which also involves the disadvantage of a long carriage by the Erie, a mere barge canal. As compared with the St. Lawrence Canal route, the Ottawa and Georgian Bay Canal would effect a saving in distance of nearly 400 miles in the transportation of grain from the lakes to the head of the Atlantic navigation. This would mean a saving, on an average, of nearly 34 cents per ton, and about 1 cent per bushel in wheat, in favor of the Ottawa route.

Last year between sixty and seventy million bushels of wheat alone were transported by vessels via the existing longer routes. The magnitude of the traffic in which the new canal would participate under advantageous conditions may be further estimated from the fact that the value of freight passing through the Soo canals amounts to more than $600,000,000, upon which the freight earnings amounts to $40,000,000.

The size of the Georgian Bay waterway and of the locks was determined from considerations turning on the present traffic on the Great Lakes. There would obviously be no advantage in designing the canal to deal with a larger class of boat than is able to pass the Sault Ste. Marie Canal, joining Lake Superior with Lake Huron. The depth over the sills and the channels leading to the Sault Ste. Marie locks, as well as the depth of water in the terminal harbors, at present limit the loading draught to 20 feet, so that it was felt that a depth of 22 feet, as fixed for the Georgian Bay Canal, would meet present requirements and allow a slight increase of draught for the future.

Starting from Port Arthur, the distance to Montreal via the proposed canal is 934 miles, via Lake Erie and Welland Canal, 1,216 miles; via Buffalo and Erie Canal to New York, 1,358 miles, giving a difference in favor of the projected canal of 282 miles, as compared with the present St. Lawrence route, and of 424 miles as compared with Buffalo and New York route.

Fort William to Liverpool, via Georgian Bay Canal ....4,123 miles
Fort William to Liverpool, via New York........4,929 miles

Giving a difference of 806 miles in favor of the Georgian Bay Ship Canal.

Taking into consideration the delays caused by passing through the restricted channels where the speed of vessels has to be reduced, and allowing forty-five minutes for each lockage, it is computed that the time of transit from Georgian Bay to Montreal will be about seventy hours, or one and one-half days faster than any existing water route from the head of the Great Lakes to an ocean port. The canal cutting for the entire route is twenty-eight miles. The length of submerged channels to be excavated is sixty-six miles, and there is, apart from the above, an aggregate of 14½ miles where obstructions, such as shoals, sharp bends, etc., have only to be removed to give very wide channels. Therefore, of the 440 miles of this waterway 108 miles requires excavation, leaving 332 miles of natural channel in lakes and rivers which will only require the raising of the water in the way of improvement. The length of the season of navigation is estimated 210 days.

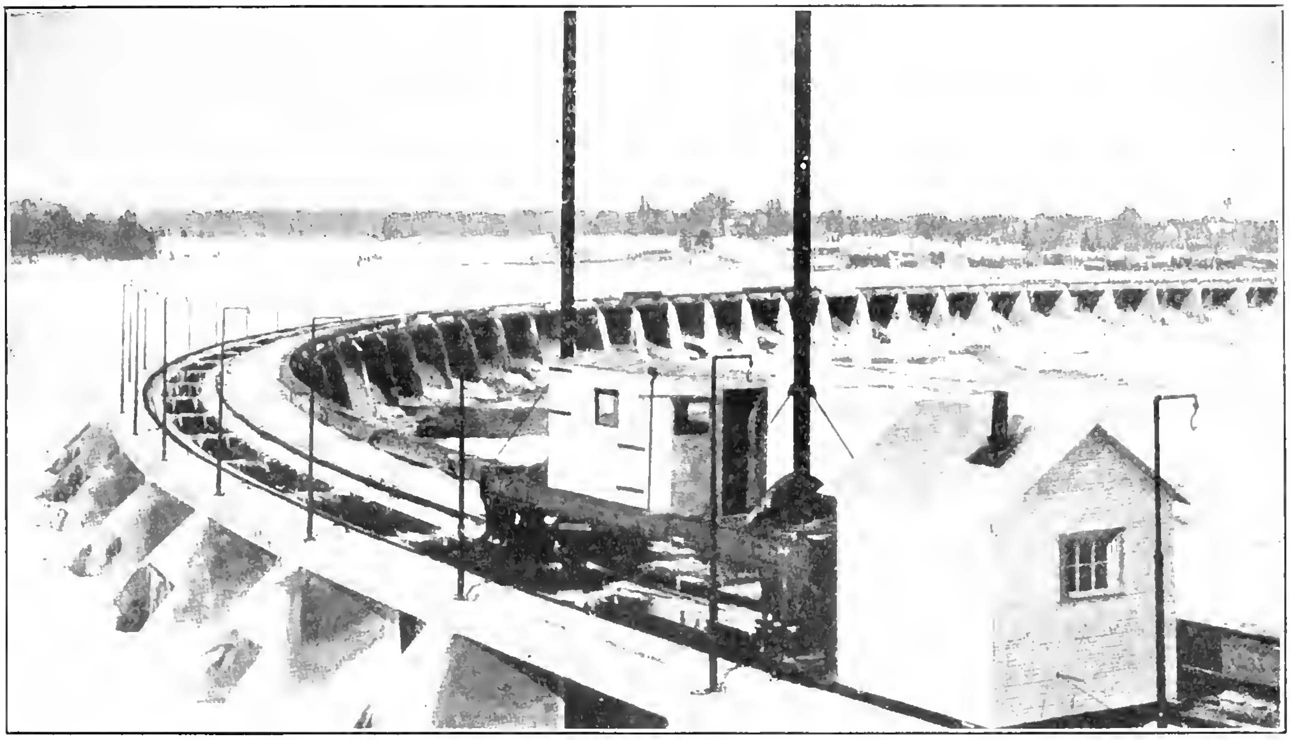

Fig. 3.—Chaudiere Regulating Dam, Ottawa River.

It will be necessary to build forty-five dams for navigation purposes alone in connection with the undertaking. Many dams will be required for storage purposes.

The development of electrical power is another important consideration in connection with the construction of the Georgian Bay Canal. A conservative estimate places the water-power development which will be rendered available by navigation dams at 1,000,000 horse-power.

One of the most important features of the projected undertaking, affecting the city of Ottawa particularly, is the regulation of the water supply of the Ottawa River. The range of flow of the Ottawa, at the city of Ottawa, is from a maximum of 194,000 cubic feet per second to a minimum of

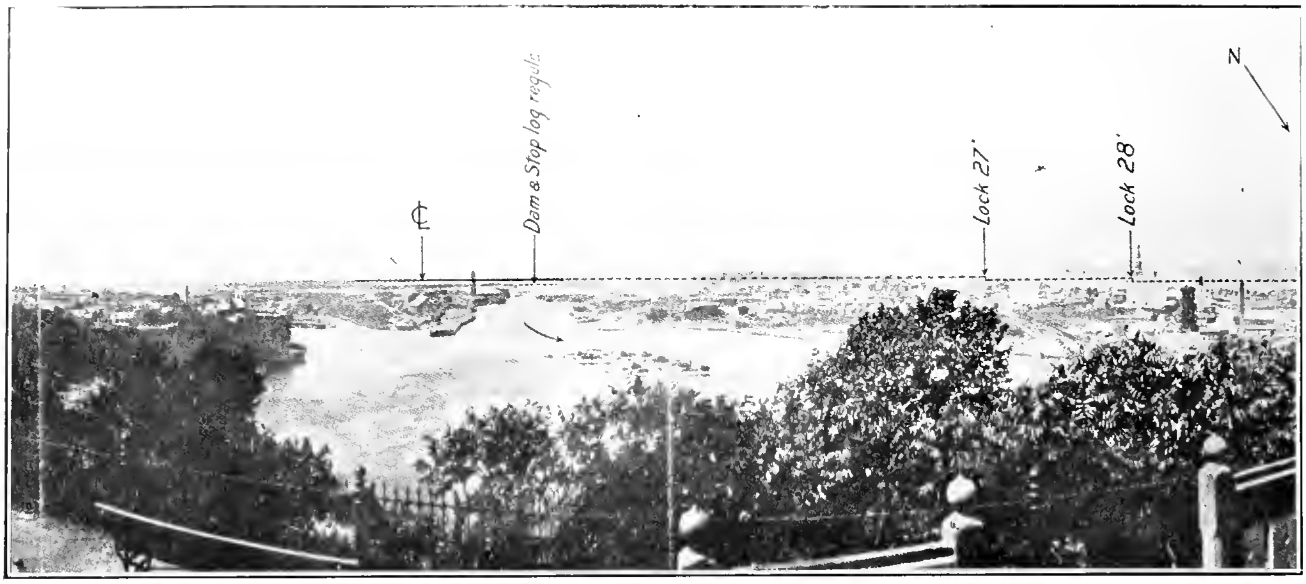

Fig. 4.—Hull, Quebec, Showing Canal North of City.

12,000. By the system of dams and reservoirs required for the operation of the canal, a mean flow would be maintained the year round.

Estimates of the approximate cost of the canal which have been given out of late will be found to be based upon mere guess-work, and superficial knowledge of the ascertained conditions. None of these, it may be taken for

Fig. 5.—Eastern Entrance to Canal, Montreal Harbor.

granted, has been authorized by the department of public works, under whose auspices the survey has been conducted.

These estimates have placed the cost at about $105,000,000. This, it is believed, is over five per cent. in excess of the actual estimate based upon the completed survey.

Montreal is, according to the latest statistics, entitled to rank second city in shipping of all the cities on this continent, and the Federal Government has, during the past fifteen years, expended large sums in improving the ship canal, so to speak, between Montreal and Quebec. To complete a channel from Montreal to the sea, 30 feet deep at lowest tide, it is estimated that 75,000,000 cubic yards will have to be removed, a great portion of which has already been done.

The opening of this Georgian Bay Canal would open a trade between the West and the Maritime Provinces and Newfoundland, which is much to be desired; the west and the east having . . . that they ought to interchange if given such cheap transportation as the Georgian Bay Canal would give. It would make the Ottawa River and its tributaries a great channel of watercourse between Montreal and the country lying at the head waters of the Ottawa River in the provinces of Quebec and Ontario and between them and Hudson Bay.

The opening of the canal to the head of Lake Superior would prove to be an incentive of a great further series of canals and waterways through the Lake of the Woods, Lake Winnipeg and Saskatchewan River to Edmonton, so giving Canada a waterborne system right to the very heart of the continent, which would create new business and new activities along the whole route by the enormous electrical power that would be developed by the construction of the canals—power that would in a short time result in the building up of manufactures where success might almost be guaranteed, seeing that they would possess almost the cheapest motive power and transportation that it is possible to make.

THE RED AND BLACK ROADS OF SASKATCHEWAN.

During the fall of 1912, Prof. W. W. Andrews, M.A., LL.D., at the instance of the Provincial Board of Highway Commissioners, conducted laboratory and other investigations into the qualities and possibilities of Saskatchewan clays as materials for road making. The following is a condensed report of Dr. Andrew's work and findings prepared by himself. Having been carried out only on an experimental scale during last summer, it is not possible as yet, of course, to determine just what the practical value of the results described will be. That can be fully determined only when the roads have been subjected to several years of wear and cost of upkeep estimated.

Very little experimental investigation was necessary to establish the fact that at a comparative low temperature the clays of the prairie almost without exception will burn to a porous, gritty material, the properties of which are a direct opposite of the corresponding ones in the clays. The clays are nearly impervious to water, especially when well puddled, the clay clinker is readily porous; the clays are weakest when wet, the clinker is stronger; the clays do not wear to a dust, the clinker will; the clays expand when moistened, the clinker powder shrinks; the clays are adhesive, the burnt clay is not, and the clinker varies in color from reddish yellow through a brown to a bright rouge, great contrast to the slaty colors of clays.

It became evident that if this clay clinker can be produced at a cost sufficiently low, we would have a material which we could use to mix with the clay to counteract its troublesome qualities and which would prove of immense service in making roads in those parts of the province remote from sand and gravel beds. In some parts of the province natural mixtures have been made of sand and clay, and good roads in all seasons of the year are the result—witness many sections in the neighborhood of Estevan and Weyburn in the Duck Lake region. The mixture which has been chosen in this experimental work is one part of raw clay to four parts of clinkers, with the expectation that from untreated portions of the road clay will be carried on by the wheels of vehicles and dropped upon the clinkered section. There is danger that at first muddy wheels will tear up sections of clinker until the road has become properly mixed and compacted through traffic. In such a mixture the clay will keep it dustless and strong during dry weather, and during wet weather the sharp nature of the clinker will hold the wheels up, while at the same time the porosity will permit the excess of moisture to drain out of the road surface very readily. In these respects the clinker will be superior to sand and gravel because it will absorb a larger percentage of moisture before it appears to be wet. Experiments with clay taken from Albert Street, Regina, show that clay containing 30 per cent. of moisture will pack to a tough resistant mass, and observation of traffic showed that at this percentage the clay packed solidly under the wheels.

Experiment also showed that by using good coal the clinker could be produced at an economical rate, and that straw would give sufficient heat for this purpose. It remained to be demonstrated that the straw (the fuel universally abundant throughout the settled portions of the province) can be used for producing clinker at a rate sufficiently cheap. The great handicap to this form of fuel is found in the fact that a fireman needs to be in constant attendance upon a kiln during the burning. How this works out will appear in the analysis of costs at the conclusion of this article.

This much having been done, Mr. A. J. McPherson, chairman of the Board of Highway Commissioners, decided to lay out a piece of experimental road. North Winnipeg Street, Regina, was chosen, where already an experimental stretch of clay and gravel road was being laid down. Mr. J. E. Milne took charge as engineer of the work.

As the designer of the road Prof. W. W. Andrews named it the Red Road of Saskatchewan. First a trench was dug along the centre of the road to an average depth of two or two and one-half feet and a three inch tile laid down, covered to a depth of one inch. The trench was divided in sections six feet long and each section was used as a furnace. This plan had the great advantage that it burnt the sides of the trench, thus producing two porous sheets of burnt clay, extending from the surface down to the tile. It also clinkered the clay covering of the trench and a portion of the road to each side of the trench. Much time and expense was given to this side burning, but while with a steady fuel, left for a few days to burn itself out, the side burning was all that could be desired, we were defeated in our attempts to accomplish this in any adequate way with the straw fuel.

The central underdrain adds very considerably to the first expense of construction, and it has this defect that it weakens the road bed for a year until the filling has settled down. On account of the permanent nature of a well laid underdrain but one-tenth of its cost should be charged against the first cost of the road, and once laid down in proper manner it will last as long as the road is used. Moreover, if it be opened to the side ditches by drains to alternate sides of the road, every two hundred feet or so, the prairie winds all summer long will suck the air through the heart of the road bed and reduce its moisture to at least 13 per cent. This is the percentage of moisture found in clay from a wheel track on Albert Street, Regina, dug from under the snow. At this percentage the clay possesses great compressive strength; if packed it will be almost as hard as marble, when frozen it will shrink but little, and when thawed out will not soften. A road bed dried out and kept dry will in time of rain be capable of absorbing hundreds of tons of water per mile, before it reaches the dangerous limit of 30 per cent. The porous clinker in the surface metalling of the road will permit the water to spread rapidly from the surface into the bone dry bed ready to receive it, and then to the central drain. When a road has been constructed in this way each wheel track becomes a watershed, from which in two directions any excess of water may flow rapidly, to the outside ditches on the one hand and to the central underdrain on the other.

Until a method be found for cheaply calcining the sides of the trench it will be better to dig the trench as narrow as possible and fill it with burnt clinker. One of the firms manufacturing mechanical ditchers is preparing estimates of a machine costing in the neighborhood of $1,500, which will cut a six or eight inch trench to the required depth,

and mechanically deposit the tile in the bottom. This will reduce the cost of digging and it will require but little clinker when mixed with one-half its amount of raw clay to fill the trench. The after settling will be greatly reduced when the trench is so filled.

After the drain is completed the grading is done in the usual way and the surface rolled. If left to be puddled and packed by traffic the clay, even to the sods from the road side, which is the most difficult material to treat, is compacted sufficiently to be broken up by the plough into hard lumps ready for the kilns.

Preparing the Clay Clinker.—The method of the burning the clay is as follows: Iron crates were made to provide a fire box and over these the lumps of clay made by breaking up the roads which had been graded and rolled are piled. In practice it will probably be well to grade the road and leave it for a month or so for the traffic to pack and then begin the burning. Prairie sods will form good clinker only when it has been puddled and packed, as a rain and subsequent traffic will do it. The addition of salty water to the sods improves the clinker.

Eight hours firing produces a fine mass of clinkers, from two to two and a half cubic yards being produced in each kiln. A little straw is spread over the road bed and then the clinker is spread mixed with a little straw and the proper amount of raw clay. The straw serves several purposes. It prevents the clay of the under bed working up and ingulfing the clinker on the surface, and its juice has a remarkable power to lessen the shrinkage of the clay and to increase its tensile strength. It supplements the binding power of the clay which is mixed with clinker, and by its cushioning tendency it reduces the crushing effect of the traffic on the clinker. In fact it acts as the swaddling bands of the young road.

The last operation is the rolling of the road, and that thoroughly done, the road is ready for use.

Such a road should be comparatively dry fifteen minutes after a rain. It should never load the wheels, nor ever grow dusty, and if the split log drag or the lap drag be faithfully used it should prove a cheap and eminently satisfactory road. Just what it would require in the way of maintenance it is at present impossible to say. Probably if the drag be used as it should be, the addition of a couple of inches of fresh clinker to the central portion of the road once in five years will be all that is required to keep it in the finest condition.

It may be of interest to point out that the clinker will serve many other purposes. For private roads and paths in parks and door yards it will prove a beautiful and efficient material which will prevent the tracking of mud into the house. It will also be useful around schools and country churches, where the bright red color will show in pleasing contrast to the green of the grass. Ground fine it is a perfect substitute for sand in mortar, making a lighter and stronger plaster than sand lime mortar. It can be so treated that it will form a good filler for cement concrete and asphalt pavement. The homesteader can build a considerable portion of his house from the clay dug from his cellar, importing the lime only.

The Cost of a Red Road.—The cost of the first portion of the experimental road was $1.80 per lineal foot, the latter portion cost $0.82, and after checking over the figures with Mr. J. E. Milne, the cost is estimated as follows:

Two men at $2.50 per day tending five kilns producing and spreading 10 cubic yards of clinker per day	$5.00
Hauling straw	3.00
Oversight	1.00
Wear and tear of crates	.80
Cost of ten cubic yards of clinkers	9.80
Cost of one	.98
Therefore cost of metal per lineal foot	.33
Grading cost	.16
Total	.49
Which is equal to	$2,500 per mile
The underdrain costs	1,440 per mile

The total cost of clay clinker road underdrained and covered with eight inches deep of clinker and 12 feet wide will be $3,940 per mile. A gravel road with equal depth of metal costs $4,150 per mile, estimating material at $1.80 per cubic foot laid on road.

A mechanical ditcher will reduce the cost of underdrain to two-thirds the above cost, namely, $1,000 per mile. The drain once in will provide drainage and ventilation of the road bed. It may be found that the underdrain may with safety be omitted altogether. If so this will reduce the cost to $2,500 per mile.

If compact fuel such as coal be used, so that once charged and lighted a kiln may be left to burn itself out, two men could build, charge and open 15 kilns per day, and estimating the fuel at $9.00 per ton, a cubic yard will cost $0.47, and a lineal foot will cost $0.16, instead of $0.33 as above, while the cost of a graded road per mile will be $1,643 instead of $2,500. We may confidently expect that in every part of the province red roads without underdrainage can be constructed for about $2,000 per mile, and if we can cheapen fuel, as a future article will show to be possible, these figures will be somewhat further reduced, or at least made more certainly realizable.

The Black Road of Saskatchewan.—Briefly described this patent road is constructed as follows: The underdrain is put down and made to open every two hundred feet to alternate sides of the road. This secures sufficient drainage and effective ventilation, which ever way the wind blows. The road bed is graded, covered with three inches of straw and then sprinkled and puddled by traffic or by the use of a packer, or best of all by the feet of a few cattle driven back and forth along the road till the straw is tramped well into the mud. Then as it dries it is rolled until it gains that glistening surface and marble-like hardness so marked a feature of the prairie roads. The surface is then swabbed with a tarry asphalt and then three inches of asphalt is laid filled with powdered clinker and little slabs of clinkers, which when spread and rolled lie over each other in successive layers. This produces a schistose or layered structure, which will prove very strong per inch of thickness. The road may be made still stronger if chicken coop wire (one or two inch mesh) be laid on the tarry layer and the asphalt poured over it so that it becomes thoroughly imbedded in the asphalt sheet.

The little slabs are made by spreading clay on the surface of the pavement already constructed and passing the steam roller over it. They are then cut with a sharp spade or knife rake to the desired sizes, dried a little and burnt in a rotary calciner or crate. Being somewhat porous when mixed with hot asphalt, they suck in a small portion of the bitumen on cooling, and by this means become much stronger than stone of the same original hardness. The adhesion between the bitumen and the filler is perfect, being not merely a surface contact, but a surface impregnation.

It is hoped for streets in small towns and villages, the suburbs and annexes of large cities, for sidewalks, and in many cases for country roads this type of road will prove a strong, smooth, mudless and dustless road, easy to keep up and sufficiently cheap to be considered a practical proposition.

The cost cannot be accurately estimated till an experimental piece has been constructed. The burnt clay filler will cost no more than one dollar a cubic yard, where crushed stone costs $4.20 per cubic yard, and the filler constitutes five-sixths of the volume of asphalt pavement. To this great reduction in cost may be added that achieved by the omission of the base of cement concrete. On the other hand the preparation of the gumbo road bed will cost more than the graded surface on which the concrete sheet is laid, and to this must be added the cost of the underdrain which cannot be left out in the construction of a black road.

The future of the black road depends upon the answer which future experimental work may find for the question: "Will properly prepared gumbo form a reliable road base for heavy traffic if protected from moisture?" This we all know, that the naked gumbo in dry weather bears up in dry weather under the heaviest traffic. We should not expect it to prove weaker when waterproofed and protected by a sheet of heavily rolled asphalt.

ELECTROLYSIS FROM STRAY ELECTRIC CURRENTS.

By A. F. Ganz, M.E.

(Continued from page 556 of last issue.)

Damage and Danger Produced by Stray Electric Currents on Underground Piping.—It has already been pointed out that damage from electrolysis to underground piping usually results in the neighborhood of the power station from current leaving the pipe to flow to the rails and to other return conductors, and that service pipes in the same locality are most frequently damaged where they cross under and are positive to trolley rails. The destruction of underground piping by electrolysis is, however, by no means confined to the so-called positive districts in the neighborhood of the railway power station, but will occur at any point in the pipe where current leaves the pipe to flow to the surrounding soil In Fig. 10 is shown a water pipe and trolley line near a salt water bay, about 8 miles distant from the railway power station supplying this trolley road. The trolley rails at this point are about 25 volts positive to the water pipe; that is, the water pipe is in a highly negative district. The railway power station is located on the shore of a salt water bay, and its negative bus-bar is grounded through low resistance ground connections, so that large currents leak from the trolley rails at points shown in Fig. 10, and flow through the ground and the salt water of the bay to return to the negative bus-bar at the railway power station. These stray currents in their path encounter the water pipe and flow part of the way thereon. The values of current indicated on the pipe are average values obtained from 24-hour records. It is seen that in one section large currents leave this water pipe to flow to the surrounding soil and from there to the salt water. An examination of the pipe at this point also indicated that it had been badly corroded by electrolysis This, therefore, affords an excellent example of destruction by electrolysis of a water pipe in a highly negative district.

In Fig. 11 is also shown a water main and service pipe crossing under trolley rails and under telephone ducts. At this point the pipe is also negative to the trolley rails, but positive to the lead sheaths of the telephone cable, the potential condition with reference to the cables being caused by the fact that the telephone cable sheaths are bonded to the railway return conductor at the power station, As shown in the diagram, current flows from the rails to the water pipe, and leaves the water service pipe where it crosses under the telephone ducts to flow to the cable sheaths, resulting in the destruction of the service pipe. An examination showed pits extending entirely through the service pipe, directly under the telephone ducts and facing the ducts. This, therefore, affords another illustration of destruction of a service pipe in a negative district.

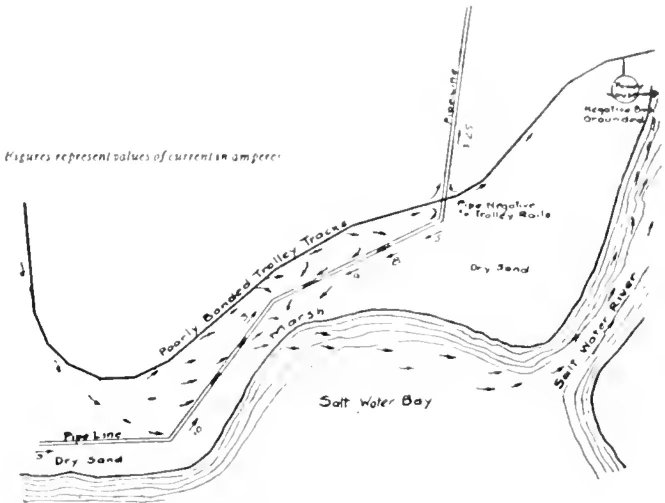

Fig. 10.—Diagram Showing Stray Current Leaving Water Main in Negative District.

Besides danger from electrolytic destruction of the pipes, stray currents, where they flow on underground piping systems, frequently enter buildings through service connections and produce a serious fire hazard. For example, current may flow into a building through a water service pipe, then flow from the house water piping to the house gas piping, and then out from the building through the gas service pipe. An example of this kind frequently met in practice is illustrated in Fig. 12. Such contacts between service pipes, or between a service pipe and the lead sheathing of a telephone or a power cable, frequently occur through metal ceilings,

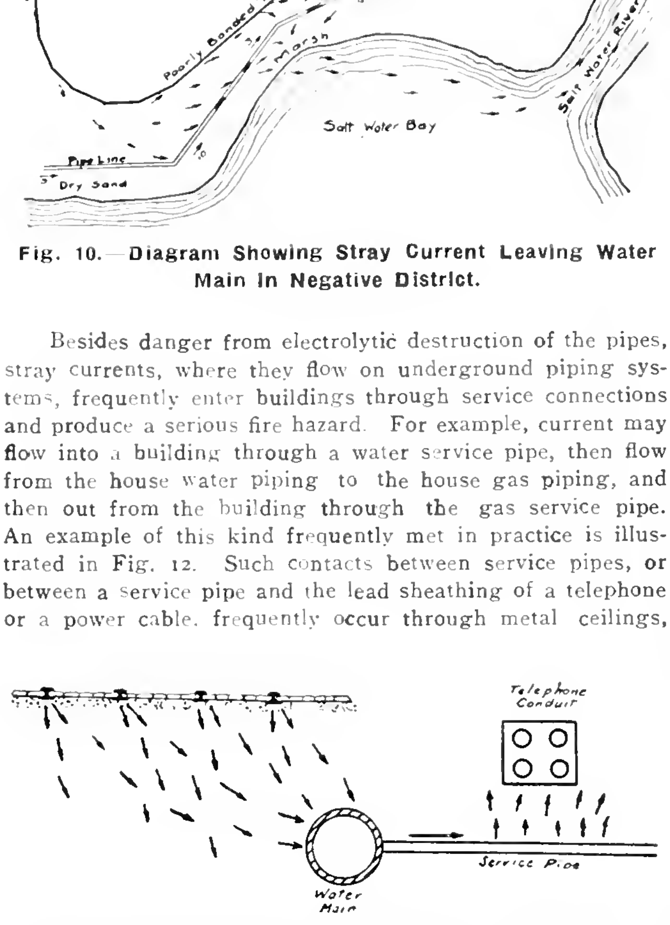

Fig. 11.—Example of Service Pipe Negative to Trolley Rails and Destroyed by Electrolysis Due to Currents Flowing from Rails to Pipe and from Pipe to Telephone Cable Sheaths.

or where the pipes rest against each other. Since dangerous heating may be produced where the current flows through such contacts, or where vibration may momentarily separate the contacts and produce an arc, nearby inflammable material is in danger of being set on fire. The author has in fact found many cases where currents up to 30 amperes were flowing into-and-out of buildings through service pipes or lead cable sheaths. Evidences or arcing having occurred between such contacts in buildings have also been found. There is no doubt that many fires have started in this way, but it is always difficult to prove the cause of a fire because of the destruction resulting from the fires.

Corrosion Not Caused by Electrolysis.—While electrolysis is undoubtedly responsible for much destruction of underground piping and other underground metallic structures, the author has frequently been asked to examine cases where the destruction had clearly not been produced by electrolysis from stray currents, but by altogether different causes. It must be remembered that corrosion of a metal from electrolysis can only occur where current leaves the metal to pass to an electrolyte, such as damp soil. Service pipes have sometimes been found destroyed inside of cellar walls where they were not in cantact with an electrolyte; the corrosion here is purely of a chemical nature, and not in any way chargeable to stray current electrolysis. Brass or copper pipes and fittings and brass condenser tubes in contact with salt water also corrode quite generally, but this is

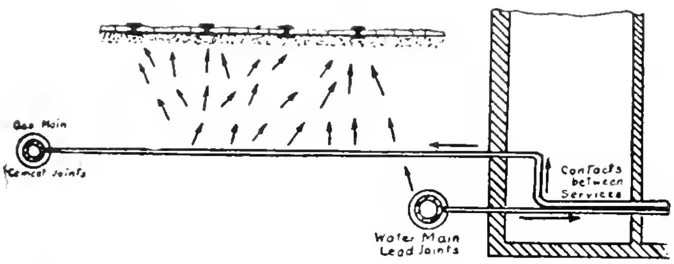

Fig. 12.—Showing Stray Currents Entering and Leaving Building Through Service Pipes and Causing Fire Hazard and also Destroying Gas Service Pipe by Electrolysis.

caused by electrochemical action of the salt or contaminated water upon the metal, and not by electrolysis from stray currents.

Remedial Measures.—The only one complete remedy for electrolysis is the use of a completely insulated return circuit. Such railways may be provided with double overhead trolley wires, as used (for example) in Cincinnati and Havana, Cuba; or with an insulated outgoing and return conductor in underground conduits, as used (for example) on the surface lines on Manhattan Island and in Washington, D.C.; or with separate insulated third and fourth rails for the outgoing and return current, as is used on the Metropolitan District Railway in London. With these systems the running tracks are not used as a part of the electric circuit, and as both positive and negative sides of the circuit are insulated no stray currents are produced.

Where a road operates on private right-of-way the rails can often be practically insulated from ground and the escape of current from the tracks prevented. For surface roads this can be practically accomplished by placing the rails on wooden ties above ground, using broken stone for ballast and keeping the rails out of contact with ground. In the case of railway lines operating on elevated structures the rails can be fastened to wooden ties and kept out of contact with the structure. These rails, supplemented where necessary with negative feeder cables, also insulated from the structure, can then be used for the return conductor. In this way the return circuit is quite thoroughly insulated from the elevated structure and from ground, and stray currents are entirely prevented.

A number of remedial measures intended to reduce stray currents from electric railways using the grounded rails for a return conductor have been tried. These methods may be divided into two classes, the first class aiming to remove the current harmlessly from pipes by metallic connections or bonds between the pipes and the railway return circuit, the second aiming to minimize stray currents through ground.

Since stray currents cause damage only where they leave pipes to flow to the surrounding soil, attempts are frequently made to prevent destruction from electrolysis by connecting or bonding the pipes or other structures by means of metallic conductors to the rails or to the negative return circuit, so as to remove the electric current by metallic conduction and thus prevent corrosion from electrolysis. As the lead sheaths of underground cables form continuous and uniform metallic conductors, it is, therefore, possible to protect such cable sheaths against electrolysis by bonding or connecting them to the railway return circuit. This practice is, however, exceedingly objectionable because by such bonding the trolley rails are paralleled by a low resistance grounded conductor which greatly increases the tendency for current to flow through ground from the tracks. The second objection is that such bonding makes the cable sheaths negative to all other underground structures, such as water and gas pipes, thereby setting up a tendency for current to flow from such pipes to the cable sheaths. This effect is illustrated in Fig. 13. In this a case is shown, frequently found in practice, where the pipe is everywhere negative to the trolley rails, except in a very restricted area in the immediate vicinity of rail feeder connections, but is everywhere positive to the underground cable sheaths. The pipe is consequently everywhere in danger from stray current flowing from the pipe to these cable sheaths. In one city, in fact, where there was an underground cable system with its lead sheathing bonded to the railway return circuit, it was found that the underground pipes were everywhere negative in potential to the trolley rails, and were, therefore, considered immune from electrolysis. An investigation showed, however, that these pipes were at all points highly positive to the underground cable sheaths and were in fact in considerable danger from electrolysis. It has been frequently found that, where gas or water service pipes cross bonded cable sheaths, currents are caused to flow from the service pipes to the cable sheaths, and produce gradual destruction of the service pipes. A case of this kind was illustrated in Fig. 11. In the case of one city 19 service pipes were destroyed in the course of one year directly where these pipes cross telephone ducts containing cables whose sheaths were honded to the railway re-

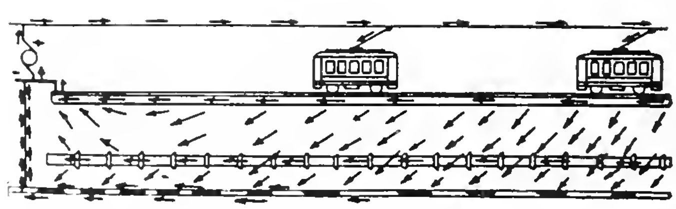

Fig. 13.—Showing Path of Stray Railway Currents and Showing Effect of Bonding Underground Lead Cable Sheaths to Negative Bus-Bar of Power Station.

turn circuit. This method of bonding, therefore, protects continuous conductors like lead cable sheaths, but at the expense of other underground metallic structures which cannot be so treated. Its effectiveness as a protective means depends absolutely on uniformity of conductivity of the conductor to be protected, but it is not generally applicable to underground piping systems, because the latter do not form continuous electrical conductors, but are more or less discontinuous networks. While lead calked joints usually have a relatively low resistance, it frequently happens that they develop such high resistances as to make them practically insulating joints, due undoubtedly to the formation of oxide coatings. Cement joints and cement pipes have such

a high resistance compared with iron pipes that they are practically insulating.

Bonding of pipes to the rails or to the negative return circuit can only afford local protection to the extent that the piping connected forms a continuous metallic conductor, and this latter is an unknown and indeterminate quantity in a piping network. In the practical working out of a bonding or drainage system two opposing tendencies develop; first, there is a reduction in the difference of potential between pipes and rails in the positive areas, and consequent reduction of damage in those areas; and, second, there is an increase of current flow on the pipes throughout the entire system, thus increasing the danger of trouble at high resistance joints, or other places where two piping systems or separate portions of the same system are electrically discontinuous. As a rule, in the early stages of this system, and especially in small networks when there are comparatively few bond connections, and the resistances of the paths over the pipes are, therefore, relatively high, the effect is apt to be beneficial, reducing the danger in positive areas more than it increases the danger elsewhere. As the system grows and the load increases, more and heavier bonds become necessary. The current on the pipes may finally become so great that the trouble from current shunting around joints, or between separate systems, will increase more rapidly than the danger in the positive areas is reduced, and any further increase in the bonding becomes an actual source of danger to the system. Since bonding transfers the trouble from the region where it was most evident to a new locality where it may require several years to manifest itself, the false impression is created that the trouble has been removed. It is due largely to this obscure manner in which trouble develops that has caused this method to become quite widely used. A number of cases have, in fact, been reported where a main bonded to the negative return circuit at the power station was completely destroyed by electrolysis a block or two away, because of a high resistance joint in the main forcing current to shunt around the joint and leave the main a short distance away from the power station. A case of this kind is illustrated in Fig. 14. In another case, the water main on one side of the street was bonded to the negative return circuit at the power station, and a main on the opposite side of the same street, although connected through cross-piping to the bonded main, was completely destroyed because high resistance joints had developed in the connecting pipes.

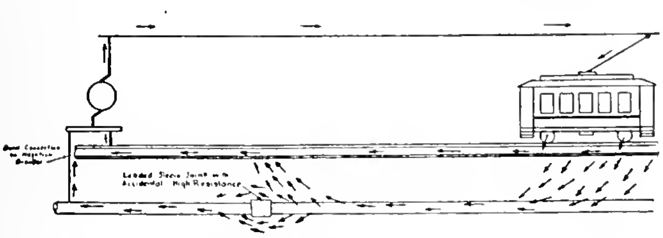

Fig. 14.—Showing Increased Danger from Electrolysis from Bonding Pipe to Rails, Caused by Accidental High Resistance Joint in Pipe.

Among the methods which have been used to minimize the escape of currents on systems using the grounded rails for the return conductor are increasing the resistance between rails and ground, increasing the resistance between pipes and ground, increasing the resistance along the line of the pipe by means of high resistance joints and decreasing the drop in potential in the grounded rails.

The resistance between rails and ground can often be increased by using broken stone ballast, whereby the rails are kept out of contact with ground, and water is allowed to trickle away from the rails, thereby maintaining high resistance between the rails and ground. Where an electric railway owns its own right-of-way, it is frequently feasible, as already stated, to practically insulate the rails from ground.

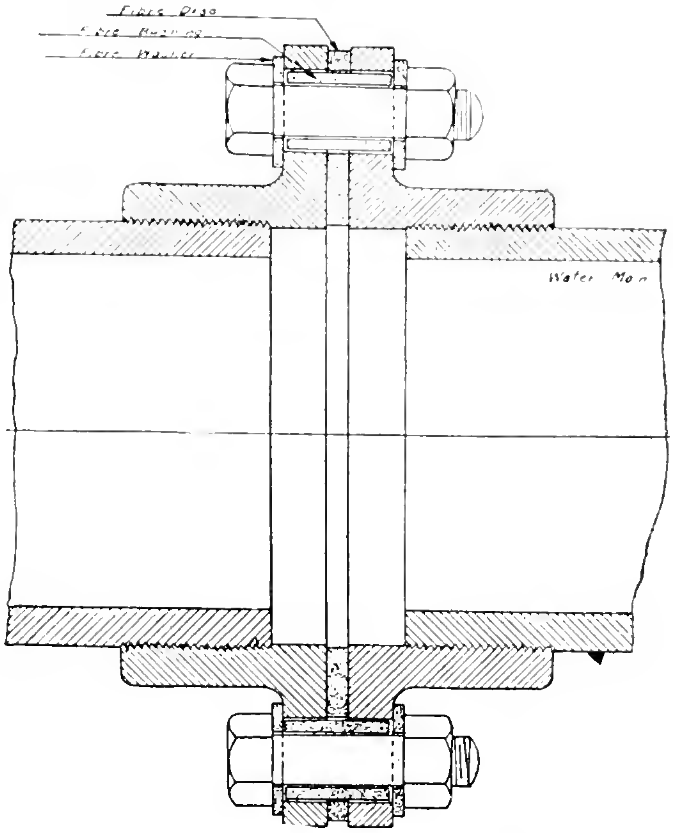

Fig. 15.—Section of Macallen Insulating Joint for Service Pipe.

Attempts have been made to insulate pipes from ground by paints, dips and insulating coverings. Experience, as well as a large number of tests on such paints and dips have, however, shown that no dip or paint will protect a pipe against electrolysis in wet soil. The first difficulty is the mechanical one of applying the paint so as to form an absolutely perfect coating, and then to prevent mechanical damage to the coating. Where imperfections exist or develop aggravated trouble always ensues. Experience further shows that, even where paints or dips are apparently intact and perfect, electrolytic action is not prevented; and, in fact, very serious electrolytic pittings have been found under apparently good coatings. It has been found that in most cases the coatings applied have either been completely destroyed by the effects of the wet soil and the electric currents, or defects in the coating have developed causing concentrated corrosion at such defective spots. The destruction of paints in wet soil, where subjected to an electric current, is due to traces of moisture finding their way through the coating, giving rise to the flow of a feeble current and resulting in a very slight amount of electrolysis. The gas and other products of electrolysis then form blisters and finally rupture the coating. Pipes in positive districts covered with imperfect insulating coatings, are in greater danger from electrolysis than bare pipes. Coating pipes in negative districts with insulating covering does some good in reducing the amount of stray current which reaches the pipes. Where it is attempted to apply a heated material, like pitch or as-

phaltum, to a cold pipe, it is impossible to completely cover the pipe. The only kind of insulating covering which appears to afford certain protection is a layer of at least 1 or 2 inches of a material like coal tar pitch or asphaltum, of such a grade that it is not brittle and so will not crack, but yet is hard enough to remain in place. The best way to apply such a layer is to surround the pipe with a wooden box, support the pipe upon creosoted blocks of wood, or upon blocks of glass, and then fill the space between the box and pipe with the molten material. As a further protection an insulated coupling should be introduced at each end of the section, covered so that, even if the covering should become defective at any point or points, no current can reach the pipe to corrode it by electrolysis. A pipe treated in this way, with the work done so as to be mechanically perfect, would undoubtedly be protected from electrolysis. However, the cost of carrying out such an installation is absolutely prohibitive, except in a few special cases, such as service pipes in very bad localities, or in the case of some very important individual pipe lines of small size. It is not sufficient to apply the covering only in the positive district, nor on the

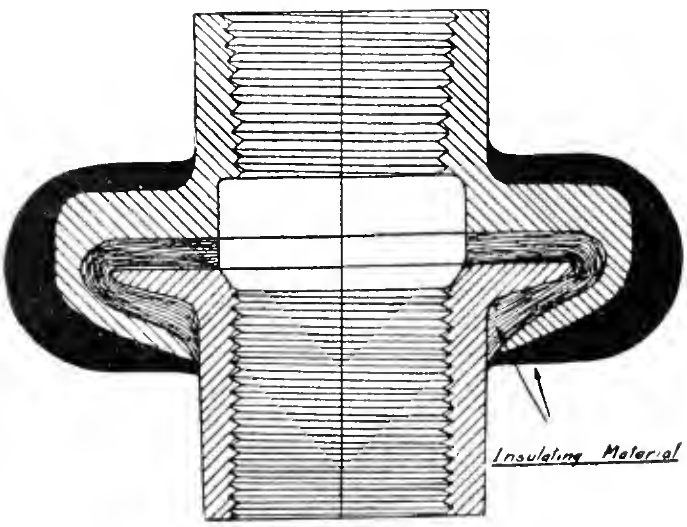

Fig. 16.

other hand, is it always necessary to cover the entire length of line. The portions which must be insulated can only be determined by properly conducted electrical tests. Experience has also shown that embedding a pipe in cement or concrete, even if this is several inches in thickness, does not protect the pipe from electrolysis, and in some cases it has been found that the pipe in concrete is destroyed at least as rapidly as when it is buried in ground.

Current flow on pipe lines can also be practically prevented by using insulating joints for every joint. Cement joints as ordinarily made do not generally produce metallic connection between the two pipes, and may practically be classed with insulating joints. The cause of the high resistance of cement joints is probably due to the fact that, although every attempt is made to push the spigot end home into the bell when laying cast iron pipe, as a matter of fact in most cases the two pipes are not in metallic contact. Even where there is metallic contact this is probably over a comparatively small area, if not at a point. As the end of the spigot is always heavily coated with scale, such metallic contact generally forms a poor electrical connection of comparatively high resistance. It is a simple matter to positively prevent metallic contact by inserting a ring of some cheap insulating material, such as fibre or cardboard, between the end of the spigot and the interior of the bell, and this has been done in some cases. The resistance of cement joints is, then, the electrical resistance of the cement intervening between the spigot and bell, and while cement is not an insulator, but, on the contrary, is probably as good a conductor as ordinary soil, yet, compared with iron, the resistance is so high that the cement joints practically interrupt the electrical continuity of the pipe line. A pipe line laid with all cement joints or with all insulating joints is, therefore, a discontinuous electrical conductor and is not capable of carrying stray electric currents. Such a pipe line, therefore, cannot pick up current in an extensive negative area to discharge it in a restricted positive area, which is generally the cause of the most serious electrolytic danger. For this reason a piping system with all cement or insulating joints is, on the whole, much less likely to be affected by electrolysis than a piping system with all lead or screw coupling joints. Experience has shown, however, that a cement jointed piping system is by no means immune from electrolysis, and there is abundant experience which shows that cement jointed mains, and especially service pipes from such mains, can suffer severely from electrolysis. In these cases the stray currents reach the mains and service pipes from other pipes or by other paths. An example of a gas service pipe from a cement jointed main destroyed by electrolysis from stray currents which reached the gas service pipe from the water piping is illustrated in Fig. 12.

A convenient form of insulating joint for small wrought iron or steel pipes is the Macallen, illustrated in Fig. 15. This is very largely used for insulating water and gas service pipes. A convenient form of insulating joint for large pipes is illustrated in Fig. 16, where a flanged joint is shown with a fibre disc between the surfaces of the flanges, the bolts being insulated with fibre tubing and the bolt heads and nuts insulated with fibre washers. This form of flanged insulating joint has been very largely used for water and gas mains. The Dresser insulating joints are also very satisfactory. Insulating joints can often be used to great advantage in special cases; as, for example, in the case illustrated in Fig. 12, where an insulating joint in the gas service inside of the building would protect the gas service pipe by preventing the current from flowing out of the building on this pipe. Insulating joints on mains must, however, be used with very great caution, as they can under unfavorable conditions do more harm than good. It is sometimes possible to use comparatively few insulating joints to break up the electrical continuity of a pipe line and protect the pipe line from electrolysis, but such joints must be installed only after careful tests have shown that the current is not likely to shunt through ground around them. This depends largely upon the potential gradient through ground and upon the electrical resistance of the ground.

(To be continued).

FORT GARRY HOTEL.

The Fort Garry Hotel, Winnipeg, is the recipient of probably the largest single shipment ever sent from the Amherst plant of the International Engineering Works, Limited. This hotel, which is being erected by the Grand Trunk Pacific Railway is to have a complete power plant furnished by the above company. It will consist of four 300-horse-power Robb-Brady Scotch boilers and three vertical high-speed cross compound engines with two duplex air compressors, smoke connection for the boilers, and auxiliary apparatus. The boilers weigh 32 tons each, are 10 feet in diameter by 17 feet long, with double furnaces 4 feet in diameter by 14 feet 2 inches long.

REINFORCED CONCRETE DESIGN.

The subject of reinforced concrete design and the question of economy in same is well treated by Mr. J. A. Davenport in a paper given before the Concrete Institute of London, England. The following abstract from the above paper gives the conclusions arrived at from the working out of tables presented to the institute by Mr. Davenport:—

Economy in reinforced concrete design might be discussed with regard to: (1) The engineering structure, (2) the architectural structure, and the two sets of conclusions might or might not coincide. The completed engineering structure was a skeleton frame, without any architectural finishes, embellishments, fittings, etc.; while the completed architectural structure was the engineering structure made ready for use and presentable to the eye by the addition of finishes, fittings, embellishments, etc. There were, of course, certain structures such as retaining walls, bunkers, harbor works, etc., which are engineering structures purely and simply, and could not well be considered from an architectural point of view. But it was the object of the paper to deal chiefly with the structures composed of beams, columns, slabs, and walls, which came under the head of architectural structures. The most economical reinforced concrete engineering structure would have a certain arrangement of slabs, beams, columns, etc., with definite percentages of reinforcements, such arrangement and percentages having been determined, with due regard to the loading, with a view of producing the cheapest possible skeleton structure. This result would probably be attained by keeping the slab thicknesses small by the introduction of beams, by keeping beams deep and narrow, and by having the size of columns (probably all different) just sufficient to carry the loads. The adoption of such a scheme would result, as already stated, in the most economical engineering structure; but if they considered the salient engineering points from an architectural point of view, they might find the nett results economical in some cases and very uneconomical in others. Generally speaking, it was economical to reduce the thickness of the slabs by introducing beams and keeping the spans small. Now, it often happens that beams running across ceilings required special finishes, cornices, etc., and the amount saved on the engineering structure might be much less than the extra cost of architectural finishing. The adoption of uniform column sizes might be more economical ultimately, for the same reason. Again, deep and narrow beams were, generally speaking, most economical from an engineering point of view; but they did not conduce to efficient lighting and ventilating, and it might cost more to get these necessary properties than the amount saved on the skeleton structure.

In order to design economical reinforced concrete structures many factors had to be considered, some of which varied in all cases, but there were three fundamental points which influenced all structures in the same way, and these were: (1) The effect of beam section on economy; (2) the effect of percentage steel on economy; (3) the effect of layout or arrangement of beams, columns, etc., on economy.

In dealing with the first factor, the relative economies of singly reinforced T-beams and singly and doubly reinforced plain beams, as regarded the ratio of breadth to depth, were discussed. The meaning of the second and third factors being self-explanatory were not further explained.

The total cost of any reinforced concrete structure, whether a single slab, column, a whole floor, or a complete frame, would be the sum of the total costs of the three items —concrete, steel, and centering—and these, in their turn, would depend upon the unit costs. Now, these unit costs would vary for different parts of the one complex structure, but not for any single member; so that while a mathematical expression for a single member was possible, it would be impossible, owing to the very large number of variable quantities involved, to deduce a mathematical general expression for all classes of structure, simple and complex. Any attempt to deal with the subject of economy mathematically could only lead to ambiguity and vexation. It was, however, possible to deal with the subject by taking different arrangements, percentages, etc., and by calculating the cost of the various items, the required totals could be obtained by summation. That method appeared at first sight to be rather formidable, but by a suitable arrangement of the work it would be found that the difficulty is more apparent than real.

The conclusions might be summarized as follows:—

1. As regards beam section—

(a) Reinforced concrete T-beams, correctly designed, with the total depth three times the breadth of web, are more economical than any other section for all values of unit cost and loading.

(b) For plain beams, reinforced in any way whatever, the most economical ratio of depth to breadth is 3 for all values of unit cost and loading.

(c) For singly reinforced plain beams, the most economical reinforcement percentage runs from 1 to 1.2 for all values of unit cost and loading.

(d) For doubly reinforced plain beams the most economical reinforcement percentage is 1, with equal tension and compression steel, for all values of unit cost and loading.

(e) Plain beams doubly reinforced may be more economical than similar beams singly reinforced, the relative economies depending upon the values of unit cost and ratio of depth to breadth of section, but not to any appreciable extent upon the loading.

The foregoing conclusions were quite independent of any economies effected by adopting uniform sections throughout a design.

(2) As regards percentage of steel—

(f) For ordinary values of unit cost square columns, helically reinforced, are most economical of cost when the diameter of lateral is small, the pitch of lateral is 0.2 the breadth of core, and the percentage longitudinal steel is high

(g) Increased economy of cost will result from the use of longitudinal reinforcement having a lower yield point than ordinary mild steel, provided such material be cheaper than mild steel.

(h) The greatest economy of space is obtained by using large diameter laterals, pitched at 0.2 the breadth of core, and a high percentage of longitudinal reinforcement.

Summarizing conclusions drawn from layout, etc., he states:—

(i) A rational arrangement of slabs and beams supported by columns is more economical than slabs supported by beams only.

(j) A low-percentage slab reinforcement is more economical than a high percentage.

(k) A thin slab is more economical than a thick slab.

The British Columbia Electric Railway Company will spend nearly $200,000 in New Westminster this year. The new freight yards between Fourteenth and Sixteenth Streets, which will have a storage capacity for four hundred and fifty freight cars, will take $100,000, while $50,000 have been appropriated to new car barns. These barns, it is believed, will be the largest in Canada and will be capable of housing nearly fifty interurban cars. The clearing of the site is nearly completed and building will start shortly.

TRANSFORMER AND TESTING PLANT.

The following 60,000 volt testing plant has been designed and constructed by Messrs. Switchgear & Cowans, Limited, of Manchester, for the Union Cable Company:—

The current is taken from the local three-phase supply mains at 220 volts, and is transformed to 2,000 volts single-phase by the transformer shown on the right in Fig. 1. The single-phase current at 2,000 volts passes from the secondary terminals of this transformer to the primary terminals of the Cowan-Still regulating transformer (shown in the circular tank in the centre of the view, Fig. 1). The output of this regulating transformer at the secondary terminals is from zero to 2,000 volts. This feeds in turn the primary circuit of the high-tension transformer shown to the left-hand of the illustration, which gives out zero voltage to 60,000 volts, according as the hand-wheel of the Cowan-Still regulator is operated.

The plant has the advantage that there are no running parts, so that no dirt or dust is produced by its working. The control of the voltage on the high-tension transformer is gradual from zero to full volts, without any steps or jumps. For speed of manipulation the plant leaves nothing to be desired, as it is possible to pass from zero to full volts, or vice versa, in about ten seconds. If the test necessitates that the voltage should be applied suddenly, the article to be tested is connected to the bus-bars, the regulator turned until the correct testing voltage has been obtained, and then the switch shown on the extreme right in Fig. 1 is operated to switch off and switch on as many times as may be required.

The overall efficiency of testing sets of this type is high. In the case in point the alternative suggestion before the Union Cable Company consisted of a three-phase motor-generator taking the 220-volt supply at the motor side and driving a single-phase alternator, the latter being coupled

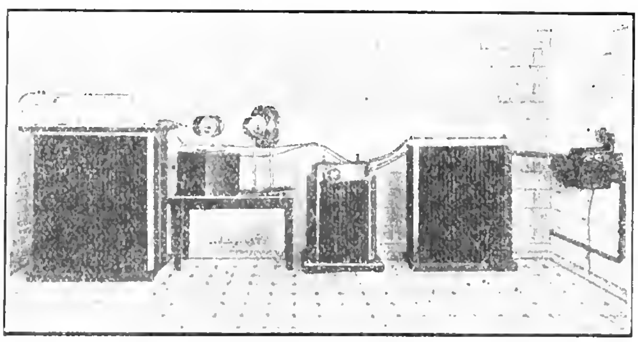

Fig. 1—Testing Plant.

directly to the primary of the high-tension transformer. With a set of this kind, provided with suitable regulators of the ordinary type, sufficient control of the high-pressure testing voltage can be obtained, but although in this case the existing supply at 220 volts three-phase was in favor of the motor-generator equipment, the overall efficiency of the transformer equipment was better. It is claimed that in cases where high-tension single-phase can be introduced directly to the regulating transformer, there is a very marked saving, both in capital cost and also in efficiency, by the use of the transformer equipment.

The capacity of the testing set illustrated is 50 kw. The transformers are made in all sizes, the smallest being of one kw., one of which has, we understand, been recently supplied to a colliery for testing purposes. Testing with a 1-kw. set is usually performed by the regulating transformer only. The makers supply this size of transformer in a circular steel case provided with a lid; the cable connections pass through bushes, and, when made, the lid is closed, and, if necessary, padlocked. The connections are single-phase. If three-phase current only is available, current is tapped off between two phases. The regulator is designed usually to raise the initial pressure to four times its value; thus any voltage may be applied for testing purposes up to four times the working pressure between phases.

Reverting to the larger type, as illustrated, the terminals of the H.T. transformer are arranged in the manner shown in the diagram (Fig. 2), and the connections shown in thick black lines are made by inserting flat copper links into clips. Testing may be performed at 10,000, 20,000, 30,000,

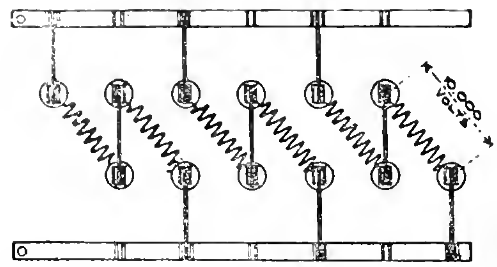

Fig. 2.—High-tension Couplings, Allowing for Combinations from 10,000 to 60,000 Volts.

40,000 or 60,000 volts, and a test may be taking place at 20,000 volts and another one at 40,000 volts simultaneously. For tests of moderate pressure, up to 10,000 volts, six tests may be proceeding simultaneously. At all voltages the operator has complete control by means of the regulating transformer.

The application of this transformer for testing purposes is rather inidental; its true application is for feeder regulation, for which purpose it is highly insulated, is inserted directly into the line of any given feeder, and boosts that feeder from zero to, say, 10 per cent. of the working voltage. The regulating transformer can also be designed to boost positively and negatively. For example, if it is desired to maintain a constant voltage of 6,000 at the secondary terminals of the transformer, a voltage variation on the feeder of between 5,700 and 6,300 may be successfully dealt with by a standard 10 per cent. transformer wound for boosting in both directions.

SASKATCHEWAN ELEVATORS.

According to the figures supplied by the Board of Grain Commissioners, two hundred and forty-three new grain elevators were erected in the province during 1912, giving an increased capacity of 7,064,000 bushels. This number includes those built by the Saskatchewan Co-operative Elevator Company. It will also be seen from the accompanying tables that Saskatchewan has an elevator capacity of over two million bushels more than Manitoba, Alberta and British Columbia combined.

The following table gives the number and total capacity of elevators and grain storage warehouses in Saskatchewan in each of the years 1912-1907:—

Year.	Number.	Total capacity.
1912	1,252	36,503,000
1911	1,000	29,439,000
1910	909	26,440,000
1909	842	24,279,000
1908	638	18,138,500
1907	516	14,621,500

EFFICIENCY OF CONDENSER AIR PUMPS.

In late years, jet air pumps and rotary (whirling) air pumps have been introduced for condenser service. The advantages of this type of pumps are well known, namely, their simplicity, the practical absence of attendance, and the ease with which repairs can be made by substituting a new outfit for the damaged one.

The introduction was facilitated by the shortcomings of the then existing types of reciprocating air pumps. These shortcomings consisted in complications such as mechanically operated valves, with the necessary valve gearing, large clearance and flash ports, the necessity for close adjustment on account of the small width of the flash ports, their sensitiveness for entrained water and the fact that at high vacuum the heat of compression warps the mechanically operated valve, and thereby makes further increase of vacuum impossible. Frequently these pumps were driven by steam cylinders with complicated Corliss valve gear.

Coupled with these features was the general lack of knowledge of the volumetric efficiency of such pumps. In contradistinction to the ease with which tests can be run on jet and whirling air pumps, tests on reciprocating pumps require more expensive installation and equipment.

The old law that improvement in one line produces improvement in a competing line, is true also in this case, and thus we find a new design of reciprocating air pump.

This air pump, which is illustrated by Fig. 1, has no mechanically operated valves on the air cylinder, but has instead automatic valves of the multi-ported plate type (Iverseen patent). There are no flash ports, and no large clearance spaces due to such flash ports. The valves need no attention and no oiling. They open and close at the right time independent of any adjustment.

These valves have been very successful on blowing engines and air compressors. In order to test this type of pump for reliability and economy, it was set up in the works of the Mesta Machine Company, at Pittsburg, and who are placing the pump on the market, and subjected to a thorough test by Prof. W. Trinks, of the Carnegie Institute of Technology. The test rigging is shown in Fig. 2. From left to right there will be noticed the bed plate of the air pump, then the steam cylinder and the air cylinder. The large vessel to the right is simply a tank for converting the pulsating suction of the air pump into a steady flow so that the actual quantity of air taken into the pump could be measured by a standard nozzle. This nozzle will be seen at the extreme right of the picture. Another nozzle was provided at the side of the tank away from the spectator and through this nozzle vapor could be admitted for the purpose of testing the pump under conditions existing in condenser practice. The usual precautions were taken to avoid leakage through the tank, and its joints, and to measure the very small amount of leakage which existed when the valves on the tank were closed. The steam passing through the steam cylinder was condensed at atmospheric pressure in a surface condenser located in the pit under the flywheel. The water resulting from condensing the steam was measured in barrels.

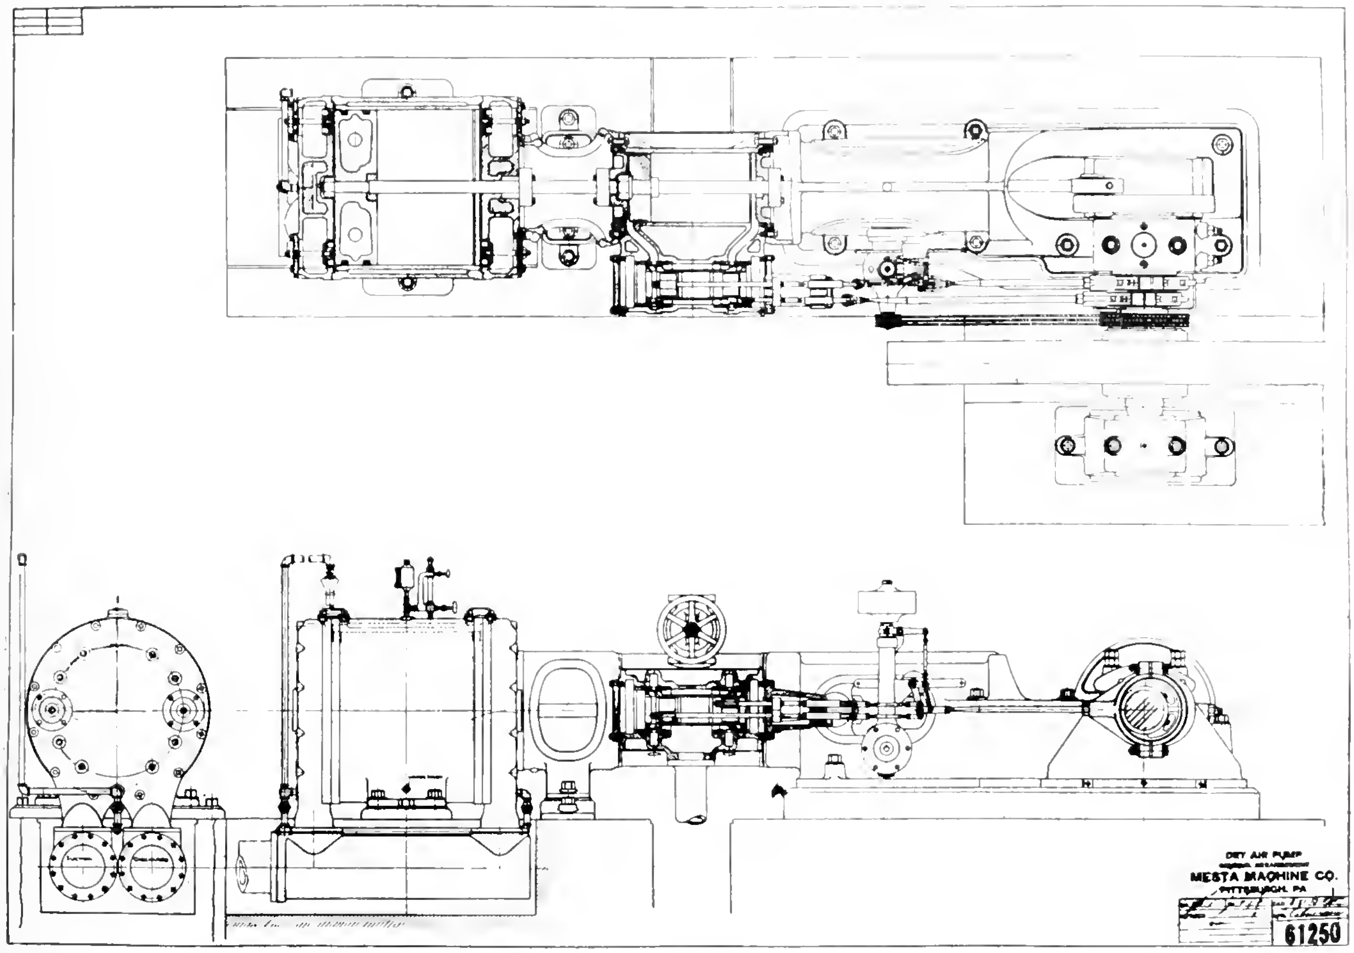

Fig. 1.

In work of this kind, it is not feasible to give the steam consumption per cubic foot of air pumped, because the steam consumption must necessarily vary with the vacuum, with the efficiency of the air pumped, and with the efficiency of the prime mover. It is much better to plot the power consumption of the air pump so as to separate the efficiency of the air pump from the efficiency of the prime mover. For this reason, the ratio of ideal work required for isothermal compression divided by actual work (including all friction work of engine) required, has been plotted against vacuum referred to 30-in. barometer. On the same sheet has been plotted the efficiency of the most advanced type of whirling air pump, as taken from tests published in reliable papers, also the efficiency of whirling air pumps of average type. These latter figures were taken from results furnished by the builders of such air pumps. The illustration shows that for any vacuum less than 29 inches of mercury, the single stage reciprocating air pump is superior to the whirling air pump, and that the difference is considerable for any vacuum less than 28½ inches of mercury. For vacuum above 29 inches, the single stage air pump drops rapidly in efficiency and becomes useless for higher vacuum than 29 1/10 inches. The Mesta Machine Company advises that they are at present building a compound air pump and will furnish test results of that pump in the near future.

The whirling air pumps are commonly driven by small steam turbines whose steam consumption per horse-power-hour is of necessity very high. When it is considered that the reciprocating air pump is driven by a fairly economical type of engine (whose steam consumption per horse-power-hour is approximately one-half of that of the small turbine) the difference in efficiency becomes still more pronounced.

It is not intended to convey the impression that the reciprocating air pump is always superior to the whirling air pump; on the contrary, it will pay in some places to use the whirling air pump in spite of its low efficiency, because exhaust steam is needed to heat the feed water.

On the other hand, the curves on Fig. 3 show conclusively that the reciprocating air pump of the style here described should be used wherever sufficient amount of exhaust steam for feed water heating is available from other sources.

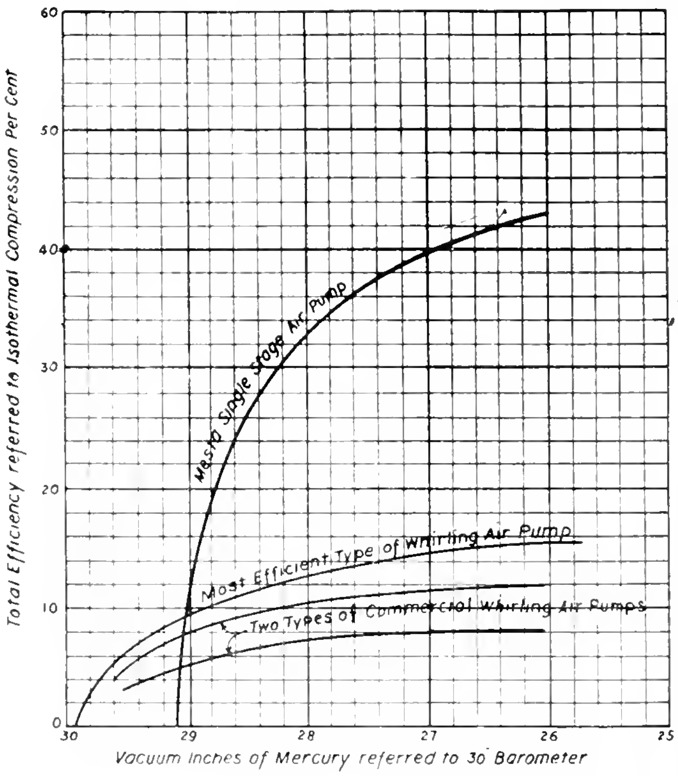

Fig. 3.—Test Showing Efficiency of Air Pumps for Condensers.

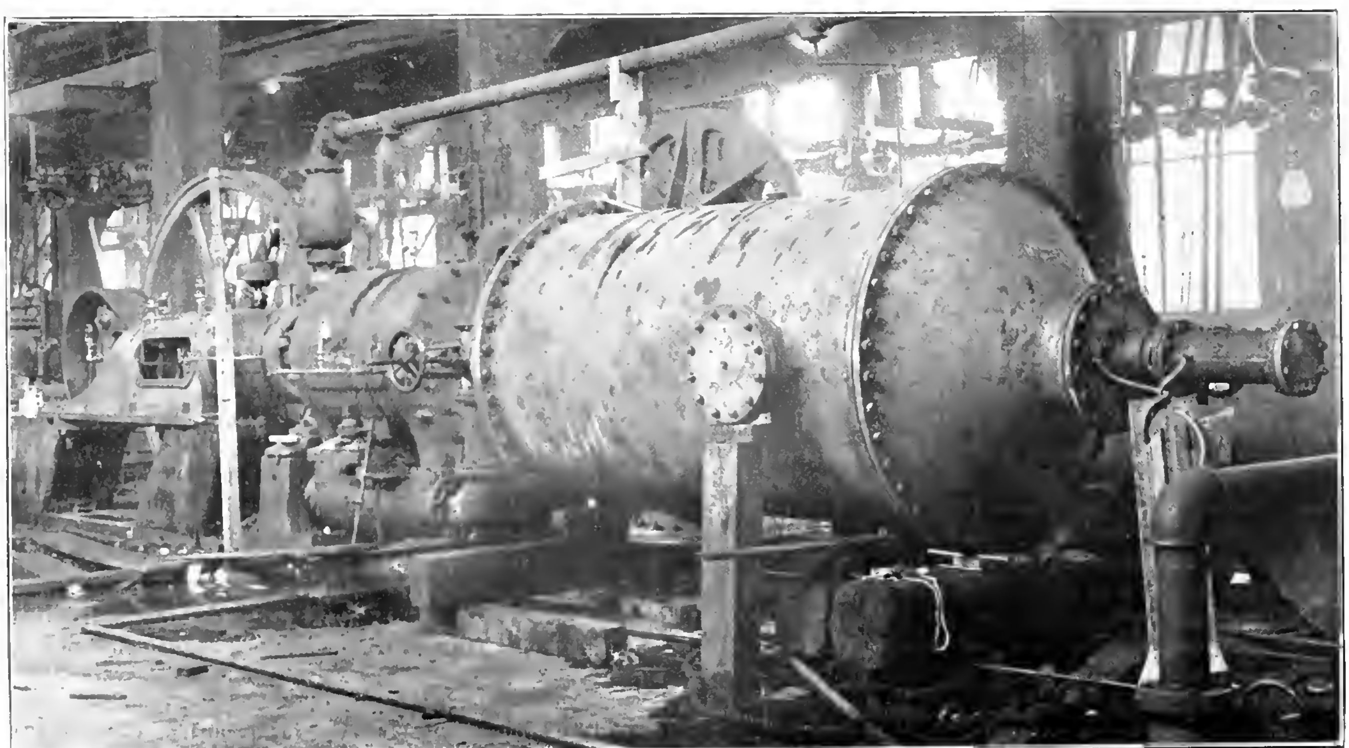

Fig. 2.—Testing Arrangements.

HIGHWAY BRIDGE OVER THE MIAMI RIVER AT ELIZABETHTOWN, OHIO, THAT RESISTED THE RECENT FLOOD.

This bridge is remarkable in being the longest simple-truss span in existence. It has a span of 586 feet between centres of end pins and surpasses in length by 36 feet the longest other span, which is one in the bridge crossing the Ohio River at Cincinnati, known as the Cincinnati and Covington railway and highway bridge.

On the site of the present new steel bridge, there had been for many years an old covered wooden bridge, known locally as "Lost Bridge." It consisted of three spans, 195 feet long each, supported on stone piers and abutments. The old piers were unusually heavy, and yet, notwithstanding this fact, the foundation beneath them was badly scoured, so much so that one had fallen several feet out of plumb at the top. The superstructure of the old wooden bridge was also rapidly failing, the spans showed excessive sag, a condition frequently developing in old wooden bridges before failure. In the summer or autumn of 1903 the superstructure of the old bridge was destroyed by fire, and the need of replacing it at once became apparent.

In selecting the most suitable type of bridge for replacing the old one, there were numerous important considerations. The rise and fall of the water in the Miami River is very uncertain. At flood seasons it rises rapidly, sometimes 20 feet or more in a few days. The greatest difference between high and low water is about 30 feet. At such times the last ten feet or more of rise is back water from the Ohio River. For this reason all bridges in this district are built at about the same elevation of 30 feet above low water of the Ohio River. The railroads and many of the highways are likewise built on banks at the same elevation, for at flood seasons the entire country around is liable to be covered with water.

At another river crossing, about a mile distant from Elizabethtown, the conditions had been met in previous years by building a suspension bridge of 500 feet clear span, spanning the entire width of the water course. The suspension bridge is quite an imposing structure and an ornament to the district, but is lacking in the more important requirement of rigidity. It has a clear roadway of 20 feet and the stone towers at either end are placed 36 feet apart, so the cables have a considerable cradle. It has, also, six sets of stay cables from the towers to the floor, and is braced laterally by three sets of rod guys at each end, fastened to stone blocks on the river bank, yet the passage of ordinary loads, such as farm wagons, causes excessive vibrations. In high, or even moderate winds, the swaying of the bridge is also considerable.

At New Baltimore, Ohio, in the same county, similar conditions had been overcome by building a single truss span 465 feet in length.

The railroads were also having difficulty with their bridges in the same region, and some such bridges were destroyed by having their piers undermined by the scour and wash of the uncertain currents and soil. At the time when the rebuilding of the Elizabethtown bridge was being considered, a railroad bridge in the vicinity was being strengthened and the piers protected at great expense, by having large quantities of broken stone and loose rock deposited around the piers and abutments. It was found, however, that notwithstanding the dumping in of many carloads of rock, and the strengthening of piers with additional concrete, the river piers were still in an uncertain condition and frequently exposed to the damaging influence of scour and the shifting of the channel.

For these reasons it was decided to avoid the use of river piers in rebuilding the bridge at Elizabethtown, and to bridge the entire waterway with a single span. Having thus decided on the use of a single span, approximating 600 feet in length, it then became necessary to select the most suitable type of bridge.

The suspension bridge described above is in some respects very desirable, but on account of its lack of stiffness was not seriously considered as a type for Elizabethtown. The underneath clearance would not permit the use of a deck arch of so long a span, and a through arch, such as those used at Bonn or Dusseldorf, or more recently at Bellows Falls, Vermont, are lacking in lateral stiffness. In through arches such as those mentioned above, it is necessary, in order to maintain the required clearance through the bridge, to omit top lateral bracing between the arch ribs for some considerable distance back from the springs. This is more serious than in truss bridges, where the end posts incline at an angle of 45 degrees or more with the horizontal. With the through arch the slope of the ribs is so gradual that a large part of the most effective lateral bracing between the ribs must necessarily be omitted.

Some forms of stiffened suspension bridge, and a cantilever design of 600 feet span between piers, with back stays similar to the back stays of a suspension bridge, were also considered. None of these forms were favored, chiefly because of their lack of stiffness. Of the alternate forms considered, the cantilever above referred to would doubtless have given the best results. It would leave the waterway entirely free of piers and would permit the use of a narrower roadway, by placing the trusses further apart at the shore, than at the end of the cantilever arms. It is interesting to note that a bridge of this type has since been built at Long Lake, N.Y.

After due consideration of various types, it was decided to use a through, pin connected, simple-truss bridge.

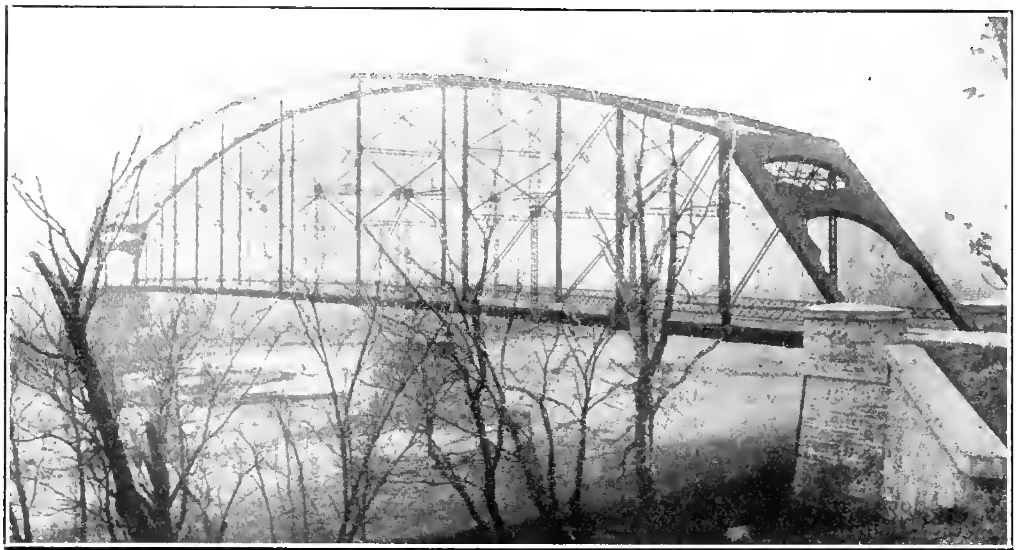
The foundation work consisted chiefly in repairing the old stone abutments by building up new material in reinforced concrete in front of the old stone work, carrying up the retaining walls and parapets, and rebuilding the bridge seats with lines of steel beams embedded in concrete.

The type of truss is the subdivided Pratt, with main panels 65 feet long. The depth of truss varies from 80 feet at the centre to 40 feet at the first panel point. The curve of the top chord is a parabola, in straight sections of two panel length. Stiff laterals and sway bracing are used throughout. This is a very essential feature of the design, and one upon which much of the stiffness of the bridge depends. Lateral and other light struts are built in box form, latticed on all four sides. The first panel of diagonals in the top lateral system are built in the same way. Each of the 32-feet-6-inch panels of the floor system are again subdivided by carrying an intermediate floor beam on two longitudinal beams, one at each side of the bridge. In addition to the benefit of economy in floor framing, the two side beams serve also as chords for the lower lateral system. The longitudinal and cross floor beams are of the same size, and diagonal laterals are rigidly connected by plates, which fasten to the bottom flanges of both cross and longitudinal beams. The floor joist consist of 6-inch steel beams, spaced 2 feet 6 inches apart, elevated on 9-inch beam corbels. On the steel joist is laid the 2½-inch oak flooring, spiked to six lines of 3 x 7 oak spiking pieces, with 60d nails. The wheel guards are 6 x 6-inch oak, beveled on the inner edge and elevated on 4 inch blocks, spaced 2 feet apart for drainage. The bridge was given an initial camber at the centre

of 3 feet. On each side of the roadway there is a neat railing, made of four angles latticed in box form. This railing lines up with the inner face of the web posts and fastens to them.

The two side lines of heavy floor stringers, which act also as wind truss chords, are rigidly attached by means of bottom bracket angles to the main truss posts. Such portions of the wind chord stresses as are not resisted by these longitudinal side beams, are transferred to the bottom chord eye bars, through these rigid connections.

in determining the stresses, was 2,900 pounds. This includes the weight of all steel and lumber, and 300 pounds per lineal foot for snow and ice. The snow load causes no vibration or impact and was therefore classed as dead load. The effect, however, on the web members of a partial snow load, was considered and provided for. Wet lumber was assumed to weigh seven pounds per foot board measure. Seven-tenths of the entire dead load was assumed as acting at points of the bottom chord, and the remaining three-tenths at the points of the top chord.



The Elizabethtown Bridge.

The cross beams, at the panel points, are suspended by two rod hangers 1½ inches in diameter each, from the bottom chord pins, and at the same time they are riveted to the bottom angles on the web posts. This gives a rigid beam connection and at the same time reduces the cost of erection. At one end of the bridge are sets of turned rollers, and at both ends the heavy side beams are connected to the shoe boxes, thereby transferring the wind strains as directly as possible to the masonry. The vertical posts are spliced at the joints of the lateral struts. The minimum thickness of metal used is one-quarter inch.

The metal throughout is medium steel of 60,000 to 68,000 pounds per square inch tensile strength, conforming to the Manufacturers' Standard Specifications.

The assumed dead load per lineal foot of bridge used

The assumed live load was 1,000 pounds per lineal foot of bridge, for the trusses, and for the floor and its supports 70 pounds per square foot of roadway, or a ten ton road roller or wagon. These loads are all in addition to the weight of snow and ice as described above.

The wind load was taken at 30 pounds per square foot of exposed surface.

After the completion of the bridge it was the intention to remove the two river piers, one of which was already leaning over and in danger of falling.

This bridge, which resisted the recent floods in Ohio practically without damage, was erected some years ago. Mr. H. G. Tyrrell, consulting engineer of Evanston, Ill., a graduate of Toronto University, was the chief engineer for the design and construction.

WATER SUPPLY AND SEWAGE DISPOSAL.

The town of Swift Current, Sask., has experienced no little inconvenience this winter owing to the Swift Current creek freezing solid to the bottom. The creek is the source of the town's water supply. Fortunately there was no serious fire in the town while the water shortage existed. Plans provide for a three days' reserve supply of water for the town, and the latter will, by forming an impounding reservoir, prevent any possibility of the source of supply failing on a future occasion. The town of Swift Current is very favorably situated for a gravity supply from a service reservoir, the ground to the south of the town rising to a sufficient elevation to give ample pressure for domestic services.

Plans and estimates for the waterworks are at present receiving the consideration of the Bureau, and if they are approved a by-law will be voted on by the ratepayers, which will include the following works to be executed this year:—

Reservoir	$20,000
Pumping and gravity main	34,500
Water extensions on north side of town	16,500

Plans were recently approved of by the commissioner of public health for a system of water supply, sewerage and sewage disposal for the town of Sutherland. The water supply will be obtained from the city of Saskatoon, the latter city pumping its water from the South Saskatchewan River, and treating it by a mechanical gravity filtration plant. The proposed site for the sewage disposal works is on the south bank of the Saskatchewan River at a point where ample fall is obtainable. Provision has been made for chlorinating the effluent before its discharge into the river.

GOVERNMENT INVESTIGATION OF ICE CONDITIONS IN THE GULF OF ST. LAWRENCE.

The Federal Government in arranging on the opening of navigation for a patrol service by the Canadian Government steamship Montcalm in Cabot Strait for purposes of ice research and present warning to ocean shipping of ice conditions is tackling in a commendable way the problem of removing from the St. Lawrence route and the public mind an element of doubt and danger which had always haunted those using it. The further recommendation by a committee appointed to investigate the present pilotage system in the Gulf of St. Lawrence, advising a radical change and abolition of present methods, is another step in the same direction.

As regards the research work, the Government has arranged that Prof. H. T. Barnes, of McGill University, with a staff of assistants, shall be on board and carry out further experiments and demonstrations with his microthermometer. Prof. Barnes and his studies of ice problems are becoming so well known in the world of science that it seems almost unnecessary to recall to readers what a boon to shipping Prof. Barnes, in perfecting and developing the microthermometer, has created. In theory it is a very simply designed apparatus. It consists of a coil of wire of approximately 125 ohms resistance enclosed in a metal bulb and placed just below the surface of the water at the side of the ship. This coil constitutes the resistance in one of the four arms of an ordinary Wheatstone bridge. Two of the remaining arms carry constant resistances, the third arm being variable. As the temperature of the water varies the resistance of this coil also varies, so that the temperature of the water is easily calculated from the resistance readings taken.

Last year tests were made with this instrument on the Royal Mail steamship Victorian and Canadian Government steamship Montcalm, and some extremely interesting results were obtained about the temperature conditions found in the immediate neighborhood of icebergs. In every case as an iceberg was approached the temperature increased almost uniformly to the extent of about a degree over a five-mile circle surrounding the iceberg. This rise in temperature was very marked on the microthermometer, and occurred without exception in every set of readings taken as the ship either approached or left a berg. Professor Barnes was satisfied his instrument would detect the presence of icebergs without fail. In view of the success of these experiments it is evident that much added safety would result from the general adoption by all steamships of the device. We hope the present summer's work will still further prove its practicability and utility in northern Canadian waters.

"ETHICS OF ENGINEERING."

Faculties of Applied Science and Engineering throughout the universities of the Dominion are now holding examinations that presage the arrival of several hundred young men after years of study and preparation at the point where they are expected to become engineers in reality and not merely in title. Under the circumstances it is not inappropriate to consider some of the problems of the ethics of the profession which all engineers are bound to have thrust upon them.

Used in a broad sense, an engineer is "one who utilizes the forces of nature in the service of man." Such a definition immediately involves in the word "service" questions of finance which, applicable to man, includes the engineers themselves. Moreover, it does not necessarily follow that in reducing financial remuneration due engineers from the completion of beneficial work that the balance of mankind is even infinitesimally or indirectly benefited. There must be some point at which, if remuneration to an important profession drops, mankind itself becomes the sufferer from deterioration in the type of its followers. In so far as the attractiveness and remuneration of work and working conditions in the engineering profession is allowed to drop below the attractiveness of other important professional occupations there may develop a regrettable tendency for brains and ability to shun engineering paths. There might well be a possible loss both to the engineeing profession and mankind as well.

Many people will uphold that engineers as a body might be said to go further towards overlooking questions of financial remuneration and surroundings affecting themselves than any other organization of their size and importance in the world. Protective organization may not previously have been needed, but with the enormous development and specialization seen in engineering of late years there are signs that some of the profession are not quite as content or satisfied with affairs as formerly. In his inaugural presidential address to the Society of Engineers, England, Mr. Arthur Valon said the development of engineering during the past twenty years had wrought a great change in the personnel of the profession. The requirements for modern engineering training, contrasted with those of twenty years ago, showed that a great increase had taken place in the number of engineers occupying more or less subordinate positions, for which technical competence was a greater recommendation than personal initiative.

Speaking of the organization of the profession, Mr. Valon said that the numerous engineering societies had confined their work almost exclusively to educational matters, and but little attempt had been made to use the corporate strength of the profession to improve the status of engineers. A cental organization for dealing with appointments would be not only a great convenience, but a source of strength to the profession, as it would then be possible to issue warnings against appointments carrying unsatisfactory conditions.

With regard to statutory registration, it was only right that those who had spent time, energy and money in qualifying as engineers should be in a better position than those who had not done so; but before registration could be enforced there were many obstacles to be surmounted, which could be overcome only if the profession were united in desiring statutory recognition, and took steps to present their views in the proper quarter through a suitable organization.

EDITORIAL COMMENT.

The monthly figures given out by the Department of Labor all go to corroborate the need and importance of the present "Safety First" movement amongst railway men. During the month of March, for instance, according to the record of the Department of Labor, 480 industrial accidents occurred, of which 93 were fatal and 387 resulted in serious injuries. The greatest number of fatal accidents occurred to employees in the steam railway service, and of the non-fatal accidents, 115 were steam railway employees. The question of "Safety First" was discussed before the recent meeting of the Canadian Railway Club by Mr. N. S. Dunlop, of the Canadian Pacific Railway. It is a comparatively young movement, and results can hardly be expected immediately, but it is sincerely to be hoped that official figures showing a decided lessening of mortality amongst railway men will soon be witness to the effectiveness of preaching "Safety First." It is the intention to publish in the next issue a portion of Mr. Dunlop's address to the Canadian Railway Club on this subject.

CITY IMPROVEMENT.

While in Montreal Mr. E. E. Culpin, secretary of the City Planning Association, of England, recently lectured to the Civic Improvement League. During his lecture Mr. Culpin stated that the people are recognizing that it is the duty of the city to not only make itself beautiful to look at, but, more important still, beautiful to live in. This means that not only is attention being given to providing pleasing views, artistic public buildings and beautiful parks and gardens, but that the movement is now getting down to the very unit of the city—the citizen. The housing problem is becoming recognized as the one demanding immediate settlement, and the first step toward solving that problem is to secure a comprehensive plan of city making. The systematic planning of cities is not new. There is in existence a plan, drawn 5,000 years before Christ, for a town designed as a dwelling-place for the army of workers engaged in the erection of one of the pyramids. In the flourishing days of Greece and Rome, cities were planned with artistic care, and coming to modern times we have the reconstruction of Paris under Napoleon the Third. Italy was the first country to pass legislation regulating city-planning, while a little later Sweden made it compulsory. Germany then adopted the idea and raised it to the dignity of a science, but it remained for England to humanize it by putting in the forefront the interests and the comfort of the citizen. Some cities have made the mistake of believing that the chief end of city planning is to provide a magnificent centre. The civic centre is a desirable thing, but it should be only the focus for a civic spirit which seeks to improve living conditions for all citizens. Some cities are now spending hundreds of thousands of dollars on civic centres, when the money might much more profitably be expended on better housing.

CANADIAN GENERAL ELECTRIC ABSORBS ALLIS-CHALMERS-BULLOCK.

The shareholders of the Allis-Chalmers-Bullock Company met last Monday and authorized the sale of their assets to the Canadian General Electric Company. The assets include an agreement with the Allis-Chalmers Company, of Milwaukee, which will give the Canadian General Electric Company the exclusive right to manufacture and sell in Canada the Allis-Chalmers lines. These include Corliss engines, gas engines, water wheels and machinery for saw mills, flour mills, mines and cement mills. Business will be conducted under the name of Canadian Allis-Chalmers, Limited, a charter having been applied for. Mr. Milne, manager of the Allis-Chalmers-Bullock Company, will continue as manager of the new company.

THE GRAND RIVER FLOOD CONTROL.

A preliminary report dealing with the possibility of improving the general regimen and local flow characteristics of the Grand River by means of storage and training works, has just been made to the Honorable Adam Beck, chairman of the Hydro-Electric Power Commission of Ontario by Mr. H. G. Acres, Hydraulic Engineer to the Commission. The following is the text of the report:

Through the progressive obliteration of physical influences governing natural control, the flood flow of the Grand River has for some years past been gradually increasing in volume and destructiveness.

Consequent upon this steady increase in flood discharge, the low-water flow has been as steadily decreasing, so that in addition to a large annual loss by flood damage, there has been a material loss through shrinkage in power capacity. The realization that these conditions would tend to become worse year by year, led a number of the interested municipalities to solicit the help of the provincial government in the matter of an investigation for the purpose of devising, if possible, a feasible remedy; such remedy to serve the joint purpose of ameliorating flood conditions and of increasing the power capacity of the stream under conditions of minimum flow.

During the fall of 1912 a reconnaissance survey was made of the Grand River watershed covering the main stream from Caledonia to headwaters; also of the larger tributaries including Whiteman's Creek, and the Nith, Speed and Conestoga Rivers from their confluence with the main stream to headwaters.

The main purpose of this reconnaissance was not to furnish definite data as to the possibility or method of flood control, but rather to eliminate from the problem all portions of the watershed possessing physical characteristics of such a nature as to make more detailed examination plainly unnecessary. With the scope of the investigation thus restricted, it remained to ascertain what locations, if any, merited examination as sites for storage reservoirs and regulating works. The following locations, having the desired characterictics in varying degree, were established:

1. A site between Paris and Glenmorris where by means of a 40 foot dam a storage area of about 1,000 acres would be created. There is also in this vicinity a possibility of controlling about 1,400 acres of storage by means of a 70 foot dam. In both instances the back-water damage would be large, and in the case of the 70 foot dam, would involve the drowning out of several buildings and a considerable length of bighway.

2. A site near the village of Blair where a 30 foot dam would create a storage area about 1,400 acres in extent. The flooded area in this case would be largely meadow land.

3. A site near the town of Elora where a 30 foot dam would create a storage area about 3,000 acres in extent, the back-water damage involving principally meadow land and river flats.

4. Two sites on the Conestoga River, one of which would have a storage area of about 1,200 acres with a 40 foot dam, and the other about 1,000 acres with a 30 foot dam. In the first case, the back-water damage would involve cultivated land and a number of buildings. In the second case, pasture land would be mainly involved.

5. Two sites on the Speed River, one of which would have a storage area of about 600 acres with a 30 foot dam, and the other about 800 acres with a 35 foot dam. The flooded land in both cases would be swamp and poor meadow land.

6. A site on the Nith River near Canning, whe[illegible]5 foot dam would control about 1,100 acres of stor[illegible] back-water damage would be heavy as a number of [illegible]ldings would be involved.

7. A site on Whiteman's Creek near Mount Vernon, where a 45 foot dam would control about 450 acres of storage. The topography of the dam-site in this case would allow the construction of a 60 foot dam, but the back water damage would be very largely increased.

While it is to be understood that the above figures are superficial approximations only, it seems reasonably certain that a system of storage basins as above described would have an aggregate impounding capacity of not less than five billion cubic feet, in which event some beneficial effect through flood control might be expected.

While the information now available seems to indicate that material benefit may be derived from the construction of storage works, the extent of this benefit and the construction cost cannot be even approximately estimated without the help of instrumental surveys and comprehensive hydrographic study.

For the past eight months gauging stations have been maintained on the Grand River, at Brantford, Glenmorris, Blair and Elora. The stations have been so located as to provide information in connection with the characteristics of the main tributaries, and discharge measurements have been made periodically at each station. These measurements, besides recording the flow characteristics of the river under natural conditions and at different seasons, will provide the necessary data for forecasting the behavior of the river under future conditions of regulated flow.

The surveys necessary will involve,—

1. Instrumental determination of channel slope.

2. Detailed instrumental surveys of sites for proposed dams.

3. Surveys of storage basins to establish flood contours, and to determine the maximum possible or permissible limit of back-water.

The data derived from these surveys will provide the necessary information as to the two governing factors of artificial regulation; namely, the obtainable volume of storage capacity, and the extent of back-water damage. If this information proves that material benefit may be derived from the construction of storage works, the next step will be the exploration of foundation material by means of borings and test-pits, after which detailed construction plans will be prepared with estimates of cost.

It may here be mentioned that throughout the Grand River watershed, with the possible exception of that of the Speed River, the topographical features are unfavorable as affecting the height and length of the necessary dams, and the geological features are unfavorable as affecting their foundations. It is, therefore, certain that the creation of storage reservoirs of adequate capacity will entail a large capital expenditure. This expenditure will also be unfavorably influenced by the necessity of providing large spillway and sluice capacity for the safe passage of flood discharge.

Apart from conservation, another important element of flood control is the handling of back-water and the prevention of riparian damage due to erosion. The proper study of the problem under consideration will, therefore, necessitate the examination and survey of restricted channel sections, and of localities favorable to the formation of ice-jams; also a study of back-water effect due to existing dams.

With this information available it will be possible to determine to what extent, if any, flood damage can be reduced by means of channel improvement and the construction of training works.

The final phase of the investigation will be a careful examination of the more remote portions of the watershed to ascertain whether natural run-off conditions will be materially influenced by the permanent retention of existing swamp area, and furthermore, if any benefit might be gained by allowing areas now drained and reclaimed to lapse into their natural state.

In view of the important interests involved, and the practical certainty of a continuous annual increase in the extent of flood damage in the Grand River Valley, there can be no question as to the necessity of an investigation to determine the means by which this abnormal condition can be remedied or ameliorated.

As the solution of this problem will depend primarily upon data collected in the field, and as the investigation so far made seems to indicate that appreciable benefit is to be derived from the works projected, it is recommended that surveys be carried out along the lines above described, and with the least possible delay.

In conclusion, it is important to note that any experience obtained, or evidence of benefit derived from the carrying out of a flood control scheme on the Grand River, could be advantageously applied to several other streams in the Southwestern peninsula which suffer from lack of natural control. Among the most important of these streams are Thames, the Maitland and the Saugeen.

A NEW SPECIFICATION FOR SULPHATE CONTENT IN PORTLAND CEMENT.

A proposed new standard specification for the allowable SO_3 content in Portland cement was recently presented to the International Association for Testing Materials by the German Portland Cement Manufacturers' Association. The substance of the suggestion was as follows:—

Sulphates are found to some extent in all Portland cement, their presence being due, in part, to the raw materials and the fuel used in the manufacture, and partly also to the admixture of crude gypsum (hydrated calcium sulphate) during the grinding process. In a formal analysis of a Portland cement, the quantity of sulphates present is always stated in terms of sulphur trioxide or anhydrous sulphuric acid (SO_3).

The small quantities of SO_3 occurring in normal Portland cement are quite uninjurious to its practical application; and it is only when the amount exceeds a certain limit that during storage under water, a supplementary expansion —which may sometimes be dangerous—occurs in the hardened cement, owing to the formation of calcium-aluminum sulphate.

The permissible amount of SO_3 in standard specifications varies from 3 per cent. to 1.2 per cent., depending upon use in fresh or salt water. After an extensive series of tests, a universal percentage of 2.5 per cent. was strongly recommended for all cases, in view of the fact that it has been shown that the presence of SO_3 is not a vital agent in the deterioration of concrete exposed to sea water, but that this deterioration is due to the penetration of the magnesium sulphate of the sea water into the porous cement mortar. Obviously the way to remedy this is to obtain as compact a mortar as possible in the construction.

An interesting series of comparative experiments has been started by the Royal Laboratory for Testing Materials, Gross Lichterfelde, at the Island of Lylt in the North Sea. These tests are to continue over a period of ten years, and were started in 1907, the materials used being a Portland cement, S, containing 1.19 per cent. of SO_3, and a second Portland cement, B, with 0.57 per cent. Both cements were also tested with their SO_3 content raised to 2.5 per cent. by the addition of crude gypsum.

In considering the tensile values after hardening for one year, it appears that these values are lower throughout in sea water than in fresh water and the open air; and that, in spite of the low percentage of SO_3, cement B behaves less favorably than cement S in sea water. In both cases the raising of the SO_3 content to 2.5 per cent. by the addition of gypsum increased the tensile strength, both in fresh water and in sea water, with the exception of the mixture 1:4 of cement S. This mixture gave a slightly lower value in sea water; but the accuracy of this determination has yet to be confirmed at a later stage of hardening. The results of the tensile tests after one year's hardening show that the presence of even 2.5 per cent. of SO_3 in cement does not have any injurious influence during hardening in sea water.

The concrete blocks made from cement B showed at the end of 1½ years' hardening in sea water (autumn, 1909) such an amount of attrition that the fragments of granite were exposed. The blocks from the same cement with the SO_3 content increased to 2.5 per cent. behaved somewhat better. On the other hand, all the blocks made from cement S had remained in perfect condition. This observation was confirmed in general by the second inspection during the following year, which showed that the cement B, which was alleged to be particularly suitable for marine structures, turned out much worse than the cement S with the higher SO_3 content.

The same conclusion also resulted from the contemporaneous examinations of the plates set up in the mole at the harbor of Munkmarsch. The plates mixed in the proportions 1:2 and 1:4 of cement B exhibited concentric cracks, even at the first inspection, and many of them were burst across the middle: whereas the corresponding plates from cement S were perfect. It should also be noted that the plates made from cement B after raising its SO_3 content to 2.5 per cent. showed less extensive cracking than those made of the cement in its original conditions, i.e., with only 0.57 per cent. of SO_3.

After about three years' exposure of the plates to the influence of sea water, the chemical examination of the plates failed to reveal more than slight alterations due to sea water, in the case of the cement with the higher SO_3 content, whether in its original condition or after enrichment. The cement lower in SO_3 and used in its original condition, was found to have sustained extensive chemical changes under the action of sea water, though only to a smaller extent when enriched to 2.5 per cent. From these results it follows indubitably that the presence of up to 2.5 per cent. of SO_3 in Portland cement produces no injurious effects of any kind, whether in sea water or fresh water.

Moreover, the favorable experience that has everywhere been gained in marine construction works with sements of this kind, namely, containing a higher percentage of SO_3 than is prescribed in countries which issue special specifications for such works, demonstrates that the higher SO_3 content of the cements in question has not led to any injurious effects in practice, provided the cement has been properly used. It is therefore recommended that a uniform permissible maximum limit of SO_3,—namely, 2.5 per cent.—be generally adopted in specifications for Portland cement, whatever may be the purpose for which the cement is intended to be used.

THE MITTENWALD AND RJUKAN RAILWAYS.

A description of the above two single phase railways appeared recently in the February number of The Electrical Review. With the present day tendency towards electric railway construction in Canada, there is no doubt many of our readers will find the abstract of the article we publish interesting.

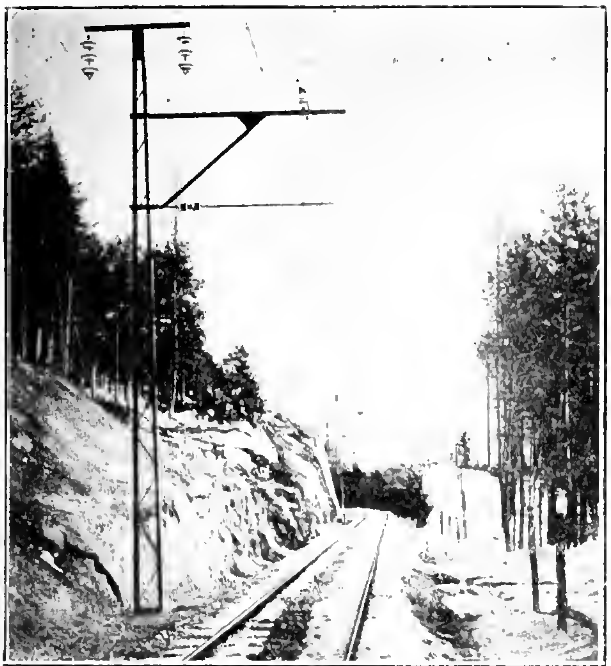

Fig. 1.—Mittenwald Railway, Showing Power Transmission Line.

The Mittenwald Electric Railway.—This railway system is sub-divided into four lines; the eastern line from Innsbruck to Scharnitz, 33 km. long, is frequently referred to as the Karwendel Railway, and, like the western line, 32 km. long, from Reutte to Griessen, passes through Austrian territory; between these lines comes the Scharnitz-Griessen section, which runs through Bavaria and has a length of about 40 km. This curious inter-connection of the sections lying in different countries is, of course, emphasized in the electrical equipment and the arrangement of the service.

On the Austrian sections there are 18 tunnels with a total length of 4,305 metres, one of which alone is 1,787 metres long. In addition there are numerous viaducts and bridges.

The constructional difficulties formed one of the reasons for the selection of electric traction. This, in fact, allowed the railway track to be better adapted to the nature of the ground and permitted a gradient of 36.4 per mille to be used on a large scale; the railway reaches a height of 1,185 metres above sea level at Seefeld, so that in a distance of 21.2 km. a difference of 600 metres has to be overcome. The adoption of steam traction would have necessitated the lengthening of the line by at least 4 km. just at the most difficult part, and the saving effected amounted to more than the total cost of the electrical equipment. Another factor making electric traction more economical is the cheap water power, the Tyrol occupying a still more unfavorable geographical position as regards coal supply than the adjoining country of Bavaria.

The Mittenwald Railway possesses a power station of its own, which is situated about 6 km. to the south of Innsbruck in the vicinity of the Sill Works, and utilizes the power of the Ruetzbach, a river close to the Sill.

In the Ruetz Works two 4,000 h.p. Voith-Pelton turbines have been installed for the time being, which are direct-coupled to single-phase generators with continuous outputs of 3,000 k.v.a. and maximum outputs of 4,500 k.v.a. The turbines and generators have been designed with due regard to the special conditions involved in railway operation, so that the plant cannot be endangered by heavy short-circuits or sudden alterations of load. The generators, which ran at a speed of 300 r.p.m., have six poles corresponding to the frequency of 15 cycles per second, which entails a somewhat higher cost as compared with the four-pole type, but enables the pole cores to be fixed with absolute rigidity to the rotor hub. The generators are wound for a pressure of 3,000 volts, and are self-ventilated, the magnet wheel being fitted with fan blades, and the stator enclosed by covers.

On entering the power station, one is struck by the perfectly noiseless running of the generators. The energy from each generator is led to a transformer which raises the pressure to 50,000 volts; from the point of view of the switchgear, each generator forms a separate unit with its transformer. As there are, therefore, no bus-bars or switches for 3,000 volts, extreme simplicity in switching operations is ensured.

Each transformer has the same maximum output as the generator, the continuous rating, however, is 1,800 k.v.a. The transformers are of the core type with disk windings and have oil and water cooling. The core with its windings is 23 tons in weight. Each transformer is placed in a separate fireproof compartment provided with an effective air circulation; the 50,000-volt switchgear is also enclosed in concrete cells so arranged that the switchroom, in the event of a breakdown, may be entered from two sides with-

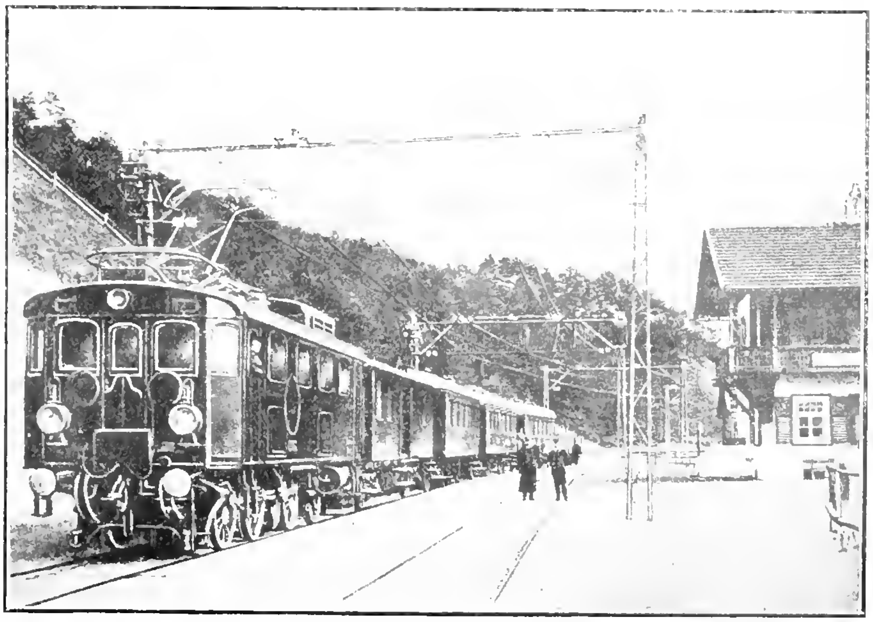

Fig. 2.—Locomotive and Train.

out danger. Switches are only provided on the 50,000-volt side; for the transmission line these switches are doubled.

All switches have electromagnetic remote control operated from the switchboard in the engine-room; they are fitted with automatic overload releases which can be adjusted for a time limit and are also arranged for hand operation. Lightning arresters, excess pressure discharges and choking coils for checking short-circuits are provided.

The energy generated at the power station is carried by a 50,000-volt line to two transformer stations where it is stepped down to the contact line pressure of 15,000 volts.

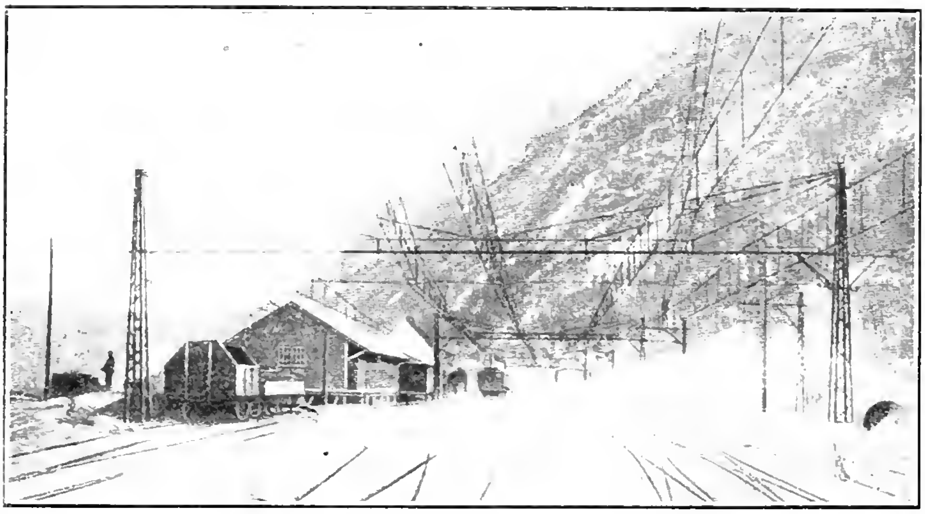

Fig. 3.—Arrangement Contact Line; Rjukan Railway.

The transformer stations, which will also supply current to the Bavarian line pending the completion of the Walschensee Works, are situated at Reith, 19 km. from the Eastern, and at Schanz, 3.3 km. from the Western boundary of Austria.

The transmission line, which is carried mainly on the poles for the overhead contact line, consists of two wires, each having a section of 35 sq. mm. Only the connection between the power station and the railway track (about 6 km. in length) is carried on a separate line of poles.

The first important section of the 50,000-volt line is situated in a desolate district, which is difficult of access in winter; increased care was, therefore, required in its design and construction. On this account, the line in this part consists of three wires, two of which are usually in service, the third serving as reserve to replace a defective wire.

As a protection against atmospheric discharges, a copper earthing wire is mounted above the h.t. line on the tops of the poles, and is carefully earthed to the depth of ground water at each pole. Lattice poles are employed exclusively for carrying the line, and are erected at distances of 80 metres apart; every fourth or six pole will stand firm, even when the line breaks on one side, the intermediate poles being flexible. The 50,000-volt line, for the section from 8.8 km. to 16.3 km. on the Innsbruck-Scharnitz line, has also been erected on a special row of poles, the number and length of tunnels in this section being too considerable for the line to be laid out on the contact line supports.

On account of the transmission pressure of 50,000 volts, which is rather high for Continental practice, special care had to be taken in choosing a suitable type of insulator, as far at least as its mechanical strength was concerned. The overhead line follows a series of sharp curves, and the poles have to stand the jerks produced by the swift motion of the current collectors. Investigation showed that only chain-ling (disk) insulators would stand this heavy stress, no part of these insulators being exposed to traction or inflection strains. The type of insulator ultimately developed by the A.E.G.-Union Co. possesses a breaking strength of 7,800 to 8,000 kg. with a weight of only 2.8 kg. Moreover, it also possesses excellent insulating qualities.

An essential difference between this insulator and those used by American engineers is that the channels are not of circular cross-section and instead of a wire rope exposed to rusting, steel bands applied throughout their width on the porcelain (so as not to injure the enamel) are used to fix it. After fitting the insulators in position, the channels are filled in, thus preventing any water from entering and freezing within the insulator. Another distinctive feature is the flexible armature of the insulator which absorbs all shocks, thus preventing any damage to the enamel.

Chain suspensions, without any automatic tightening devices, are used for the contact wire, which is exclusively carried by lattice poles.

The rolling stock of the Mittenwald railway at present comprises nine locomotives, each of a normal output of 800 h.p. As previously mentioned, the maximum gradient of 36.4 per mile is found extensively on this railway; each locomotive will haul over this gradient a gross train weight of 124 tons at about 30 km. per hour, which corresponds to a tractive effort of about 7,500 kg. What this performance really means will be gathered from the fact that the locomotives during several months' experimental work on the Dessau-Bitterfeld Railway hauled goods trains of 1,100 tons in schedule time over the level track.

Each locomotive, inclusive of the driver and the oil and sanding tanks has a weight of 53 tons in working order.

The current is taken off the overhead wire by two bow collectors each having two sliding sections, and is conducted by a bare high-tension wire arranged above the roof, to a lightning arrester choking coil, and thence into a transformer room where the line is connected up to the h.t. oil switch. The latter has a quadruple break, and includes an extra resistance for reducing any strain produced in switching in the transformer. From the front driver's platform the oil switch is operated directly by the switch lever; from the rear platform it is switched out by a button fed through a series resistance from the controller coil, while a lever system is used for switching in. Between the lightning arrester coil and the oil switch there is inserted a grounding switch operated automatically as soon as the protective cap of the oil switch is removed.

The driving motor is a 12-pole single-phase commutator machine of 800 h.p. normal output, at a speed of 30 km. per hour. It is designed on the A.E.G. system, in accordance with which (contrary to the directly-fed pure series motors), the current in the armature is induced by transformer effects. The rotor winding is, in fact, closed by short-circuiting brushes, thus obtaining the secondary winding of a transformer, the primary winding of which is the field winding of the stator.

Excitation is effected from the rotor, current being supplied to the armature through another pair of brushes from a special exciter transformer connected up in series with

the stator winding. The armature slots are nearly closed, and are arranged slanting to the direction of the axis.

Regulation of the motor speed is effected by altering the supply pressure by means of contractor switches, which are connected up to tappings of the power and exciter transformers, and are actuated by the controlling current. The controlling current is derived from a special (300-volt) coil of the power transformer.

Each of the two controllers has two separate switch-drums, one of which operates the contactor switch of the power transformer, and serves to regulate the power consumption, whereas the other operates the exciter switches, thus controlling excitation. The exciter drum moves the reverser into its proper position in a preliminary stage to "forward" and "backward" respectively. Each of the two switch-drums is entirely self-contained, so that any position of one can be combined with any position of the other, thus obtaining a minimum k.v.a. consumption for each speed of the motor.

Fig. 4.—Tunnel; Rjukan Railway.

The contactor switches are electrically interlocked by auxiliary contacts so that the working of any one group interrupts all the remaining switch coils.

Provision is made for two locomotives to be joined up in multiple connection for hauling train weights of up to 250 tons. This arrangement allows both locomotives to be controlled by a single driver. The conductors for the motor-compressor and the lighting and heating of the locomotives are connected up to the same switchboard with the controller circuit and are fitted with hand switches. All these circuits are fed from the 300-volt controller coil, which has a 19-volt tapping for the lighting circuit. The motor-compressor, which supplies compressed-air for the Westinghouse and Henry brakes as well as for actuating the current collectors, sanders and signal whistles, is thrown into and out of circuit automatically.

Each of the radiators provided for heating the locomotives has an output of 1 kw. Heating sockets are provided at the ends of the locomotives for heating the train, which are connected up to the cars by coupling cables.

The Rjukan Railway.—This is the first standard gauge electric railway in the South of Norway to be installed on the single-phase system. It comprises two sections separated by the Tinn Lake, the northern section (from Saaheim to the Tinn Lake) being the Vestfjorddals Railway, 16 km. in length, and the southern section, about 30 km. long, the Tinnos Railway, running from Tinnoset to Notodden, along the Hitterdals Lake. A ferry across the Tinn Lake will connect the two sections.

The Rjukan Railway is mainly intended for the transport of artificial saltpetre manufactured in Saaheim, to Notodden. Trains with a maximum trailer weight of 290 tons are drawn on the section from Notodden to Lilleherred, which has a constant gradient of about 2.7 per cent. by two locomotives, and on the remaining sections by a single locomotive.

The rolling stock comprises three four-axle, and two two-axle locomotives. The former have two bogie trucks, and are fitted with four alternating-current motors, each having an hourly rating of 125 h.p., and weighing approximately 46 tons. The two-axle locomotives have two motors of the same size, and weigh about 23 tons. The locomotives are constructed for a line pressure of 10,000 to 11,000 volts, 15 to 16 cycles, and are designed for contactor control.

The track equipment consists of a single catenary suspension overhead contact line, the distance between the poles being about 60 metres. On some sections bracket suspension is used, while on others cross-suspension is employed. We illustrate the form of suspension adopted for the overhead line in a tunnel.

The power supply is derived from a separate converter station for each section of the line, only 50 cycles, three-phase current at a pressure of 10,000 to 11,000 volts being available; the converter station feeding the northern section is situated at Vestfjorddalen, and contains two converter sets. Each of these comprises a three-phase transformer which steps down the pressure from 10,000 to 5,000 volts, and feeds an asynchronous motor driving an alternating-current generator with an output of 400 k.v.a., which supplies the line. The converter station receives its energy from the Rjukan power station, which is about 5 km. distant.

The southern section is fed from the Svaelgfos converter station, which is situated in the same building as the power station and consists of three converter sets similar to those above described.

MUNICIPAL OWNERSHIP SUCCEEDS.

Municipal ownership of public utilities in Edmonton resulted in a net surplus of more than $60,000 during the twelve months ended October 31st, 1912, according to the annual report of City Auditor Richardson, submitted to the council at its last meeting. The report shows the city has assets valued at $15,982,205, the assets in cash totalling $642,095. There was a net deficit of $10,033, due to over expenditures. There is $2,021,162 in unexpended debenture funds on hand, against which there is an allowance of $600,000 for the city's share of street-paving and sewer construction. Debentures authorized and unsold amount to $1,267,260. The principal surpluses for the year are given as follows: Electric light and power, $85,656.75; power house, $13,311.60; telephone department, $4,324.63. The deficits, largely as the result of over-expenditures for construction and betterment, are: Street railway, $32,549; water department, $3,064; stores and works department, $8,618.

ADVISORY ROADS COMMISSION FOR NEW YORK STATE.

The following individual report of Mr. Eugene W. Stern, consulting engineer, Park Avenue and 41st Street, New York, made to the governor of New York State, on March 31st last, will be of interest to members of the engineering profession. We present herewith the full text of the report:—

The Advisory Commission on Roads was appointed by you on February 21st, to report to you on the following matters in connection with the building of highways in the State of New York, namely:

(1) To advise as to the proper organization and administration of the Department of Highways.

(2) To assist in the selection of a Commissioner of Highways.

(3) To gather information and make recommendations regarding the construction and maintenance of highways.

(4) To make such other recommendations as we may deem desirable, affecting the construction of highways in New York.

After carefully considering the report of the majority of the members, I find that it does not express with sufficient clearness and force, my views on some of these matters, and I, therefore, report to you as follows:—

Organization and Administration of the Department of Highways.—It is a prevalent idea with the public that the construction and maintenance of roads is a very simple matter requiring only ordinary business ability; whereas the facts are that in no department of public works is there greater opportunity for the exercise of sound engineering principles, technical knowledge of the subject, and true economy than in the building and maintenance of roads. A very great deal of money is being wasted every year by the road departments of many of our States in ignorant and useless experimentation on road materials, and methods that have been tried out and long ago abandoned by engineers experienced in this kind of work.

Highways in New York State will never be properly and economically constructed and maintained unless a thoroughly efficient engineering department be organized in connection therewith.

The Murtaugh bill, reorganizing the Department of Highways, which has just become law, unfortunately has grave defects, both in the entire scheme of organization, and in the small salaries attached to the principal positions, which defects, unless corrected, would seriously hamper any honest endeavor to thoroughly organize the department on an efficient basis.

My criticisms of the existing law are as follows:—

The commissioner is not required to be a civil engineer, nor one who has had experience in the construction of Engineering works, nor in the organization of engineering departments. The law would permit a layman to fill this very responsible position. If a layman were chosen, the engineering organization is not properly planned to be efficient, nor to attract to it the right kind of men. There should be under the commissioner a chief engineer of the highway department who should be directly responsible to the commissioner for all the engineering work and, therefore, should have full charge and responsibility in the preparing of plans and specifications, execution of the contracts, and of the carrying out of the work, likewise of the maintenance of all roads which come under the jurisdiction of the department.

The chief engineer should have the right to select his staff, consisting of three assistant engineers and nine division engineers, subject to the approval of the commissioner.

In such an organization, the commissioner would be able to hold the chief engineer entirely responsible, and the latter could not then complain about the division of responsibilities which the law permits in which the chief deputy is really no more than an engineering advisor to the commissioner, and has not any real responsibility or authority in the actual execution of the work, having absolutely no control over the division engineers, who are in actual charge of construction, nor over the second and third deputies, who have entire charge of the maintenance and repairs of all roads.

The bill as framed is not sufficiently exacting as regards the qualifications necessary for the so-called deputies, and limits the selection from among those who have had practical experience in construction and maintenance of highways. The bill is very weak in the use of these qualifications, which would permit a man who had been in such a position as foreman over a gang of laborers employed on road work to become a deputy, with all the great and highly important responsibilities which attach to the office. Furthermore, it would limit the field of selection to a small body of men. I would recommend that railroad engineers be eligible for appointment, as the experience in grading, construction of bridges, foundations, drainage, etc., gained in railroad construction is applicable to the similar problems met with in highway construction, and a thorough knowledge of organization and of the handling of men, and of business methods, a thorough practical training in construction, and zeal and efficiency, are among the qualifications of a successful chief engineer of an important railroad. The only qualification he might be lacking in would be experience in the proper surfaces for highways, but given the power to obtain advice from consulting engineers who have had special experience on this subject, it is reasonable to suppose that a competent chief engineer from one of our prominent railroads might be an ideal selection.

The compensation for the heads is altogether inadequate to attract the proper kind of men to this department. The commissioner should receive a salary of about $15,000 a year, the chief engineer of about $12,000 a year, and each of the assistant engineers, $6,000 a year. This increase over the salaries allowed in the Murtaugh bill, amounting in all to only $19,000 a year, ought to enable the State to obtain the services of men who are eminently qualified to fill such very responsible positions.

The law requires that inspectors of construction shall be selected from residents in the country in which the highway constructed or improved is located. While preference should be given to residents, we do not believe that this should be mandatory, as very often the appointment of non-residents might be found desirable or necessary, and be decidedly better for the efficiency of the service.

The chief engineer, the three assistant engineers, and the nine division engineers should not come under civil service requirements, as these men should form part of the official family of the commissioner, and be removable by him at any time for the good of the service.

Selection of a Highway Commissioner.—The selection of a proper person for the office of commissioner is most important. No matter how good the scheme of the reorganization of the department of highways may be, unless a wise selecion for the position be made, radical reform will not be effected.

Instead of naming particular individuals for this place, it would seem to me to be more important that the kind of man who would best fill such a very responsible position be indicated.

The commissioner should be a man of such high character and standing as to command the respect and confidence of the public at large. He should be of proven executive ability, with a thorough knowledge of how to organize such a department, and be chosen from the engineering profession if possible, otherwise he should be one who has had to do with the construction of engineering works.

Types of Roads.—The particular kind of a road to use in a certain locality is a problem which depends for its proper solution on a number of important factors, such as the kind and amount of traffic, the sub-soil, the climatic conditions, the cost of construction and maintenance, and the amount of money available for construction and maintenance. It would be entirely out of place, therefore, to recommend any particular types of roads, beyond calling attention to the fact that there are two fundamental requirements which are accepted as axiomatic by all who are authorities in road building, namely, that in all cases there should be perfect sub-drainage and a rigid foundation. There is no need for extensive experimentation in the near future on the part of the State of New York as to what kind of roads to build, for so many methods have been tried both at home and abroad that intelligent investigation of what has been already done would be sufficient to indicate what types of roads and road surfaces should be eliminated from consideration, and what types are best suited for particular localities.

It will doubtless become advisable from time to time to experiment with new types, but this may be done on a small and inexpensive scale. A short stretch, say, of a few hundred feet, will give just as valuable data, as regards durability, etc., if careful and intelligent observations are made, as many miles.

In connection with this problem, it is important that we recognize the fact that the difficulty of providing durable roads has been greatly augmented by the introduction of automobile traffic; the wear and tear resulting in their use being much greater than from horse vehicles, and that we must make up our mind to make much more durable types of roads than we have been accustomed to in the past.

There can be no doubt but that the rapidly moving automobile and auto truck have come to stay. This method of transportation is yet in its infancy, and before another generation, if proper roads shall have been provided to take care of it, the economic benefit to the community, resulting from their use, will be of great value.

Another important consideration which should not be lost sight of is the fact that the money to construct the new roads in this State is raised by bond issues, maturing in fifty years from the date of issue. It would be manifestly unfair, therefore, to future generations, to construct roads with this money that last only a few years, if more durable types requiring less annual expenditure for maintenance are economically practicable.

Maintenance.—The proper maintenance and repair of existing roads is just as important as the construction of new ones. England, France and some other countries of Europe, are far ahead of us in the thoroughness and efficiency with which they keep up their roads.

It is most important that the Department of Highways should be thoroughly organized for this purpose, so that repairs may be promptly, economically and efficiently made, for by promptly repairing small defects, not only is the road made better for constant service, but the cost of maintenance is decreased.

The amount allowed in the budget for maintenance should be sufficient to avoid any delays in making immediate repairs.

Additional Recommendations.—In addition to the foregoing, I make the following recommendations on matters not yet touched upon:

Existing contracts for roads which are undesirable should not be executed, but cancelled wherever possible.

New contracts should not be let until the commissioner shall have been able to thoroughly organize his department, and investigate the plans and specifications which are now adopted by the department as standard types of construction, and he should, of course, be given ample time to prepare revised plans and specifications.

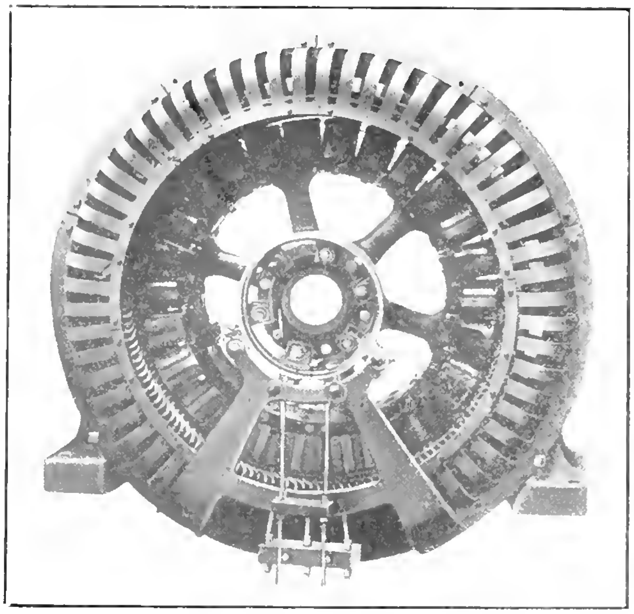
Supplementary agreements, radically changing the character of construction in work contracted for, should be avoided.

Specifications should be revised and should clearly describe the work to be done, and there should be a uniform interpretation of them by the department.

A thorough study of the highway map of the State should be made without delay. It should be revised where necessary, so as to unite the present State and county highway systems

SYNCHRONOUS MOTORS FOR DRIVING COMPRESSORS.

The use of synchronous motors for driving compressors is comparatively new practice. A few years ago the synchronous motor was not considered well adapted for this service but recent improvements in the design of these motors have entirely changed this view. To-day synchronous motor drive is used for many compressors in various parts of the country, and it has proved so efficient and reliable that the fact that this type of drive is the most satisfactory for this service can now be considered established.



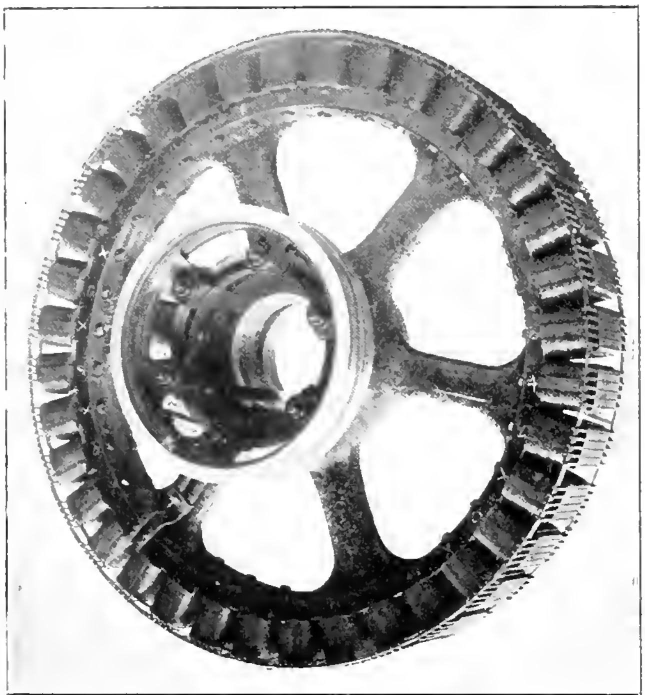
Synchronous Motor.

A typical example of this kind of utilization is furnished by the compressors at the Wickwire Mining Company's mines at Iron River, Mich. There are two compressors on this property, each driven by a Westinghouse self-starting synchronous motor. Both compressors are of Ingersoll-Rand make; one delivers 1,352 cubic feet of free air per minute at 200 r.p.m. and is driven by a 220 horse-power mo-

tor, and the other delivers 995 cubic feet of air at 235 r.p.m. and is driven by a 175 horse-power motor. These compressors have been in operation over a year and have proven very satisfactory.

As compared with other forms of drive for large compressors, synchronous motors possess a number of advantages. In the first place, the first cost of a synchronous motor compares very favorably with that of other types of motors or engines. The motor is especially adapted for direct connection, so that it costs less to install and takes up minimum floor space. The illustration shows what a compact unit is formed. The elimination of belts also decreases the maintenance expense.

The reliability of these motors in this service is proven beyond question. There are a number of installations which have been giving perfect satisfaction for a long time. A notable instance is that of the Anaconda mines where a total of 7,200 horse-power of Westinghouse synchronous motors have been driving compressors for nearly four years without a hitch, in spite of very variable operating conditions.



Synchronous Motor.

One of the chief objections to the old type of synchronous motor was the fact that it required some auxiliary starting device, but this difficulty has been eliminated. The modern synchronous motor is self-starting and self-synchronizing.

Another advantage of the synchronous motor is its ability to operate at 100 per cent. power factor, which tends to improve the operation of generators and to increase the capacity of transformers and transmission lines. If desired, these motors can be arranged to raise the power factor of the entire circuit by being supplied with excess capacity and used as synchronous condensers; thus greatly increasing the operating efficiency of the generating and transmission system.

The synchronous motors used at Wickwire represent the most modern design. They are characterized by great strength and simplicity of construction, as the illustrations show. The stator is supported by a heavy cast iron frame, and the coils are form wound and so arranged that they can be easily removed and replaced if the necessity ever arises. The rotor consists of a cast iron spider which carries the field poles. The windings are so arranged that they receive ample ventilation, and each field coil can be easily removed. An interesting feature of the rotor is the squirrel cage winding that encircles the field poles. This winding makes the motor self-starting and eliminates "hunting," or surging, which was one of the disadvantages of the early type of synchronous motors.

The Wickwire mine is operated from 6,600 volt, 60 cycle, three-phase power supplied by the Peninsular Power Company. This voltage is stepped down to 2,200 volts for the synchronous motors, and 220 volts for the motors for driving pumps and other apparatus.

THE IGNITION OF MINE GASES.

"The Ignition of Mine Gases by the Filaments of Incandescent Lamps," is the title of Bulletin No. 52, which has just been issued by the United States Bureau of Mines.

The authors, H. H. Clark and L. C. Ilsley, make the following general statement:—

As part of its investigations of the causes of mine accidents and of the safest and most efficient methods of handling electricity underground, the Bureau of Mines undertook a study of the ignition of mine gases by the filaments of electric incandescent lamps. This bulletin describes the investigation in detail and gives a complete record of the results obtained.

The investigation was undertaken for the purpose of determining the degree of danger that attends the use of certain specific sizes of incandescent lamps in atmospheres containing inflammable gas. Previous investigators have, to a greater or less extent, been concerned with certain theoretical features of the problem, such as the effect of the temperature and the dimensions of the lamp filaments; and the question whether a lamp may ignite gas by the heat of its glowing filament or by the spark that is drawn when the filament is broken. Although these features were considered in the present investigation and are briefly discussed in this bulletin, the principal object of the tests was to determine what sizes of incandescent lamps suitable for mine use would ignite explosive mixtures of mine gas and air, and what were the circumstances most effective in causing such ignition.

The results of the investigation may be generally summarized as follows:—

The naked carbon filaments of standard lamps, burning at rated voltage, will invariably ignite explosive gaseous mixtures.

If gas can reach the filaments of standard lamps without breaking the filaments of producing partial combustion within the bulbs, the explosive gaseous mixture is sure to be ignited.

Several sizes of both standard and miniature lamps, when smashed while burning at rated voltage, will ignite gas.

Standard lamps that do not usually ignite explosive gaseous mixtures may do so if the broken pieces of the filament cause a short circuit when the lamps are smashed.

Copies of this bulletin may be obtained by addressing the Director, Bureau of Mines, Washington, D.C.

SEWAGE DISPOSAL.

A report which speaks of the satisfactory working of percolating filters with granite chips as a medium was recently issued by the borough surveyor of Nuneaton, England. The quantity of sewage dealt with during the year was 425,590,000 gallons, which represents a daily average of 1,106,000 gallons, and is about 110,000,000 gallons in excess of the quantity treated in 1911.

The increase is mainly due to the heavy rainfall throughout the year, for many millions of gallons of sewage were pumped for treatment at Hartshill, which, under the old conditions, would have passed into the river direct from the sewers, and would have polluted the stream to this extent.

Of the 402,100,000 gallons treated at the Hartshill outfall works 340,751,000 gallons were dealt with by the filters, and the remaining 61,349,000 gallons by the primary contact beds and subsequent land irrigation. The effluent from the filters was at all times capable of supporting fish life in the outlet channels of the humus tanks, and was therefore discharged direct from the humus tanks into the river.

The seven primary contact beds were filled in the aggregate 7,708 times, equal to a daily average of three times each. The average liquid capacity was 45,900 gallons, as compared with an original capacity of 75,000 gallons, equal to a loss of 38.2 per cent. after eleven years' working. In the previous year the average liquid capacity of the primary beds worked out at 40,690 gallons, so that there has been an increase in capacity of 5,210 gallons per bed. The increase, in the opinion of the borough engineer, is probably due to the fact that the beds were worked more as balancing tanks for the percolating filters than as contact beds; consequently the period of quiesence was often materially less than the two hours generally allowed, and there was not the same opportunity for the deposit of suspended matter.

The last of the seven secondary beds converted into percolating filters was brought into use in May, thus completing the work of reconstruction commenced two years ago.

The continued satisfactory working of the percolating filters is the most gratifying feature of the works. Despite the fact that the medium in each filter consists of fine granite chippings with a 2-ft. 6-in. depth of ½-in. gauge at the surface, it has not needed cleansing in any way. The whole area of 1¾ acres is quite free from ponding. The clean condition of the medium is mainly due to the separating tanks with upward flow roughing filters, which were installed in connection with the recent extension of the works. The total area of the roughing filter in these tanks is only 54 sq. yds., but they have been thoroughly successful in the elimination of such suspended matter as has passed through the silt tanks.

Having regard to the success which has attended the conversion of the secondary contact beds into percolating filters, as well as to the continued increase in the flow of sewage, it has been decided that the primary beds shall be gradually dealt with in the same way. There is always a surplus of chippings produced at the quarry, and these will be utilized as they accumulate for this purpose. Very little expense will be incurred for ironwork until the filling of each bed is completed and it becomes necessary to fix the distributor, the cost of which will be about $3,000. The expense will be almost entirely in respect of superseding old work, so that it will be properly a revenue charge, and will not be felt so much as in the case of work executed under more rigid conditions. Each filter so provided will be capable of dealing with about 150,000 gallons per day.

CANADA'S RAILWAY TRANSPORTATION.

Prof. S. J. McLean recently delivered an instructive lecture on "Transportation" before the Canadian Club at Pembroke. He stated that the first railroad in Canada was built about 1838, and had wooden rails, and the motive power was horses. In 1868 there were 2,200 miles of railway in Canada; in 1878 there were 5,200 miles. This year there are about thirty thousand miles, or about the same as in Great Britain and Ireland. Last year 2,300 miles were built, or as much as between the years of 1836 and 1867. There are 8,000 miles under construction now, and about three-quarters of this is west of the Great Lakes.

In 1912 the average construction was four miles a day. Of the actual money gone into railways in Canada, 25 per cent. comes from the various provincial governments and the Dominion government, and the land grants, etc., amount to 17 per cent. more. Besides this, large amounts of the railway bonds are guaranteed.

In proportion to its resources, no other country contributes so liberally. There are such great developments west of the Great Lakes that very often the railroads cannot keep up with the advance. Last year 13,000 people went through Edmonton to the Peace River district, where they must work along as best they may until the railroad reaches them, some of them carting in their grain sixty-five miles over bad roads.

The formation of a railway commission was first taken up in Canada in 1860, and in 1880 Dalton McCarthy brought the matter to the attention of Parliament. In 1886 a Royal Commission was formed to conduct an investigation re changes of the general policy of the Railways Act, and in 1888 it was recommended that the commission be given power to deal with matters concerning preference and discrimination.

In 1904 the present commission was organized. The three central matters for their consideration are safety, service and rates. It is composed of six members, three members forming a section empowered to act so that two sections may act at once in different places.

There are three general departments: engineering, operating and traffic. They have a staff of five engineers, who are constantly on the road investigating railway matters, and they also have a staff of men to look after every department of railroad workings. Every working day the commission has 238 tariffs to consider, both local and international. For every case dealt with formally, there are six or seven dealt with informally. The cases coming before the commission involve items of from 15 cents to hundreds of thousands of dollars.

Three-quarters of the decisions of the commission are oral, being given immediately after the hearings. There were 609 decisions for the year ending in April, 1912. The commission is a perambulative body, and tries to get as close as possible to the individual complaint. The business of the commission is sane regulation, not management.

CANADIAN NORTHERN BUSY.

Work is in full swing on the Lulu Island branch of the Canadian Northern Railway running from the west boundary of New Westminster to Steveston at the mouth of the Fraser. The contracts, sub-contracts and station contracts are now being let and the grade will be completed by the beginning of June.

LARGE PAVING CONTRACT AWARDED.

Approximately $1,800,000 was voted recently by the Detroit, Michigan, city council for new pavements, and of this amount about $906,000, almost exactly one-half of the total, was earmarked to be used for paving with creosoted wood blocks. The remainder was divided among asphalt, granite and other types of pavements, about $400,000 being devoted to sheet asphalt.

Tenders for the supply of creosoted wood block were called for a few weeks ago. A special despatch to *The Canadian Engineer* last Monday announced that the Detroit city council had met and awarded the contract for the entire $906,000 worth of wood block paving to the United States Creosoting Company, of which the Canada Creosoting Company, whose plant is at Trenton, Ontario, is a branch.

A thorough investigation of paving materials was made in the year 1911 by the Detroit Board of Commerce. Foundations, manner of laying and methods of testing were studied, as well as every criticism that was advanced by the manufacturers of the various paving materials.

An interesting booklet announcing the results of the investigation has been issued under the title of "A Message from the Business Men of Detroit Regarding Their Pavements." Copies of this booklet will be sent to interested persons on request by the Canada Creosoting Company, Canadian Pacific Building, 1 King Street East, Toronto.

The first creosoted long leaf yellow pine wood block was laid in Detroit in 1905, and since then about 320,000 square yards have been laid. The only appropriation asked for the maintenance of the entire 320,000 square yards was $500, allowed in 1912. The specifications now in vogue in Detroit call for a 3½-inch block, with twenty pounds of creosote oil to the cubic foot. No guarantee deposit fund is required from the manufacturers, as past experience with the block has been so satisfactory that no charge could be made against such a fund.

The large demand for wood block came principally from property owners, not only in the downtown section but also in the residential section. There are now between sixty and seventy streets in Detroit laid with wood block, over seventy per cent. of the work being done by the city with its own men, under the title of resurfacing work. Some interesting data is given in the booklet above mentioned regarding just what wood block pavements are, their advantages, method of inspection, etc. The following quotations from the booklet are interesting:—

"For wood block pavements the favorite wood is yellow pine. To prevent decay, the wood blocks, after being cut, are placed in a cylinder and impregnated with creosote oil by a thorough vacuum process, which drives the creosote to the heart of the wood. The creosote, being a perfect antiseptic, makes the wood immune from wet rot or decay of any kind.

"The blocks are laid in the pavement on a foundation of concrete. The concrete is brought to a smooth surface by a coating of mortar or by the spreading of a sand cushion. The blocks are laid with the grain vertical with a tight joint and brought to a uniform level by tamping.

"The first effect of traffic on the wood block pavement is to broom the edges of the wood slightly, thus closing the joints and making them practically invisible, except near the curb where there is less wear. In consequence, wood block pavements frequently are mistaken for sheet asphalt.

"During the first year, traffic hammering upon the end of the grain pounds it down and mats the fibre, thereby reducing the total depth of the block by about one-eighth of an inch. The blocks cannot splinter or split because each block is imprisoned by the adjacent courses and has no room to spread. The wood does not wear away because of its resilient and fibrous nature. As a result of this hammering, the surface gets so tough that subsequent traffic has no effect upon it and during the next ten years the pavement, so far as can be seen, undergoes no change whatever.

"Modern wood block paving in the United States runs back to 1900, when the first creosoted wood pavements were laid in Massachusetts. The pavement on Tremont Street, Boston, laid in 1900, is still there and giving excellent service under the heavy traffic of that central thoroughfare There are now many miles of wood block pavement in the principal American cities, notably New York, Chicago, St. Louis, St. Paul and Philadelphia. It is widely recognized by engineers to be the highest type of pavement and has been so recognized abroad for many years. The great streets of the world, such as Champs Elysees of Paris, and The Strand and Regent Street, London, are paved with wood.

"Briefly summarized, the advantages of wood block pavement are maximum durability, no expense for maintenance, noiselessness (an important civic asset), cleanliness, perfect contour, creates no dust, reflects less heat than lithic pavements, gives easy traction.

"The commissioner of public works, on the awarding of a contract for creosoted block, appoints a responsible chemical testing bureau as the city's representative to see that the specifications adopted by the city are absolutely lived up to.

"The chemists are sent to the plant of the manufacturer as soon as the process of manufacture is started. The oils are analyzed, the lumber inspected, and an accurate record kept of the quantity of oil impregnated in each cubic foot of lumber.

"The daily record of car numbers, showing contents of cars with name of consigneee is forwarded to the commissioner of public works, together with a statement analysis of the oil and the grade of lumber.

"Material not in accordance with the specifications is rejected at the manufacturing plant."

The booklet is well illustrated with fifty photographs of Detroit Streets and about an equal number of photographs of letters from Detroit firms relating their experiences with wood block pavements.

HIGHEST AND LOWEST POINTS IN THE WORLD.

The maximum difference in elevation of land in the United States is 14,777 feet, according to the United States Geological Survey, Mount Whitney, the highest point, is 14,501 feet above sea level, and a point in Death Valley is 276 feet below sea level. These two points, which are both in California, are less than 90 miles apart. This difference is small, however, as compared with the figures for Asia. Mount Everest rises 29,002 feet above sea level, whereas the shores of the Dead Sea are 1,290 feet below sea level, a total difference in land heights of 30,292 feet. Mount Everest has never been climbed.

The greatest ocean depth yet found is 32,088 feet, at a point about 40 miles north of the island of Mindanao, in the Philippine Islands. The ocean bottom at this point is therefore more than 11½ miles below the summit of Mount Everest.

The difference in the land heights in Europe is about 15,868 feet.

COAST TO COAST.

Montreal, Que.—A strong movement has been inaugurated to induce the Federal and Provincial Governments to subsidize the construction of a highway between Montreal, Ottawa and Toronto, and to improve the highways and bridges in the interests of trade and commerce, and of better communications between these points. At a recent meeting of the city council of this city it was proposed to send a delegation to Ottawa to interview the government authorities regarding the project and to ask the government to take steps in the furthering of the scheme by voting the money necessary for roads and bridges. As the construction of this roadway would be very advantageous, the voting of the money should meet with public approbation.

Quebec, Que.—At present there is not sufficient or adequate dock accommodation on either the Atlantic or the Pacific Oceans for steamships which ply regularly to and from Canadian ports. It is authoritatively stated that the government intend to proceed immediately with the construction of modern and up-to-date docks at Halifax, Quebec and Esquimalt, capable of receiving and docking the largest steamships plying on the Atlantic or on the Pacific. The best expert advice as to the type, size and location and character of these docks will be secured. They will be available not only for merchant steamships in need of repair and examination, but also for ships of war in case of need. The advice of the Admiralty as to all matters which concern the utility of these docks for purpose of the navy in time of war will be sought.

Ottawa, Ont.—The Publicity and Industrial Bureau of the city of Ottawa, of which Mr. Herbert W. Baker is commissioner, has just sent out a most interesting map showing the water powers, minerals and transportation facilities within a radius of 60 miles of the city of Ottawa. According to the map there is shown the low-water estimate of nearly 2,300,000 horse-power within a radius of 60 miles of the city, of which 150,000 horse-power is developed. It furthermore shows that twelve steam lines radiate from Ottawa with two electric lines proposed, as are shown on the map. The water powers, as shown on the map, indicate the horse-power available and their location in respect of the city of Ottawa. Those interested in receiving a copy of this map may do so by addressing H. W. Baker, Industrial Commissioner, Ottawa, Ont. It is well worth having.

Toronto, Ont.—Word comes from Washington that a preliminary report on the recent experience in radio-telegraphy between the scout cruiser Salem, on her voyage to and from Gibraltar, and the great wireless tower at Arlington, had proved this station to be second to none in the world, not excepting Eiffel Tower or the great German wireless towers. In this first test the contract requirement of the despatch of messages from Arlington to a vessel at least 3,000 miles distant could be only realized at night, but such messages were delivered to the same by day up to a distance of 2,383 miles. It was demonstrated, too, by the use of kites on the vessels with wire conductors, messages could have been exchanged throughout the entire transatlantic trip. Results of interesting experiments made during this voyage with new forms of apparatus are said to mark a new era in long distance radio communication.

Cochrane, Ont.—It is reported that the Transcontinental Railway Commission has let the contract for the installation of a pick up water system, and that work will commence May 1. Cochrane will be the headquarters of the district for the company which has charge of the work. Engineers were here last winter to inspect the line and n[illegible] how the water could be prevented from freezing. They recommended in their report that troughs be placed every twenty miles. There will be double troughs with steam pipes running between them.

The construction of these will be a big undertaking as they will have to be laid in beds of cement and iron stays imbedded to prevent the rails from spreading. The cement work will also have to be of the best and special men are carried by the company, which installed the system on many of the big railroads in the United States.

Victoria, B.C.—The list as prepared by the Chief Forester of fires shows that 20 of the fires were caused by campers. The list is as follows:—Campers, 38; railway locomotives, 34; lightning, 23; donkey engines, 11; railway construction, 11; public road construction, 9; uncontrolled permit fires, 8; smokers, 7; accidents, 6; logging railways, 6; prospectors, 3; Indians, 3. Stringent regulations have been passed by the Board of Railway Commissioners of Canada to cover the risk of new railroads under construction in the province, the patrol has been doubled on the rights of way, and every possible precaution urged upon logging operations. The Forest Branch is endeavoring to co-operate in every way with those who have work to perform which is attended with danger to the forest. But the greatest danger of all, that of the man who is careless with his camp fire, still remains open, and it can be removed only by increased watchfulness on the part of every individual who uses the woods for pleasure or profit.

Montreal, Que.—It has been proved by evidence before coroners' juries and by the testimony of eye-witnesses that many drownings in the Lacbine Canal and along the docks would never have taken place if the victim had means within his reach to pull himself to the solid shore. Many a good swimmer who has accidentally fallen over into the water on a dark night, when no help was near, has swam about till exhausted vainly striving to secure a hold on something which would enable him to pull himself out of the water. With this knowledge in mind, Mr. Frederick J. Gilman, C.E., has invented a contrivance which, if accepted by the Dominion government, would prove helpful in life-saving, not only of persons who are so unfortunate as to fall into the water, but to help the rescuers to get them out. This invention is exceedingly simple, consisting of stringing of stout wires along the walls of the canal or harbor within easy reach of any person in the water. Above these at certain intervals are a series of other wires which would enable a person to get up on the banks.

Regina, Sask.—A first-class system of provincial highways, linking up the various parts of the province, is the latest plan of the Highway Commission, according to the statement made recently by Mr. A. J. McPherson, chairman of the commission. The idea is to provide broad and well-kept highways joining towns and villages for a hundred miles or so in different directions. For instance, one road will probably run from Swift Current to Fleming. Another will pass through Estevan, Weyburn, Regina, Moose Jaw, Saskatoon and Prince Albert—generally north and south. Still another will go from Saskatoon west to Kindersley, Kerrobert, Scott, Macklin, etc. Another will probably be from Lloydminster to Battleford. The latter, in fact, is being taken up by the municipalities themselves, and is likely to be constructed in the near future. Considerable portions of these main roads will be built by the municipalities, under the municipal roadmaking scheme. It is estimated that nearly $10 per capita will be spent by the people of Saskatchewan this year on road making. The government pro-

poses to spend about two million, and the municipalities will, it is expected, spend about three million dollars.

Ottawa, Ont.—A large deputation from Toronto, Montreal, Prescott, Cornwall, Belleville and other places seeking government assistance for the furthering of a trunk road between Montreal and Toronto which would pass through Ottawa and serve a number of other Ontario and Quebec towns and cities. The scheme, as proposed, is for a highway between Toronto and Montreal which would not only connect the two largest cities in Canada, as well as Ottawa, but would develop the rural districts along its route by bringing business to them. To gain the shortest possible route a bridge must be built across the Ottawa River connecting the Island of Montreal with the mainland in Vaudreuil county, and government assistance in its construction was requested of Hon. Robert Rogers, minister of public works. Montreal was largely represented in the delegation, among the civic authorities being Controller Godfrey and Aldermen L. A. Lapointe, Monahan and Menard. The Canadian Manufacturers' Association, the Montreal chamber of commerce, the interprovincial highway and bridge committee, the boards of trade of Cornwall, Prescott, Kingston and other towns were also included, one delegate, Col. Ponton, of Belleville, representing 63 boards of trade. Ex-Mayor Geary and Controller T. L. Church were among the Toronto representatives.

Montreal, Que.—The decision to use the space between the inner and outer shells of the Olympic for the storage of oil, to be experimentally used as fuel for one of the mighty boilers, is an interesting development in the use of oil as fuel which is so familiar a practice on certain Western railways. Nor is the use of oil for vessels any longer a novelty. One steamship company, with headquarters in the Far East, has twenty-one oil-burning ships in its service; two transatlantic lines have vessels equipped with apparatus enabling them to utilize oil. Indeed, the liquid fuel is far more generally used at sea than on land. A great advantage is that, instead of the difficult transmission of coal bags from a collier, oil can be pumped through flexible tubes into the hold of a ship to be supplied in rough weather. In such a ship as the Olympic there is an enormous saving of cargo room through the possibility of oil storage in space not otherwise utilized. The German fleet on the China station regularly uses oil; so do the ships of the Dutch navy and the Italian Admiralty. In the Far East, since Sir Marcus Samuel developed the Borneo oil fields, there are rich supplies for the constantly increasing use of liquid fuel throughout the surrounding region, supplemented by the product of the valuable oil wells in Burmah. The advantages, in brief, are the reduction in weight and space and number of men; the absence of cinders and the control of smoke; the ease with which an even temperature can be maintained; the absence of cumbersome gear for handling the coal and the ashes therefrom.

Calgary, Alta.—The department of mines was regarded by the mining engineers of Canada as an urgent necessity if the interests of the industry are to be thoroughly looked after and successfully promoted, was the statement made by Mr. E. A. Scovil, who recently attended the session of the Canadian Institute of Mining Engineers, held at Ottawa. Hitherto the mines have been under the supervision of the secretary of state, but the work has grown to such proportions that it is now imperative that a special portfolio be created in order that it may be properly attended to. The secretary of state is already loaded down with work properly appertained to his own department, and it is impossible for him to give that attention to the mining industry that it deserves. During the past few years immensely valuable mining areas have been opened up throughout Canada, more especially in Northern Ontario and in British Columbia, and the activities of the mining men of the Dominion are being rapidly extended. The experts gathered together in Ottawa, Mr. Scovil said, had considered the situation from every angle and the profitable course for Canada, they had concluded, was an establishment of a department of mines for Canada. In this opinion they were in perfect accord with mining men not members of the institute, and it was expected by all that the matter will be presented to the government so convincingly that the new department will shortly be formed.

Calgary, Alta.—The C.P.R. has opened its new shops at Ogden, near here, which are the largest railway repair shops in the world. The opening of these shops marks a new era in the annals of Calgary and district, if not the Canadian West, for where less than twelve months ago was open prairie land to-day there exists a great hive of industry. The C.P.R. has already expended several millions of dollars on the erection of buildings and equipment forming these huge and colossal works, but there still remains more to be done before the shops reach the state of perfection which is always a part of the policy of the C.P.R. The shops are of the most modern construction, and contain the latest appliances used in the construction or the repair of a locomotive that the mechanical world has devised. Eleven and a half months from the turning of the first sod for the construction of the works the C.P.R. turned out its first engine. The contract for the shops was let to the Westinghouse, Church-Kerr Company, and Mr. T. N. Gilmore, the railway equipment engineer for the contractors, supervised the work. The power plant is one of the largest in the West, containing six Babcock & Wilcox boilers, capable of developing 2,100 h.p. A concrete smoke stack, 250 ft. high, provides the draught for the boilers. The steel work itself is a revelation, no less than seven millions of pounds having been utilized in the buildings. The capacity of the locomotive shops, which will be used for the present to do heavy work on the engines, will be between six and eight hundred locomotives a year. The shops will be a great acquisition in the West, and will materially assist the company in keeping its huge rolling stock in the highest state of efficiency.

Victoria, B.C.—The government is anxious in the interest of the country, to have the timber for sale along the Grand Trunk Pacific, between Yellow Head Pass and Fort George, taken out and used before decay and insects get a firm hold. As is well known, dead timber is not able to resist either of these enemies, and it is only a matter of time before what was perfectly healthy wood is filled with a network of insects' borings and fungus growth. Damages to the extent of over $5,000,000 annually are estimated to take place in Eastern Canada and the United States. These losses may not be paralleled in the West, but there is undoubtedly vast depreciation going on at all times and this will become more and more noticeable as time goes on and timber and values increase. Logging fire-killed timber involves losses in many ways, particularly in bringing useless parts of the tree to the mill, and in the danger of breaking when the trees are being felled. There are difficulties in milling, in that the soft, punky outside layers of decayed logs take up gravel which is bad for the saw. The average results of tests of small specimens free from defects indicate that the wood of fire-killed Douglas fir, after a considerable number of years, is slightly weaker than that cut from green timber. The difference, however, is not great, and in structural sizes containing the defects ordinarily found in timber, very largely disappears. In tests which have been conducted bridge stringers of fire-killed wood proved to be somewhat less strong than the green

stringers with which they were compared; while the floor joists (of both kinds of wood) were about equal in strength. In stiffness, the fire-killed wood was fully equal to the green wood for all sizes tested. In general, tests indicate that the sound wood from fire-killed Douglas fir of the Pacific Coast may safely be used for general construction purposes, and that its merits are nearly, if not quite equal to those of material from green, growing trees. It should be emphasized, however, that these results apply only to sound wood. Pieces showing indications of decay, whether cut from green or from dead trees, should be rigidly excluded where strength or durability is important.

Victoria, B.C.—Mr. W. A. Young, the new comptroller of water rights, who is also an engineer, has been very busy lately outlining the work to be undertaken this year by the hydrographic engineers employed by the provincial government. A systematic survey of the water courses, to determine their capacity for power, irrigation and other purposes, is to be made this year in the farther outlying districts of the province. Last year the Kootenay, Okanagan, Thompson, Fraser, Nicola and Similkameen valleys were well covered; but this year these sections are to be more thoroughly examined and mapped. The government is issuing maps of the various watersheds as completed, showing the capacities of the various creeks and rivers. A feature of the policy is the assignation of different engineers to certain fixed districts, in which they will have full charge of all matters connected with hydrographic work. They are also special commissioners to investigate difficulties arising in claims for water rights, having the power to report the best policy to adopt where there is a conflict between ranchers and others.

PERSONAL.

H. L. FITZSIMMONS, of the Toronto city engineers' department, has been appointed building inspector of Prince Albert, Sask.

MR. LESLIE T. STONE, assistant engineer of the Grand Trunk Railway, at London, has been appointed division engineer.

MR. J. G. MILL is resigning from the city engineer's department, Toronto, and has been awarded the contract at Brighton, Ont., for the waterworks installation. The town will expend $50,000 on same.

MR. T. A. MURRAY, consulting engineer, Toronto, is leaving Friday, April 17th, for a month's trip to Fort William and Kenora, and as far west as Macleod, Alta., in connection with his business interests in the West.

GEO. T. CLARK'S resignation, which he recently tendered as city engineeer of Saskatoon, has been reconsidered by the council, as a result of which Mr. Clark will continue in the capacity of city engineer of that city.

MR. FREDERICK G. GOODSPEED, formerly of Penniac, York county, has been appointed acting district engineer for the federal department of public works with headquarters in St. John, N.B., succeeding Mr. J. K. Scammell, resigned.

ARTHUR H. BLANCHARD, M.Can.Soc.C.E., professor of Highway Engineering, Columbia University, on April 10th delivered an illustrated address entitled "Modern Bituminous Pavements for Municipalities" before the Board of Trade of Elizabeth, N.J.

MR. GEO. W. THOMPSON has been appointed temporary acting controller by the city council of Westmount, Que. Many applications for the position had been received from England and the United States, as well as throughout the Dominion. Mr. Thompson was previously superintendent of the light and power department of the city.

MR. CHAS. E. FRASER, B.Sc., graduate of McGill University, class of 1899, and partner of the firm of Fraser, Brace & Company, of New York, it seems, has been awarded the $3,000,000 contract for the development of the Cedar Rapids Manufacturing Co. works. Mr. Fraser's firm has also carried out successfully a considerable number of large and important contracts. Among these were the construction of a big power dam at Shelbourne, Mass., a bridge contract in the New England States, a power flume on the United States side of the Niagara Falls, and the most difficult portion of the development works of the Canadian Light and Power Company at Valleyfield, being in connection with the locks of the waterway.

F. W. THOROLD, B.A.Sc., Toronto, has incorporated the F. W. Thorold Company, Limited, consulting engineers and contractors. Mr. Thorold has had fifteen years' experience in engineering and contracting work in all parts of Canada. He was formerly chief assistant engineer for the city of Toronto, and for four years was city engineer of Calgary, Alta. He has successfully designed and superintended the construction of numerous sewerage and waterworks systems, hydro-electric developments, etc., and has conducted a large number of important surveys. The F. W. Thorold Company will specialize on municipal work and public utilities. It is the intention of the firm to make surveys, designs and reports in regard to public utilities, construct them on a contract or cost plus percentage basis and turn them over to a town or city in running order.

The following are the names of some of the engineers who have been assigned to fixed districts in regards to the hydrographic work of the British Columbia Government: Mr. W. G. E. Biker, who surveyed part of the Kootenay watersheds and determined the power which is available in the Cranbrook water district, is this year to make an exhaustive examination of the water power in and around Nelson. Mr. O. J. Bergoust, who reported on the upper Similkameen and part of the Okanagan watersheds, will this year be stationed at Revelstoke to make hydrographic observations. Mr. H. B. Hicks will continue his work in the Kootenay watershed. Mr. P. J. de Latour is already in the field with a party, with headquarters at Nicola Lake.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

The headquarters of the Canadian Society of Civil Engineers were last Friday moved from 413 Dorchester Street West to 176 Mansfield Street, Montreal. Owing to this removal the regular monthly meeting scheduled for the 10th has been postponed to the 24th instant.

Announcement is made of the thirteenth annual six weeks summer school of the College of Engineering of the University of Wisconsin, which opens on the 23rd of June.

Courses of instruction and laboratory practice are offered in Electrical, Hydraulic, Steam and Gas Engineering, Mechanical Drawing, Applied Mechanics, Testing of Materials, Machine Design, Shopwork and Surveying, in addition to which subjects may be taken in the College of Letters and Science.

For bulletin address F. E. Turneaure, University of Wisconsin, Madison, Wisconsin.

THE INTERNATIONAL ROAD CONGRESS.

The city of London has issued an invitation to the members of the International Road Congress, in session June 23 to 28, 1913, to attend a conversazione, to be held in the ancient Guild Hall, to meet the mayor, aldermen, and common councillors of the city of London.

The delegates will be entertained with the traditional hospitality for which the city corporation is famous. The Guild Hall, with all its art treasures and its historic records will be open to the visitors. A dance will be given in the famous library, which will be specially arranged for the occasion. A concert will be given for those musically inclined in the council chamber.

We understand that a number of well-known Canadian road engineers and others interested in the "Good Roads" movement have intimated their intention of attending the congress.

There will necessarily be some limit to the number of those to whom invitations to these special functions can be issued, and those interested in the roads in Canada who intend to proceed to London and have not informed Mr. Rees Jeffreys, general secretary, of their intention to do so should communicate with him without delay at Queen Anne's Chambers, Broadway, Westminster, London, S.W.

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, T. S. Young, 220 King Street W., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Mucklestone; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson, Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290. Meets 2nd Thursday in each month at Club Rooms, 584 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

TOWER STREET ARCH BRIDGE AT FERGUS

By A. W. CONNOR*

We illustrate in this article a reinforced concrete arch bridge over the Grand River, recently completed at Fergus, Ont., for the county of Wellington. The bridge proper has a length of 100 feet and clear span of 80 feet. There is a clear roadway of 16 feet and two 4-foot 6-inch sidewalks, carried on brackets at each side. It is a bridge of the open-spandrel type, carried on two ribs, resting on which are subsidiary spandrel arches, columns, floor beams and slabs. The open spandrel arches are purely ornamental. Fig. 3 shows an elevation and Fig. 4 a cross-section which indicates how the structure is built up from the supporting ribs.

The site is well adapted for this type of structure, the abutments being on a rocky ledge on the banks of the Grand River. This ledge of rock is about 16 feet above the low-water level and about 20 feet below the road level. The rock is limestone. The concrete structure is considered to be in harmony with the scenery.

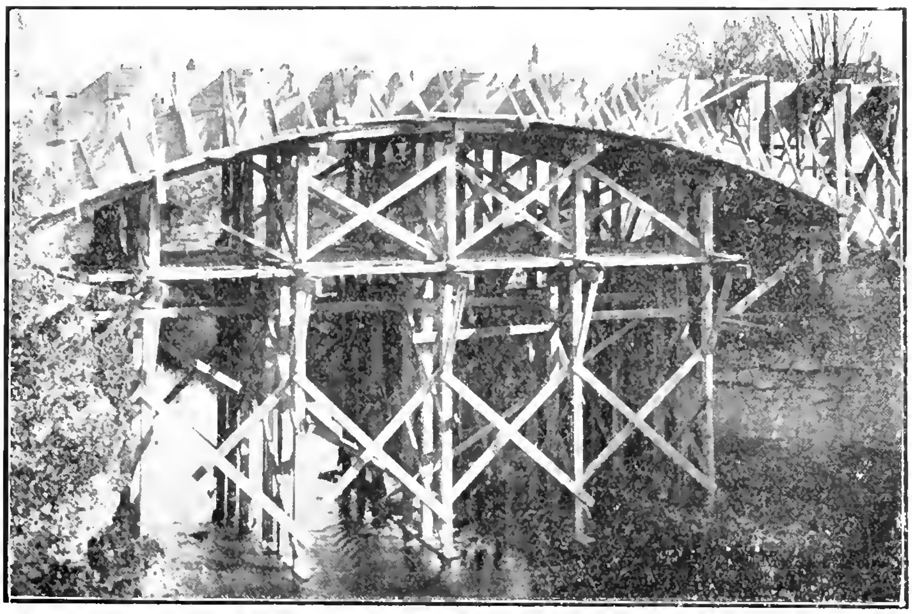

Fig. 1.—Showing Superstructure of Bridge.

The old structure was a steel deck pin-connected bridge of 75 feet span, centre to centre, resting on stone abutments, built on the same ledge. As the photograph shows, this rock has been undercut by the water. The abutments of the new bridge have been carried further back to avoid future undermining, and the arch design was favored by the engineers, as the thrust of the arch would tend to hold up the structure, even if partly undermined. The amount of the undermining was carefully determined and the faces of the abutments were set about five feet clear of the erosions. Some of the projecting portions of the rock were badly cracked, and these, together with parts necessary for getting in the foundations, were blasted off. The rock thus thrown into the stream formed a convenient means of reducing the depth of the water for setting of falseworks. The old stone east abutment, which was in poor condition, was also taken down and thrown into the river, the ends of the steel bridge being supported by a temporary wooden bent. The new west abutment was in front of the old and was carried partly below it.

The abutments were built larger than shown on the plan, being flared out to give a larger bearing on the rock.

The falseworks were then erected in the bed of the stream. On account of the height of the work the contractor took the precaution to build a working platform under the old bridge. The old structure was then taken down with a gin pole, and short bents on top of this carried the centering.

The forms for spandrels and columns were then set up. The alignment was kept by stretching two copper wires in the line of the spandrels and at the level of the crown of the roadway, which was cambered 8½ inches at the middle of the span. Care was required to get the floor beams and the circular openings in the spandrels at the proper levels. These circles were formed with sheet iron. The panel points on the ribs were finished approximately horizontal, and reinforcing rods set in to receive the columns, which were 12 inches by 48 inches wide.

All the columns were then built to the level of the floor beams. The beams and floor slab were then built together and the floor finish (a 1:2 mortar) applied as the work progressed from either end. The steel for the cantilever brackets was left projecting. There brackets were next built up to the underside of the sidewalk slab. The curb, sidewalk and

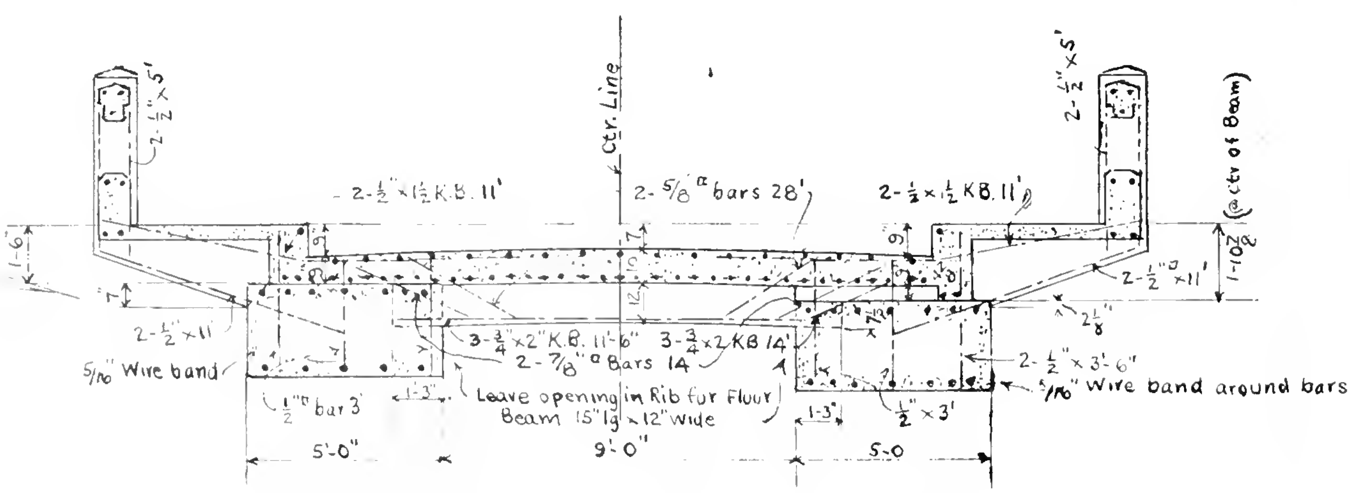
DESIGN FOR 80-FT. x 25-FT. CONCRETE ARCH BRIDGE OVER GRAND RIVER AT FERGUS, ONT.



Half Cross Section at "DD."

Half Cross Section at "CC."

SECTIONS OF CONCRETE ARCH BRIDGE.

NOTE.—Designed for live load of 125 lbs. per sq. ft., or 10 and 6 tons at 10-ft. centres on roadway and 100 lbs. per sq. ft. of sidewalk. All concrete 1:2:4. Where joints have to be made set forms square with surface with steel projecting through. Joints in beams and slabs to be at centre of span.

bottom part of the railing, which acts as a girder for the sidewalk slab, were then built together, and the sidewalk finished before the base had set.

The forms for the hand-rail posts and upper rail were then set up, the spindles, which were cast as the work progressed from C.I. moulds furnished by the county, were set in position and the upper rail cast around the tops of them.

Fig. 2.—View Partially Showing Under Portion of Bridge.

A ledge in the top of the lower rail was left for these spindles and this was then grouted in.

The roadway is finished as an ordinary concrete bridge floor, with a crown of 2 inches. The curb is 9 inches high, so that at some future time asphalt blocks or other paving material may be used.

Concrete cross walls were built up at both ends of the bridge. At the east end retaining walls 85 feet on one side and 135 feet long at the other side carry the roadway down to grade level. The railing on the retaining walls is a solid one with panels and posts at 16-foot centres. It is built to harmonize with the railing on the bridge, but less striking so as not to detract from the arch itself.

The bridge was designed as a parabolic arch without hinges to carry a live load of 125 pounds per square foot of the roadway and 100 pounds on the sidewalks. The roadway is also figured to carry a concentrated load of 10 and 6

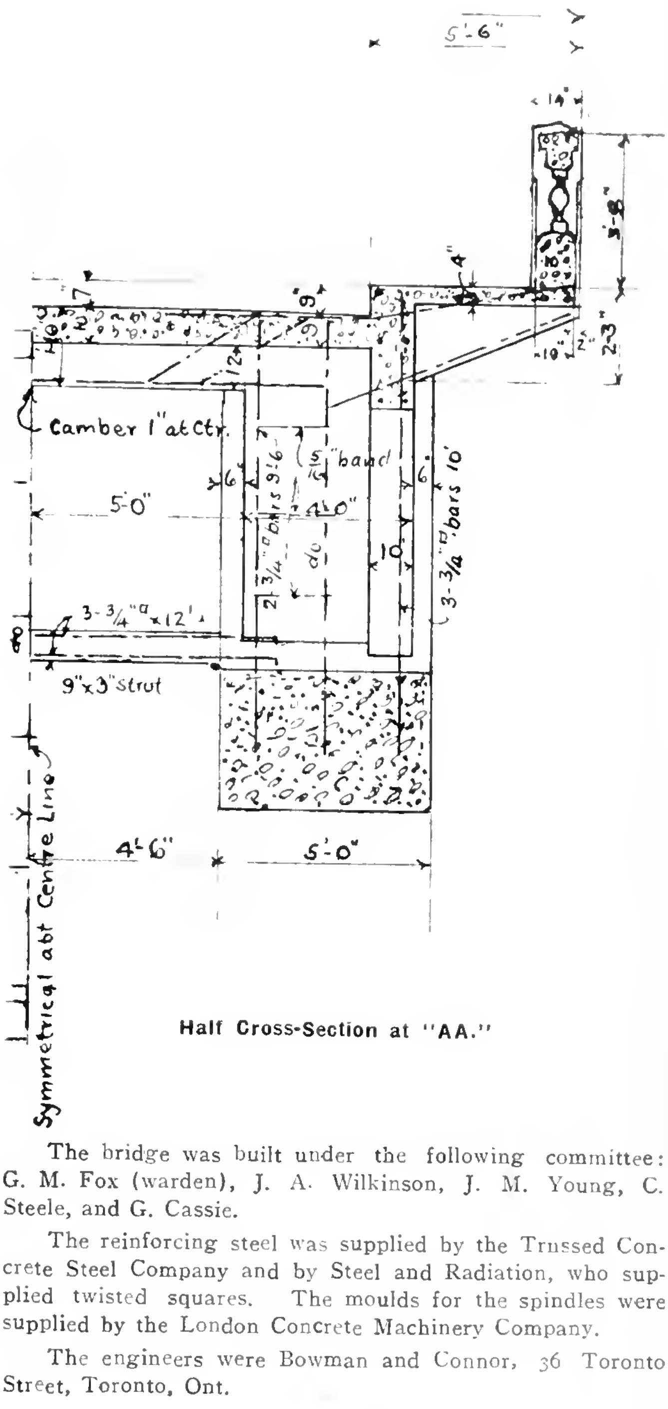
Fig. 6.—View of Bridge on Completion.

tons on two axles 10-foot centres. A temperature variation of 100 degrees Fahrenheit was also allowed for.

There are 316 cubic yards of concrete in the arch proper, with end cross walls, which are 100 feet apart. The cost of this was about $4,800. The retaining walls on the east approach contained 204 cubic yards of concrete and cost about $1,300.

All the concrete was mixed in the proportion of 1:2:4. There was no surface treatment except a wash of cement and waterproofing mixture. The finish was very good and reflects great credit on the contractor, Mr. W. M. G. Davies, of Stratford, Ont.

The bridge proper was begun in July, 1911, and finished before winter. The retaining walls were built the following spring. No crack has yet appeared in any part of the bridge



Half Cross-Section at "AA."

The bridge was built under the following committee: G. M. Fox (warden), J. A. Wilkinson, J. M. Young, C. Steele, and G. Cassie.

The reinforcing steel was supplied by the Trussed Concrete Steel Company and by Steel and Radiation, who supplied twisted squares. The moulds for the spindles were supplied by the London Concrete Machinery Company.

The engineers were Bowman and Connor, 36 Toronto Street, Toronto, Ont.

The Newfoundland government propose to extend the telegraph system around the seaboard of the island, 500 miles having been built in the past four years, with a prospect of 250 more being constructed during the present season; also to build three more wireless stations on Labrador and to establish a telephone system for St. Johns and a number of the outlying places.

ASTRONOMICAL STUDY OF THE UNIVERSE.

At the annual meeting for 1913 of the Royal Astronomical Society of Canada the president, Mr. L. B. Stewart, professor of Astronomy at the University of Toronto, in his presidential address, spoke on "The Structure of the Universe." That portion of his address which we believe will be of most interest to our general readers we abstract and publish as follows:—

It is proposed to sketch briefly the methods of investigation used in the study of the universe, the principal facts that have been learned up to the present, and some probable conclusions that may be drawn from those facts.

If it were possible to measure the distances of the stars with the ease and precision of determinations of direction, the investigation of the form of the stellar universe, and the distribution and motions of its individual members, would be a simple question of time and labor; but unfortunately astronomers are met at the outset by the impossibility of determining by direct methods, the distances of any but a few hundreds of the millions of stars that can be seen in our telescopes.

The only direct method of determining the distance of an individual star is by observing the difference in its direction as seen from the earth when at opposite points of its orbit. This is double the star's annual parallax. The relative method, by which these determinations are usually made, is admittedly unsatisfactory, especially in the case of small parallaxes, as it gives only the difference between the parallax of the star under investigation and the mean of those of the comparison stars, so that the result is always too small, and is frequently negative, showing that the parallax star is farther away than the mean distance of the comparison stars.

Another method—of limited application, as it can only be applied to binaries—has been recently used with success to determine the parallax of such systems. Micrometer measurements give the angular dimensions of the relative orbit of a pair of stars that are physically connected; but it was shown by Fox Talbot in 1871 that if in addition the radial velocities of the individual stars are found by means of the spectroscope, the absolute dimensions of the orbit of each star about the centre of gravity of the system, the masses of the individual stars, and finally their parallax, could be computed. In order that the method may be applicable it is necessary that the stars be separable in the field of the telescope. Burnham has separated stars closer to one another than 0".25, and it is considered possible to separate stars as close to one another as 0".1. In the cases of very distant binaries, if separable, they are situated at such wide distances apart that their relative motion is so slow that centuries must elapse before their orbits can be determined.

A method depending upon a study of the proper motions of the stars of a group, which may be used to obtain the mean parallax of the group, may be thus briefly described: The observed proper motion of a star is compounded of a real motion of the star in space projected upon the celestial sphere, and an apparent motion, termed the parallactic motion, resulting from that of thee solar system. This observed proper motion may be resolved into two others, one perpendicular to the direction of the sun's way, the other parallel to it. The former is termed the τ component and is independent of the solar motion, and the latter the apical component. This latter is composed of the resolved part of the true proper motion of the star, and the parallactic motion.

Having outlined thus briefly the principal methods of investigation that are applied to the stellar universe, let us turn next to some of the results of the investigations that have been made, and the conclusions reached by their discussion.

Before doing so, however, it will be well to place before us some of the questions to which answers are sought, in prosecuting the study of our stellar system. The following are some of these questions:

Is the universe infinite in extent? If finite, are there other systems separated from ours by immeasurable distances; or do all the stars, nebulæ and clusters, that are visible in our telescopes, or on our photographic plates, form a single system; or are the nebulæ, or some of them, separate systems situated at such vast distances from us as to be irresolvable? Have our telescopes penetrated to the confines of the stellar universe, so that the stars that are brought to light by increased power, or longer exposure, are merely fainter stars and not more distant ones?

As before stated, a full answer to these questions cannot be given at present, and possibly a complete solution of the problem will never be reached, though probably the main conclusions arrived at by a discussion of the facts now in our possession will only be modified by future discoveries.

That the universe is finite in extent has long been considered as proved, from the fact that, if infinite, the heavens would shine everywhere with a brightness equal, at least, to that of our sun. This conclusion is only valid if there is no absorption of light in its passage through space; and experimental evidence seems to be accumulating which points to a possibility that there is such absorption, though the evidence cannot be considered entirely convincing.

Prof. Newcomb's conclusions regarding the extent of the universe may be thus summarized: The universe is limited in extent, and probably extends farther in the plane of the Milky Way than in the direction of its poles, but in every direction much farther than the limit within which the proper motions of stars have yet been determined. The boundary is probably somewhat irregular, and the stars gradually thin out as it is approached. It is quite possible that far outside our universe there may be collections of stars of which we know nothing. It is not possible to decide whether the star masses of the Milky Way lie on the boundaries of the universe or not; the number of lucid stars that seem to lie within the Milky Way favor the view that that body is contained within the stellar universe. The stars lying without the galactic region show no tendency to collect in clusters, but are distributed throughout space with some approach to uniformity.

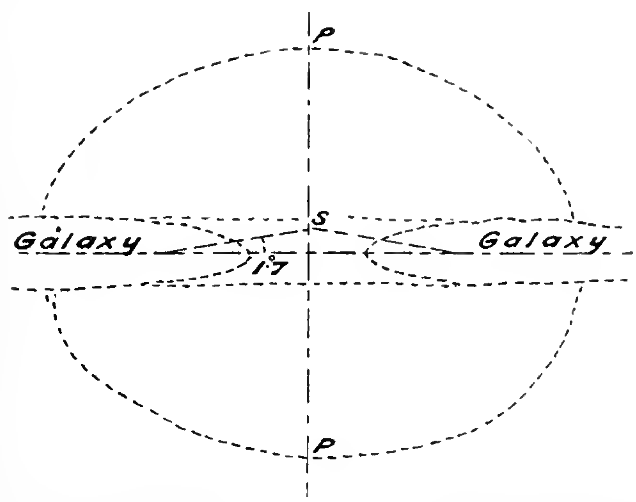
Several estimates of the distance of the Milky Way have been made, based upon different principles and assumptions, and which therefore differ widely in their numerical amounts. Professor Very makes an estimate of its distance by means of the parallax of Nova Persei. Bergstrand had found that quantity to be 0".03, but from considerations based upon the rate of expansion of the nebulosity seen to surround the star after the outburst, Professor Very concluded that his value was too small, and placed it at 0".05. This makes the distance about 60 light years. He assumed the nova to be situated within the condensed part of the spiral structure of the galaxy; and it may be remarked here that nearly all the novæ recorded during the last 300 years are situated in or very near the galaxy, and so appear to be in some way connected with it.

He then proceeds to estimate the distance of the Andromeda nebula in a similar way. A nova appeared in the centre of the nebula in 1885, and attained the 7th magnitude. By assuming its intrinsic brightness to be equal to that of a galactic star of zero magnitude, its distance is found to be

1,579, or approximately 1,600 light years. He finally expresses the opinion that the smallest and faintest of the white nebulæ may be galaxies at a distance of 1,000,000 light years, thus advocating the theory advanced by Herschel, that our stellar system is quite limited in extent, and of the form of a spiral nebula, and that the spiral nebulæ are similar systems separated from ours by vast distances.

Some have found a difficulty in reconciling the above moderate estimate of the distance of the Milky Way with the accepted fact that the stars having sensible proper motions are probably much nearer than the Milky Way, and have smaller parallaxes than that corresponding to the above estimated distance. It may also be observed that as the spiral nebulæ congregated in the neighborhood of the galactic poles, they are probably part of our stellar system; certainly that fact does not strengthen the view that these nebulæ are separate systems.

It occurred to me recently that an estimate of the distance of the galaxy may be made by a purely geometrical process, which is here given for what it is worth. It has been shown that the galaxy is not quite a great circle of the celestial sphere, but lies in about 1°.7 south galactic latitude, showing that the solar system is a little to the north of the galactic plane. This conclusion is strengthened by the ob-



P.P.—Poles of Milky Way. S.—Position of Solar System.

Hypothetical Form of the Universe. Section Through the Poles of the Galaxy.

served greater star density in the direction of the south pole than in that of the north pole, Seeliger having found the densities to be 3.14 and 2.78 respectively, per square degree. If it be assumed that this difference of density is due solely to differenc of distance, the distances of the poles of the galaxy will then be to one another in the ratio of the cube roots of the above star densities, or .96. Then if the additional assumption is made that the galactic plane divides the stellar universe equally, it is found that the distance of the solar system to the north of the galactic plane is .01 of the polar diameter of the universe. The angle subtended by this distance at the centre of the galactic region being 1°.7, the distance of the galaxy in terms of the polar diameter is found to be .342. If we then assume with Newcomb that the polar diameter of the universe is about 6,000 light years, the distance of the galaxy is 2,052 light years.

Taking this as the distance to the central region of the galaxy, and assuming, as shown by Professor Campbell's investigation, that its nearest part is distant about 500 light years, the farthest portions will then be about 4,600 light years from the sun.

This estimate fits in well with the distance to the limits of the universe in the region just outside the Milky Way, found from its star density, and Newcomb's conclusion that the Milky Way lies partly within the space occupied by the non-galactic stars.

In a brief survey of such an extensive field it is impossible to cover the ground completely, so I have merely attempted to give a general view of that portion of it marked off for examination at the outset. Astronomers realize that problems of the universe cannot be solved in a generation; that results can only be achieved by the co-operation of the present generation with those to come; each contributing its few grains of truth, which will finally be arranged in order. The astrographic chart of the heavens, now nearing completion, is the noblest legacy which the present generation as astronomers can bequeath to future generations. In their hands, by a repetition of the work, it should be the means of giving an insight into some of the problems of nature, about which at present we can only conjecture.

This principle of co-operation, though general in science, specially exemplified in astronomy, as its history shows. Tycho Brahe, though adopting erroneous views of the solar system, provided Kepler with the accurate positions of the planets that enabled him to formulate the laws which bear his name. These, in their turn, laid the foundation of a mechanical theory of the solar system, which, as developed by Newton and his successors, has made astronomy what it is to-day, giving us an almost perfect knowledge of the motions of the bodies of the solar system. Again, the foundation of stellar astronomy may justly be said to have been laid by Bradley, who made the first accurate observations of the positions of the stars. His catalogue, re-computed by Dr. Auwers in 1882, is the basis of our knowledge of proper motions, upon which many of the modern theories of the universe are built. Astronomers of to-day are doing their share in handing down to posterity the great star map. They, in their turn may, a century hence, find it necessary to repeat the work, extending it to include stars of the smallest observable magnitude, in order to advance knowledge of the stellar universe another step towards the final goal; which probably can only be approached asymptotically, by successive approximations, each vantage point being reached by a continually increasing amount of labor.

FORT WILLIAM'S PUBLIC UTILITIES.

The annual report of the manager of Fort William's utilities for the year ended December 31st, 1912, shows that there has been a net gain of $4,025.04 in the telephone department during the year as compared with a deficit from the operation of this utility during the year of 1911 of $2,728.30

The increase in the surplus of the light department is $21,085.19, as compared with a gain of $13,309.28 during the year 1911.

The revenue and expenditure in the three utilities, light, water and telephone, are as follows:—

Water Operation.—Total revenue, $75,091.74; operation, debenture interest and sinking fund, $88,015.14; deficit, $12,923.40.

Light Operation.—Total revenue, $99,310.97; operation, debenture interest and sinking fund, $78,225.79; profit, $21,085.18.

Telephone Operation.—Total revenue, $44,684.73; operation, debenture interest and sinking fund, $40,659.69; profit, $4,025.05.

HISTORY OF THE MAIN DRAINAGE SCHEME OF LONDON, ENGLAND.

The works which have been in progress for some years past with the object of improving the London main-drainage system are now approaching completion, and, although certain additional works are to be carried out, the great schemes authorized by the London County Council in 1899 and 1903 are now in practical operation The capital expenditure on the main-drainage works of the metropolis was £6,824,877 up to March 31st, 1912, making a total expenditure of $59,264.560.

It was not until the year 1856 that steps were taken to provide for the complete interception of the sewage of the metropolis and for its discharge into the river below London instead of within the boundaries of the City. The scheme then adopted on the advice of Sir Joseph Bazalgette, the chief engineer to the Metropolitan Board of Works, required eighteen years for its completion, and consisted in the construction of intercepting sewers parallel to the course of the River Thames and connected to the old main sewers. The sewers on the north side of the river terminated at Barking, eleven miles below London Bridge, and the south side sewers at Crossness, thirteen miles below London Bridge. Three such sewers, high, middle, and low-level, were provided on the north side of the river. The high-level and middle sewers converged at Old Ford and the low-level sewer at Abbey Mills, Stratford, all three being carried side by side thence to Barking on an embankment known as the northern outfall. Four main sewers were also provided on the south side of the river, converging at Deptford, and carried as one sewer, known as the southern outfall, to Crossness. The northern high-level and middle-level sewers and two of the sewers on the south side of the river drained either to Barking or to Crossness by gravitation, but pumping plant had to be provided in the case of the low-level sewers at Pimlico, Stratford, and Deptford, and these pumping stations, to which additions have been made at different periods, are still employed in the drainage scheme of the London County Council.

The completion of the Bazalgette scheme added to the old main sewers, which had been constructed at right angles to the river, a comprehensive system of parallel and outfall sewers which were of sufficient capacity to meet the needs of that period. The population of London at that time, taking the mean of the official figures in the Census of 1851 and 1861, was 2,586,000, but the plans adopted were designed for a population of 3,450,000. The dry weather flow provided for was 108 million gallons a day and 286 million gallons of rainfall, but the discharging capacity of the sewers was made much larger than this quantity in view of the fluctuations in the rate of flow. The old sewers, which discharged directly into the Thames, were utilized as storm overflows, and their employment for this purpose had the effect of relieving the floodings which had previously taken place in times of heavy rainfall.

At the outset the sewage was discharged into the river from both the northern and the southern outfalls without any artificial treatment whatever, and, indeed, it was not until the year 1891 that the precipitation works at Crossness were completed, the works at Barking having been finished two years before. The chemical treatment of London sewage is, however, still in the experimental stage, and, of course, the question is not so urgent in the case of the metropolis, where the discharge is into a large river with great tidal capacity, as in that of inland towns discharging into small streams. To safeguard the future, however, the London County Council have acquired an additional area of 750 acres at the outfalls in anticipation of the further treatment of London sewage by bacterial or other methods. Sir Maurice Fitzmaurice, the late chief engineer to the Council, in a report made shortly before his retirement, expressed the opinion that the further purification of London sewage will not be necessary for some years, but that meanwhile experience in sewage purification elsewhere should be carefully watched.

The Metropolitan Board of Works was superseded by the London County Council in 1889, and, though the need for fresh works had been recognized, it was not until ten years later that the plans for the extension of the drainage works now completed were definitely formulated. The need for additional sewers arose not from any defects in the old scheme, but from the operation of perfectly natural causes. The population of two and a half millions on which the original drainage plans were based was mainly on the north bank of the Thames, the population of the south side at that time being only 691,761. The rapid inrease of the population during recent years, particularly on the south side of the Thames, and the substitution of houses and streets for fields and arable land, not only increased the volume of sewage, but swelled the amount of rain flowing into the sewers. Relief works, therefore, became necessary, and the construction of the additional sewers and works was put in hand in 1901, no fewer than twenty-four main contracts, exclusive of contracts for machinery, having been placed for this work.

The additional sewers which have been provided on the north side of the Thames bring the total of additional sewers, other than storm relief sewers, constructed on the north side of the river up to a length of about forty-four miles.

The additional drainage works on the south bank of the Thames bring the aggregate up to about thirty-three miles of new southern sewers.

The Method of Construction.—The construction of the new sewers has presented greater difficulties than those which had to be met in the carrying out of the original scheme. The area covered by buildings is now much larger, and the number of pipes laid underground and the existence of a large mileage of tube railways made the selection of the routes of the sewers a subject needing careful consideration. On the north side of the river a good deal of the excavation was in the London clay. On some sections the Greathead shield method of driving was adopted, and in places where water-bearing ballast was encountered, as in the case of the length of new low-level sewer westward from Trafalgar Square, it was necessary to work under air pressure. This sewer is carried under the Metropolitan District, and East London Railways, and over the newer "tube" lines. Different strata were met with on the south side of the river. The new southern high-level sewer is mainly in chalk and ballast. The new low-level sewer from Battersea to Deptford lies for a portion of its length in waterlogged sands and gravels, and here also it was necessary to work under pressure, and to employ, as for certain sections on the north side of the river, bolted iron ring construction. On these lengths liquid grouting applied under pressure was used to form a solid backing, and the ironwork was lined with 3 to 1 concrete and the invert faced with blue bricks.

In addition to the new lengths of sewers, about ten miles of storm relief sewers have been constructed. It is now proposed to carry out extensive works for the relief of Holloway, and North London generally, and also of the area in the valleys of the rivers Wandle and Graveney and other parts of South London. The total length of main intercepting and storm sewers taken over from the Metropolitan Board of Works was about 283 miles, and the length of the County Council additions, which are principally large main sewers, is about eighty-seven miles. The length of local sewers

draining into the main system is not accurately known, but there is generally a sewer in every street, and the total length of the streets is about 2,200 miles.

Pumping Stations.—The total discharging capacity of the outfalls and storm water pumping stations is 2,171,000,000 gallons in twenty-four hours. Considerable additions have recently been made to the pumping station plant at Abbey Mills and at Crossness, and additional storm water pumping stations have been erected at Chelsea on the north side of the river, and at Battersea and Shad Thames on the south side. A new engine-house is also being provided at Crossness. Of the eleven pumping stations now in operation the five principal ones, in which the motive power is steam, are continually employed in lifting sewage, although at three of them the plant can also be used to pump storm water direct into the river. The total indicated horse-power of these five steam plants is between 5,000 and 6,000, and the gross capacity 460,000 gallons a minute. The dead lift ranges from 19 ft. to 41 ft. The duty of the other six stations, where gas-driven plant has been installed, is to pump storm water into the river at times of excessive rain. The total indicated horse-power of the plant is between 8,000 and 9,000, and the capacity 300,000 gallons a minute. The average dead lift is between 12 ft. and 20 ft. In addition, large quantities can be discharged by the storm relief sewers, which act by gravitation, though the amount cannot be accurately estimated.

The first proposals for the new works were made in 1891 by the late Sir Benjamin Baker and Sir Alexander Binnie, the latter then chief engineer to the Council. The final scheme was laid before the Council by Sir Alexander Binnie in 1899, and was then approved. The greater part of the works, with additions and modifications, and also the scheme for flood relief works, were designed and carried out under the superintendence of Sir Maurice Fitzmaurice, late chief engineer, and are being completed by his successor, Mr. G. W. Humphreys. Mr. J. E. Worth, the district engineer, has had general charge of the works on the north side of the river, and Mr. R. M. Gloyne has acted in a similar capacity on the south side. Mr. H. M. Rounthwaite has been responsible for the mechanical work.

ELECTRIC PROPULSION FOR CANADIAN SHIP.

The electrical system of ship propulsion advocated by Mr. Henry N. Mavor, of Glasgow, will be tried for the first time in a merchant vessel in the oil-engined ship Tynemouth, launched at Middlesbrough, England, last week. The only vessels of this type so far are the small experimental craft Electric Arc, with which Mr. Mavor carried out trials of his transmission gear on the Clyde, and a collier for the United States navy. The Tynemouth, which is 250 ft. long and of 2,400 tons deadweight on fresh water, has been built for the Montreal Transportation Company, and is intended for cargo service on the Canadian Lakes.

For propelling purposes she will have two Diesel engines, each developing 300 b.h.p., and between them and the propeller there will be interposed Mr. Mavor's electrical gear, which is being manufactured at the works of his firm in Glasgow. This gear is designed to allow the Diesel engines to run at a constant high speed generating electricity, and at the same time to permit the use of a slow-moving propeller of coarse pitch, reversing, stopping, and starting being carried out independently of the prime mover. For efficient service on the Canadian lakes a large propeller running at not more than 800 r.p.m. is wanted, and so far it has been found possible to meet this requirement only with reciprocating steam engines.

ELECTROLYSIS FROM STRAY ELECTRIC CURRENTS.

By A. F. Ganz.

(Continued from page 588 of last issue.)

While relief from serious electrolysis can at times be obtained by such special measures as insulating pipe coverings or insulating joints, it must be understood that all remedial measures should have for their first aim the reduction of the drop in potential in the rails to a minimum, because this removes the cause of the trouble. The first and most important step necessary to accomplish this is to maintain the rails perfectly bonded, so that the rails themselves form continuous electrical conductors. The next important step is to limit the radius from the power station to which

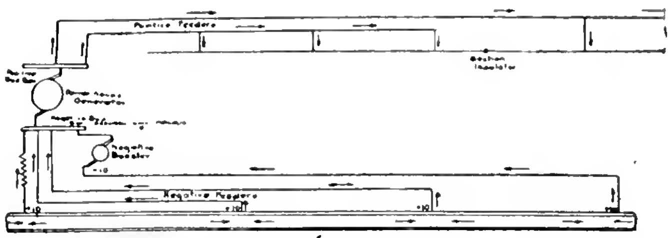


Fig. 17.—Single-Trolley Railway with Insulated Return Feeders and Negative Booster, Showing Path of Currents and Assumed Rail Potentials.

the station supplies electric power, so that current does not have to be returned from excessive lengths of rail lines to any one power station. This is usually accomplished in practice by supplying power to electric railways from distributed substations. The next step is to remove the current from the rails wherever there is concentration of current by means of insulated return feeders connecting from the rails at these points to the power station. In order that such insulated return feeders should be most efficient in reducing drop in potential in grounded rails these feeders should be proportioned for equal drop, so that the rails at all points where

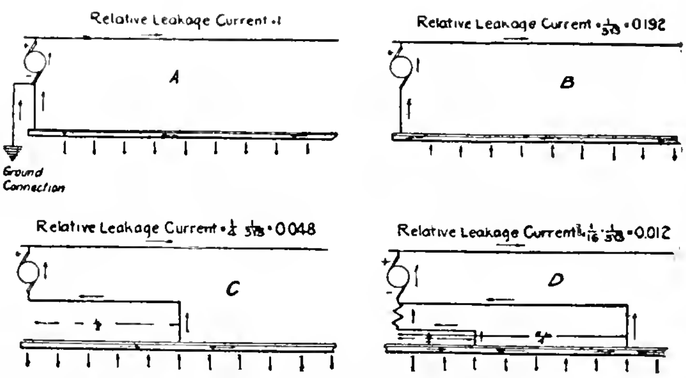

Fig. 18.—Relative Leakage Currents with Various Return Circuit Conditions.

return feeders are connected are maintained at substantially the same potential under average load conditions. This also requires that the rails immediately in front of the power station must not be connected directly to the negative bus-bar, unless a resistance corresponding to the average resistance of the return feeders is connected in this circuit. Where it is necessary to bring current back from a distant point in the rails it is sometimes more economical to employ a negative booster in series with this return feeder rather than make this feeder of such large cross-section as would be re-

quired to maintain the distant point in the rails at the same potential as the nearer connection points. With this system part of the voltage drop is actually removed from the rails and transferred to the insulated return feeders from which current cannot leak to ground.

An illustration of such an insulated return feeder system, proportioned for equal drop, is shown in Fig. 17. In this illustration it is assumed that the negative bus-bar is at zero potential and that the return feeder connection points on the rails are maintained at a potential of 10 volts with reference to the negative bus-bar. Under these circumstances there is no tendency for current to flow from the rails between points where feeders are connected to the rails. The drop of 10 volts in the return feeders has also been removed from the rails.

The possibilities in the way of reducing stray currents by means of properly proportioned insulated return feeders was clearly shown by Mr. George I. Rhodes, in a paper entitled "Some Theoretical Notes on the Reduction of Earth Currents from Electric Railway Systems by Means of Negative Feeders," published in the Transactions of the American Institute of Electrical Engineers for 1907. A few of the figures from Mr. Rhodes' paper are reproduced in Fig. 18, with diagrams illustrating the application of these figures. It will be seen that, with the negative bus-bar grounded through a ground connection of negligible resistance, in addition to being connected to the rails at the power station, the greatest amount of stray current is produced, which is assumed unity for purpose of comparison. This is illustrated by Diagram A, Fig. 18. Disconnecting the negative bus-bar from ground connections at the station, but not from rails, reduces stray currents to one-fifth their former value, as illustrated by Diagram B of Fig. 18. Disconnecting the negative bus-bar from ground connections and from the rails at the power station, and returning the current by means of one insulated return feeder from the centre of the line, reduces stray currents to 5 per cent. of their former value, as illustrated by Diagram C of Fig. 18. By using two insulated return feeders with the negative bus-bar insulated, the stray currents are reduced to 1.2 per cent. of their former value, as illustrated by Diagram D of Fig. 18. It, therefore, can be seen that very great reduction of stray currents can be accomplished by insulating the negative bus-bar at the power station from ground connections and from rails, and returning the current by means of insulated return feeders.

Since power stations are usually located near the centre of load of an electric railway system, it is usual in cities to find railway lines radiating out from the power station. Where the running tracks are connected to the negative bus-bar only in the immediate neighborhood of the power station, these running tracks are depended upon alone to return current to the power station, and there is consequently always very great concentration of stray current under these circumstances in the neighborhood of the power station. Such railway lines radiating out from the power station are illustrated diagrammatically in Fig. 19. In this figure eight railway lines are assumed radiating out from the power station. In the left-hand diagram of Fig. 19 the rails of these lines are shown connected to the negative bus-bar at the power station only. It is seen that, as the result of this, all of the current used on the eight railway lines flows in the rails towards the power station. The stray currents which leak from the rails to ground also concentrate in ground and on the underground piping in the neighborhood of the railway power station, where they must return to the rails to get back to the negative bus-bar.

If this connection between the negative bus-bar and the rails at the power station were removed, and the currents returned from the rails at points near the centre of each railway line by means of insulated return feeders, as shown in the right-hand diagram of Fig. 19, this concentration of current in the neighborhood of the power station would be entirely removed. With this arrangement, the current used by each individual line would tend to flow away from the rails at points away from the centre of each line, and towards the rails near the centre of each line. It is, therefore, seen that there is only ⅓ of the current returning from the rails at any one point than there is when the rails are connected to the negative bus-bar only at the power station. Further, the total stray current through ground with the conditions shown in the right-hand diagram will be only ¼ of the total

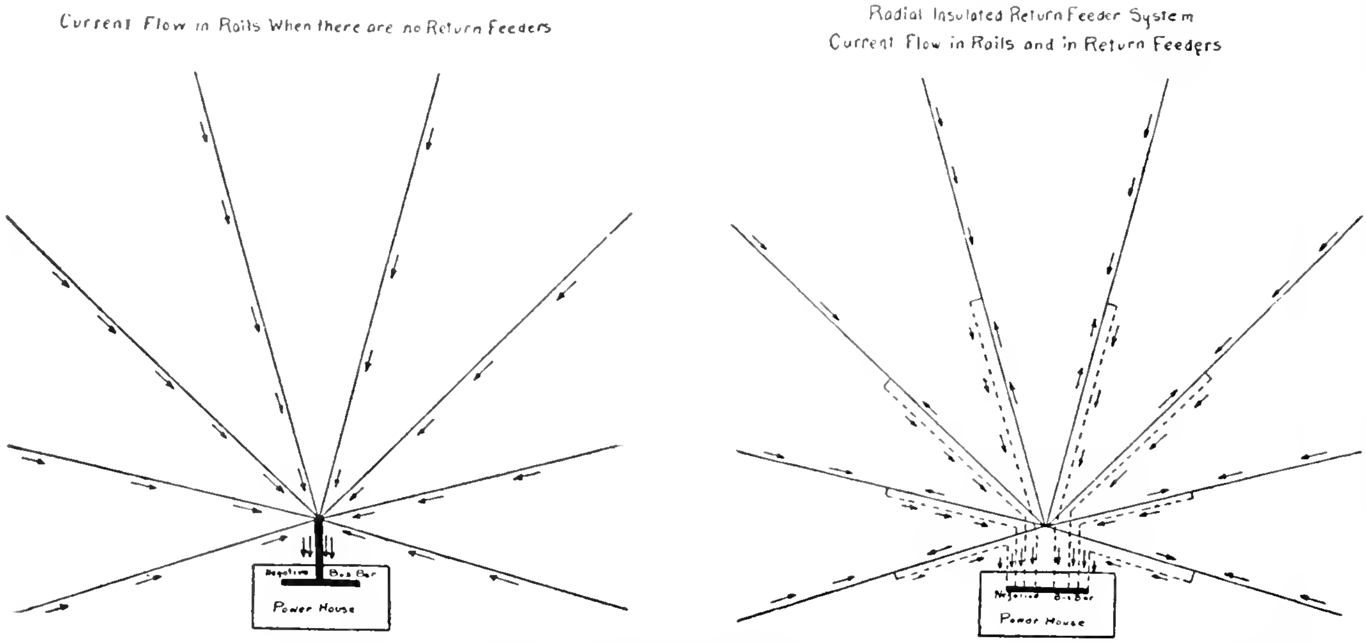

Fig. 19.—Showing Trolley Lines Radiating from Power Station With or Without Insulating Return Feeders and Showing Path of Return Currents.

stray current with the conditions of the left-hand diagram, assuming similar soil conditions, so that at any one point the danger from electrolysis will be 1/32 of what it is in the neighborhood of the power station with the first arrangement. As a matter of practice, however, the actual reduction is very much greater, because the return feeder connection points on the rails can be chosen so as to be located where the ground is high and dry, and consequently of high resistance, while the railway power station is generally located near water, where the ground is wet and of low resistance. Instead of connecting one insulated return feeder to the middle point of every line, as indicated in Fig. 19, a number of such feeders may be connected to a number of properly selected points in every line. In this way the drop in the rails, and consequently also the stray current produced, can be reduced to any desired value. In many cases the benefit to be derived at comparatively small cost from insulated return feeders with negative bus-bar insulated is much greater than above indicated. This is particularly true when the power house is at one side of a main network of tracks and connected to it only by a single branch line. To connect the negative bus-bar to the tracks of this single branch at the power house means concentrating the major part of the track drop within a short distance of the power station. In such case, the insulation of the negative bus-bar, and the use of insulated return feeders to the central rail network, will at once take the greater part of the drop out of contact with ground. This will eliminate the greater part of the cause of the trouble, as well as enormously reduce the concentration of the remaining stray current in the positive district. Thus the advantage gained by insulating the negative bus-bar is often very much greater than that indicated for the typical case above described.

The reduction of drop in potential in rails, for the purpose of minimizing electrolysis, is the basis for various regulations and ordinances which have been enacted for the purpose of protecting underground metallic structures from electrolysis. For example, the well-known English Board of Trade Regulations limit the maximum allowable potential difference between any two points in the rails to 7 volts. In Germany, a joint committee, representing the electric railway, gas and water interests, has adopted a regulation limiting the average allowable potential difference between any two points in the rails to 2.5 volts within a district encircling the urban district by a radial distance of 2 kilometers. Beyond this circle, the average potential drop in the rails must not exceed 1 volt per kilometer.

Where railway return circuit improvements have been made, to such an extent that there are no longer any excessive drops in the grounded rails, it is generally found that stray currents on underground pipes are reduced to small and often negligible amounts. Where, however, stray currents which are considered too large for safety are still found on such underground pipes after the railway return circuit has been thoroughly improved, then it is frequently possible and feasible to apply one or more of the other remedial measures, such as insulating joints in the pipes to take care of the small remaining stray current. Such other remedial measures, as bonding or insulating joints in pipes must, however, never be applied unless the railway return circuit has been improved sufficiently to eliminate all excessive drops in the grounded rails.

Summary and Conclusions.—Experience shows that where there is serious trouble from electrolysis caused by large stray currents leaking from street railways, the bulk of this trouble is due to defective rail bonding, to ground connections from the negative bus-bar, and to lack of return feeders to bring current back from the rails to the power station. While stray currents can only be entirely eliminated by insulating the return circuit by the use of a double trolley, either overhead or in conduit, it is nevertheless a fact, which is not generally appreciated, that where large stray currents exist, due to the above causes, these can always be reduced to a small fraction of their present value by removing all ground connections of the negative bus-bar and installing insulated return feeders proportioned for equal drop from radially disposed points in the track system located at some distance from the power station. By this method the rails are drained of current, and any desired part of the voltage drop can be removed from the rails and transferred to insulated conductors from which currents cannot leak. In Europe such radial insulated return feeders, for bringing current back from the rails to the power station, are made necessary by regulations limiting the allowable drop in voltage in the rails; and, in most cases, such installations of insulated return feeders have substantially removed serious trouble from electrolysis. This system of minimizing stray currents by means of radially disposed insulated return feeders has also been installed in a number of American cities, and the method is becoming recognized by railway engineers as by far the best for minimizing stray currents. This system, in fact, removes the root of the trouble, by draining the rails of current and removing voltage drop from the rails and thus preventing substantial leakage of current through ground, and is, therefore, correct in principle. The railroad companies frequently object to this system, claiming that it is prohibitively expensive. This is certainly not the case, as is evidenced by the fact that the method is in general use in Europe and in a number of American cities to-day. The fact is that in many electric railways there is practically no installation of negative feeders, and that the railway companies are often not willing to install even a moderate amount of return feeder copper. A mistake is often made in confusing the radial insulated return feeder system with paralleling the rails with copper. Where the negative bus-bar is connected to the rails at the power station, and these rails are paralleled with copper feeders, the drop in the rails is only reduced in the proportion that the conductivity of the return circuit is increased, but no part of the drop is actually removed from the grounded rails. The amount of copper paralleling the rails that would be required to reduce stray currents to a negligible amount would in all large systems be absolutely prohibitive. This, however, is not the case with the radial insulated return feeder system. With the latter system any desired reduction in rail drop and consequently in the amount of stray current, can be secured, independent of the amount of copper installed, the amount of copper being determined by the allowable drop or power loss in the return circuit. In order to effectively install and maintain an adequate return feeder system that will reduce stray currents on underground piping systems to reasonably small values, it is essential that the pipe-owning companies should co-operate with the railway companies by affording them access to their pipes for making necessary measurements, etc. After a railway company has installed a reasonable and fair return circuit, it sometimes also happens that it is desirable to eliminate any remaining current on pipes by the use of properly located insulating joints. Under these circumstances the pipe-owning companies should be willing to co-operate with the railway company in the installation of such joints.

It is the author's firm conviction that such remedial measures as pipe drainage or insulating pipe joints should be used (if at all) only as a final measure and never until the return circuit of the railway has been improved so that only small amounts of stray current remain on the underground structures.

Table for Determining Current Flow on Iron Pipes from Millivolt Drop Along Continuous Length of Pipe.
Computed by Albert F. Ganz, M.E.

L = Distance between contacts, feet.
E = Instrument reading, millivolts.
K = Constant from table.

Current flow, amperes = $\frac{KE}{L}$

Wires must not span joint.

Discussion.

The President—Gentlemen, you have listened to a splendid lecture on an important scientific subject, delivered in a manner that has made it simple and comprehensible, and by a master mind. I will ask Mr. Gould to open the discussion.

Mr. Gould—Mr. President, our troubles in Boston from electrolysis seem to be disappearing. Looking over our records for the last four years, I find we have only had an average of one case of electrolysis on mains and three on services, 1909 to 1912. That means the cases that have been brought to our attention as distinct ones. Of course, we may have had damages to our pipes through corrosion, which did not have the other electrical indications. If you had asked me a month ago whether we had had any trouble, I should have said, "Practically none"; but last month in one of our suburban districts where the electric railroad is not a part of the Boston Elevated System, a service pipe was destroyed. It had been laid about 8 or 9 years. Tests showed that our pipe was an indefinite number of degrees negative to the rails; our voltmeter only registered 10 volts, and the hand came up with a thump on that side of the voltmeter. I have heard since that the engineers from the Metropolitan Water Department four or five years ago found a maximum of 90 volts in that district, but their pipes being negative to the rail, they did not worry very much about it. This service pipe was within 50 feet of the point where we tested, and was opposite the terminus of the electric road. I found afterwards that a telephone conduit passed under the service pipe at the point where it was destroyed. Undoubtedly the current went from the rails to the main, passed through the service pipe and from it to the telephone conduit, and was one of the best illustrations of that process of destroying pipes. The railroad people are investigating this, and I hope something will be done about it. One of Prof. Ganz's diagrams illustrates a trouble which we were investigating late last fall or early this winter. One of our holders, a steel tank holder, located above the surface of the ground, had a slight leakage through the bottom plates. There is a creek from the river in back of it, formerly salt water, now more or less fresh, on account of the dam of the Charles River Basin. The ground is saturated with marsh water, and, of course, there is salt in it. The power station is perhaps three-quarters of a mile above the river. We found that there was a light current passing from the pipes in the governor house to this creek. The quantity of the current we did not know. We simply made a voltmeter test in connection with the railroad officials, and up to the present time nothing else has been done to remedy the trouble. The inserting of insulating joints would be rather difficult at this point. The connecting of the pipes in governor house to plates sunk in the creek by copper wires may do some good.

Mr. C. J. R. Humphreys—I am inclined to think that after Prof. Ganz has finished a lecture on "Electrolysis" there is not very much that the rest of us can add that will be of any very great value. It is true that we did have considerable trouble in Lawrence from electrolysis four or five years ago, trouble on the sheaths of our underground electric cables and on certain of the gas services, particularly near the power plant. I called Prof. Ganz in to our aid, and he made a very thorough survey and very thorough study of all the conditions surrounding us. Some of the slides which have been thrown on the screen here to-day remind me very much of the incidents that we ran against in Lawrence; as, for instance, a current on a water main leading to a building by the water service pipe and then coming in contact with the lead sheath of an electric service, thus getting on our cables in the conduit. Such a case as that takes a good deal of time in tracing out, and I know in one of those cases the Professor had to put in a good deal of time before he found just where the current was getting out to our cable. I do not wish to speak of each particular instance, because I think they are all covered by what the Professor has said. There are certain principles, however, that seem worthy of consideration. When we first took up this matter and we were having considerable trouble with our underground electric cables, the suggestion was made to us by the trolley people that we should connect our sheaths to their return wires to their power house. The Professor and I discussed the matter thoroughly. It seemed as if that were the only remedy, but, after considering the matter, we both agreed on the proposition that we were not going to enter into partnership with the trolley company for the return of their stray currents. They had to take care of their own current; we were not going to enter into any partnership on these lines, and we held to that. Our troubles were lessened a good deal about that time by the fact that the trolley company was relaying its rails in a part of the city where we were having trouble, and we had this matter up with them. We notified them that we expected them to take care of their currents, that we were not going to do it, and in relaying their rails and trackage, they rebuilt on very substantial lines. They lessened our troubles quite a little, and then, of course, the Professor found, as I have just indicated, several cases where the current was coming on to our system, and where it could be done away with entirely or at least reduced. Now, I would like to call attention to the importance of the charts that have been shown or reproduced here, giving the record of the recording instruments, particularly the one which showed the load current for different days in the week and for different hours in the day, where you could see in the evening, as the peak load came on, it was reproduced on the coart, and in the morning and on Sundays. Now, I think that those charts are very important. The Professor has used them in Lawrence. Their importance is this, that it establishes without any doubt that it is trolley current. I do not see how you can get away from that. If you study the peculiarities of the trolley system, when the peak comes on and when it goes off, and you find those conditions reproduced on those charts, there is no use of the trolley road coming back and saying it is not its current. That is what they told us, of course, that it was our own current, not theirs, but with the system of those registering charts, and the study of the peak loads of the trolley system, you can establish that, of course, without a doubt. The only other point I wish to mention, is this: We do not seem to have now very much trouble from stray currents, but we have not stopped and said, "Well, stray currents cannot do us any harm." We have not stopped our investigations. On the contrary, all the work that we have been doing in the past in the way of survey is kept up, and the Professor visits us at least twice a year on a special trip, and during his absence, in the meanwhile, we test our electrical system along the lines which he suggests, the idea being this, and I think an important idea, to catch on to trouble just as soon as it occurs. At times we will, in this way, detect incipient trouble, and while it may not call for immediate action, we know something is going wrong. It cannot do any harm now, but it is something that has to be watched. Now, having that in mind, detecting what you might call these minor flows of current, we have points that we know will stand watching, and we do watch them, and we hope to catch the source of trouble before any serious damage is done. Electrolysis, I think, is one of those cases where "a stitch in time saves nine" by the systematic survey work carried on practically all the time.

Prof. Ganz—I would like to supplement what Mr. Humphreys has said by a few words. Electrolysis surveys do not always give a direct return for the money spent for them. Mr. Humphreys has brought out exceedingly well how they do serve to keep track of the situation. There is one other very important use of such surveys; namely, when damage results in the future they may be useful as a proof that the damage was caused by electrolysis. Very often after a pipe has been destroyed by electrolysis and has been replaced it is impossible to prove that electrolysis was the cause. Further, if a pipe owning company finds from an electrolysis survey that its piping system is endangered by electrolysis, it can notify the railway company of this fact; if then damage results in the future, the railway company cannot plead that they were not aware of the danger produced by their currents. It has also been my experience that when a railway company knows that the pipe-owning company is making electrolysis surveys, and is keeping watch on the situation, it will do at least some work towards improving the return circuit, thus reducing the danger from electrolysis.

The Secretary—I would like to ask Prof. Ganz or anyone else, if in a condition similar to this Charlestown exhibit the chemical composition of the material after it has not been destroyed but changed, can be used as a test to show whether or not the damage has been done by electrolysis or by some other corrosive agency? Most of the cases which I personally have had have been on old lines where there was a possibility of other corrosive agents, and I have asked that question several times without receiving thus far much satisfaction from the answers.

Prof. Ganz—I believe I can give a satisfactory answer, namely, that you cannot tell from the appearance of a corroded wrought iron or steel pipe whether the corrosion and destruction were caused by electrolysis. In the case of cast iron a graphitic material left as the result of the corrosion usually, but not always, indicates electrolysis. If corrosion from electrolysis is going on, it is perfectly possible, however, to make a suitable electrical test which will show conclusively whether or not stray electric current is leaving the pipe and is causing the corrosion. For this purpose we use an instrument known as an earth ammeter; we place this next to the pipe and connect it to a recording instrument, and obtain a 24-hour record of the current flowing from the pipe to the surrounding soil. This record will not only show the presence of current but will also indicate whether it has railway characteristics. If such current is found leaving the pipe it is certain proof that it must produce a corresponding amount of electrolysis. A test of this kind, together with the corroded pipe affords, in my opinion, the best possible evidence that we can have a corrosion by electrolysis. The corroded pipe by itself without any connecting electrical measurements will not ordinarily serve as complete evidence.

Mr. Shattuck—I was interested to hear the Professor say that there was no way of knowing whether a pipe was absolutely damaged by electricity or from some other source. Perhaps in contradiction to that I have heard recently that a professor in, I think, Swarthmore College, had made examinations under a microscope, and he claimed that in the case of a pipe that was destroyed by electrolysis the particles of iron were magnetic or stood out just as they do around a magnet. I was wondering if the Professor had made any experiments along that line, or if that was more theoretical than it was practical. Has the legal question been touched on?

The President—No, it has not.

Mr. Shattuck—I did not hear the paper. I have been advised quite recently that the proper action to take in cases of electrolysis if your electric company is not willing to go ahead and do something, is to file a bill in equity against a continuing trespass, and you will have a pretty good chance of sustaining an action under such bill. It brings it to a head quicker than anything else, and I believe it is the best legal practice to-day. It may be of interest to some of the smaller companies.

Prof. Ganz—I agree absolutely with the suggestion of Mr. Shattuck. An attempt to secure an injunction would rarely be granted because an electric railway is a public utility, and the courts will hesitate a long while before issuing an injunction restraining them from operating. Regarding the tests suggested by the Swarthmore professor for determining whether a given corrosion was caused by electrolysis or by natural causes, I would like to say that local galvanic action can produce currents which would produce electrolysis in which case the corrosion is not due to external stray currents, and yet the corroded iron must have the same appearance as if it had been produced by stray electric current. I, therefore, do not think that much can be hoped for from this test.

SASKATCHEWAN'S BRIDGE CONSTRUCTION.

Methods that are followed in the construction of bridges by the province of Saskatchewan may not be generally known, but it is the policy of the Government to endeavor to build all small timber bridges, reinforced cement bridges and cement bridge abutments during the summer months, as this class of work can be better performed during the warmer part of the year, while the erection of the steel bridges, which vary in length from 40 to 250 feet each single span, is usually undertaken during the winter months; such arrangement gives continuity to the work, so that in no part of the year is there any cessation of the work of bridge construction.

It is almost unnecessary to remark that the bridging of streams, especially in those portions of the province which only very recently were thrown open to settlement, but which are now rapidly becoming the centres of agricultural enterprise, is of even greater importance than the construction of graded roads, because, as a rule, the average prairie trails can be travelled without difficulty with average loads, and it is to such districts that a considerable amount of the attention of the department is devoted, in order to enable the farmers in the outlying districts to market their produce. This might be described as pioneer bridge work.

Another class of bridge is that which is constructed in order to complete the links in a main road selected for improvement either by the rural municipal councils or by the board of highway commissioners, and wherever the location warrants, especially on the main roads directly leading to a market town, such structures are of a permanent or semi-permanent type.

The third class consists of those bridges built to replace older structures, which have passed their age of usefulness. Generally the bridges which replace these latter are of a permanent type, that is, of steel and concrete, and last year saw fifteen of these bridges handled in this manner. At the time of writing a few of these works are still in progress, and it is satisfactory to note that the work of construction has not been delayed at any time during the severe weather of the early part of February.

At present there are seven bridge crews on the day labor basis in the field, working continuously, which is about half the number of crews usually employed during the summer months; in addition to these are the contractors who are constructing bridges under direct contract.

HIGH-POWER GAS ENGINES FOR JAPAN.*

By Frank C. Perkins.

The arrangement of the four gas engines in the Kamata gas operated power plant in Japan is noted in the accompanying drawings of the 2,130 h.p. gas engines in the English shops of the Lilleshall Company, Limited, at Oakengates, Shropshire. From these drawings may be noted the details of construction of the cylinders and valves of these high power engines of the Nuernberg design built in English shops for the Japanese government.

The Japanese officials recently determined to electrify the line of railway between Tokio and Yokohama and it was decided to generate the energy necessary by means of gas power, a power house b ing erected for this undertaking at Kamara near Yokohama.

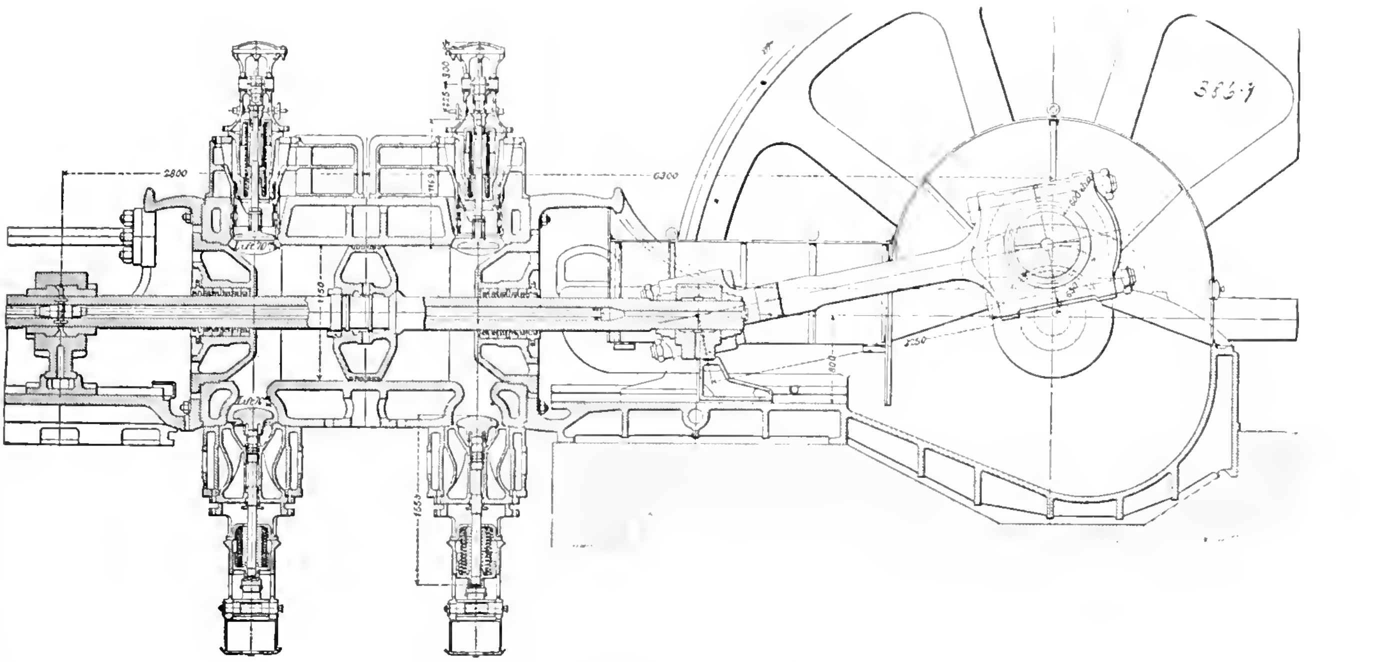
It will be noted that the station was designed to accommodate four gas engines each rated at 2.130 b.h.p. when running at 95 r.p.m. The gas producers were supplied by the Power-Gas Corporation of Stockton-on-Tees, England, and are located in a separate building. A complete plant for the recovery of the sulphate of ammonia has been provided and the sale of the sulphate, it is believed, will cover the whole cost of the fuel.

The engine house measures 166 feet in length by 90 feet in width with a forty-ton travelling crane to traverse it from end to end. It is said that the exhaust serves to provide a large part of the steam required for operating the Mond producers, into which it is necessary to pass about two tons of steam for each ton of coal gasified. There is an electric motor-driven centrifugal pumping plant provided for cooling the pistons and cylinders arranged in a pit to one side of the last engine on the right.

For starting there is a supply of compressed air under a pressure of 300 pounds per square inch provided, the two compressors being motor-driven and located near the water pumps for the piston. The compressors are cooled by a supply of water from the cylinder cooling main and deliver the air by a 2½-inch air main into receivers 48¾ inches in diameter by about 12 feet long, there being four located under the engine platforms.

On this gas engine it will be seen that the cold water enters near the hottest part of the cylinder, and is withdrawn at the coolest, and the inlet valves are nearly flush with the cylinder barrel. Each individual cylinder weighs 25 tons, and these cylinders are 1,200 mm. (47¼ in.) in diameter by 1,300 mm. (51⅛ in.) stroke. The engine was designed for a speed of 100 r.p.m. at which its output would be 2,600 to 2,500 b h.p., but at Kamata it is to run at 94 revolutions and generate 1,500 kilowatts current, this being equivalent to 2,130 b.h.p.

It will be noted that the whole of the weight of the pistons is carried by the cross-heads, thus reducing wear in the cylinder and at the blands. To this end the rods have a slight upward chamber, so that they are straight when loaded with the weight of the piston. The piston is bolted down to a conical seat by a fine threaded nut, the nut beds into the piston, and by means of a rubber joint makes a perfectly water-tight connection when screwed home.



Details of Cylinder and Valves of 2,130 H.P. Engine.

The supply of cooling water for the piston is conveyed through the interior of the piston rod, to which water connections of the swinging link type are provided at the centre cross-heads. At the central cross-head each rod has screwed on to it a cap, the swelled ends of which fit into a recess bored in the cross-heads, which is made in two parts, the upper forming a keep, which is firmly bolted to the lower. The water supply enters the rods by pipe connection which straddle the cross-head proper.

It will be observed that the junction piece between the cylinder is open at one side, so as to give ready access to the central cross-head and its water connections; and symmetry is secured by reinforcing this open side by a stout steel tie. The forward bed is made in two portions in order to facilitate the transport of the bed over the Japanese railways. The two portions are coupled together by link, shrunk into place, and the weight of the whole complete is 55 tons. The total engine weight, including the fly wheel, is 400 tons. The connecting rod is of the marine type. Forced lubrica-

*Abstract from The Gas Engine.

tion is provided for the crank pin which is 600 mm. (23⅝ in.) in diameter.

The shaft at the fly wheel seating has a diameter of 820 mm. (32¼ in.). The front cross-head is of nickel steel with the small end pins forged solid with it. There is secured to it a cast iron slipper lined with white metal and this is secured in such a way that the cross-head proper can readily be lifted clear and the piston withdrawn for examination or repair.

In the construction of this gas engine Siemens-Martin steel is used for the crank shaft, the main bearings for which have four part brasses of steel lined with white metal, and these are also arranged with forced lubrication. The glands are packed with cast iron rings turned slightly smaller than the rod, and split. Each is backed by a floating metallic packing kept tight by springs and the glands are lubricated by oil, supplied by forced feed lubricators.

It will be seen that the valves are operated by eccentrics mounted on the side shaft, and which is made in two parts coupled together by gearing, and in the gear box provision is made for the gears which drive the governor. The latter being provided with a speed regulator.

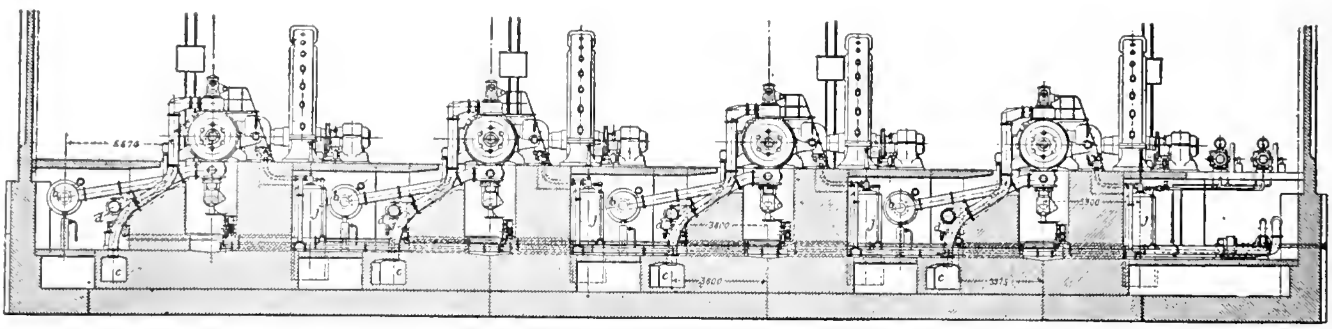
The side shaft runs in ring lubricated bearings and the inlet valves are mounted on the top of the cylinder. The eccentric rod from the side shaft is coupled to the upper of a pair of "rolling" levers, as shown, and between the two is a sliding block, the position of which is regulated by the governor.

the supply going to these. Each water outlet is fitted with a regulating cock and a thermometer, so that the supply to each part can be adjusted with great nicety, and water economized. A single large cock is provided on the supply pipe, by which the water can be shut off when the engine is stopped and the regulating cocks do not, therefore, require to be touched.

It is said that the supply of water is at the rate of about 8 gallons per b.h.p. hour, and the temperature rises from 60 degrees to 105 degrees Fahr. Cooling towers are provided by the use of which the actual loss of water is reduced to 2 pounds per b.h.p. hour. The ignition system is unique, as each cylinder is provided with three low-tension ignition plugs, operated by small electromagnets and the current supply is taken from storage batteries.

It is of interest to note that the engine is started by compressed air, admitted through independent ports, with valves which are operated by the side shafts. To each engine is coupled a 1,500-kw. alternator having its pole pieces mounted direct on the rim of the fly wheel, which was constructed by the Lilleshall Company, its weight being about 100 tons. The rim is compound, being cast round a dovetailed strip of soft steel, which is provided to take the magnetic flux between the poles. The kinetic energy of the wheel at the running speed of the engine is sufficient that the cyclical variation in speed at full load amounts to less than 1 in 250, it is claimed.

As to operation, it is said the cost per kilowatt is $0.046,



Showing Arrangement of Four 2,130 H.P. Engines in Power Plant, Japan.

As the block is near the fulcrum of the lower of the pair of levers, the valve has its maximum opening. A rotable sleeve fitted with ports is provided inside the valve casing and it moves with the main valve, and by twisting round the spindle of the latter the relative proportions of gas and air drawn in can be adjusted to suit the quality of the gas being supplied.

It is stated that the whole of the valves and their casing can be removed bodily on unscrewing a few nuts. The exhaust valve is operated by the same eccentric as the inlet valve immediately above it. As before, a pair of rolling levers are used to secure the desired rapidity of opening and closing, but no adjustment is required for varying the amount and time of opening, as is necessary at the inlet valve.

The valve is mounted complete in a casing independent of, and merely bolted to the cylinder. The casing is thoroughly water-cooled but the valves themselves are not, since it is found that with efficient cooling of the seats this complication is unnecessary. There are oil catchers which retain all the oil which escapes, and conduct it to a filter below the engine, and from this filter it is pumped back to the tank.

The cooling water is supplied at a pressure of about 16 pounds per square inch, but the accelerating forces to which the pistons are subject make a higher pressure necessary for

based upon the working of a 4,500-kilowatt central power station, supplying four gas engines, of 1,500 kilowatts capacity (one as a spare) direct coupled to three-phase generators, the gas plant consisting of three units, of 2,500 kilowatts capacity each (one as a spare); the plant working continuously at a 60 per cent load factor:

$$\frac{4{,}500 \times 60 \times 24 \times 365}{100} = 23{,}652{,}000 \text{ kw. hours per annum.}$$

It is maintained that the two generator sets would be capable at full load of coping with the load, but for the purpose of the estimate, and to get a fairer idea of the running cost, three engines have been assumed to be working. The consumption of gas per b.h.p. is taken at 106 cubic feet or 156 cubic feet per kilowatt hour (half load consumption).

It is held that the total cost of about ½ cent per kilowatt hour includes interest and depreciation, and is based upon the engine running at about half load. The cost of sulphuric acid has been taken at double what it can be bought in England to allow for the freight in Japan. Ammonium sulphate plays an important part as a manure in agriculture, and this was one of the main reasons in deciding the Japanese government to install a gas plant, and thus support their farmers without having recourse to foreign manures.

WATER TREATED WITH CHLORITE OF LIME AGAINST TYPHOID FEVER AND ITS EFFECT UPON VEGETATION.

During typhoid epidemics the water supply of cities is temporarily treated with hypochlorite of lime in order to destroy the active typhoid bacilli in the water and thus prevent the spreading of this disease by means of impure water.

Coincidentally with this practice, nurserymen and others using this treated water for their greenhouse and other plants, stated that they noticed a peculiar failing in the vigor of their plants, and thus were anxious to obtain advice whether this water may be injurious to plant life. Considering the great germicidal properties of this preparation, it was thought probable that injury might also result to higher plants from its use.

For this purpose the Dominion Chemist, Mr. F. T. Shutt, M.A., and Mr. H. T. Gussow, Dominion Botanist, began a series of experiments in February, 1911, which were continued with a view of disclosing any facts bearing on the subject.

They obtained a number of plants which were suspected to be failing in health owing to their being treated with chlorinated water. Three plants of carnations and three of Hybrid roses of this kind were subjected to the following treatment:—

1. Potted into new soil, watered as required with snow water only.

2. Potted into new soil, watered as required with chlorinated water (0.26 p.p.m. available chlorine).

3. Potted into new soil, watered as required with chlorinated water, but boiled for fifteen minutes.

4. Potted into new soil, watered as required with chlorinated water plus 1 lb. of soot per 3 gallons of water.

5. Roses grown on the farm used as check plants treated in the same manner with chlorinated water.

The plants were very carefully watched and kept under the same condition of temperature and culture. After three months had elapsed no difference whatever could be noticed in any of the plants. The roses blossomed freely throughout, the carnations, however, hardly recovered, having been transplanted while practically in flower. The check plants subjected to the different modes of treatment showed not the slightest signs of any injury.

Another experiment was conducted to test the effect of chlorinated water on the germination of seeds. Various strengths ranging from 0.05 to 10 parts per million of available chlorine were used. Six varieties of wheat were employed, the seed being soaked in the freshly made-up solutions, and an equal number in distilled water. (Time 12 hours).

All samples were sown on the same day. Germination was found to be uniform throughout; no influence could be observed on the energy of generation or in the development of the young plants. Later on, a series of experiments was started with barley and oats without any sign of injury, or even retardation. The plants were grown until in flower, when the earth was washed away and the plants, root and all, were carefully dried in the air and then weighed. Although slight differences in weight between plants of the same series occurred, such did not indicate that there had been any injurious influence exerted by the chlorinated water.

Without going into further detail, Mr. Shutt and Mr. Gussow, as a result of this investigation, conclude that the water supplies, as ordinarily treated with hypochlorite of lime, have no injurious effect, direct or indirect, upon cultivated plant.

A NOTABLE OVERLOAD BOILER TEST.

A recent test of the No. 12 boiler in the plant of the Narragansett Electric Lighting Company, Providence, R.I., produced for eight hours very nearly 250 per cent. of boiler rated horse-power at an over-all efficiency of boiler and grate of 73 per cent. This test, which was witnessed by James D. Andrew and Fred B. Freeman, of the Boston Elevated; Charles W. Clarke, of Stone & Webster Engineering Corporation; Messrs Arnold and Sarkey, of the Westinghouse Machine Company; M. Alpern, of the American Engineering Company; H. O. Breaker, of the B. F. Sturtevant Company; B. F. Allen, of Westinghouse-Church-Kerr & Company; Mr. Brown, of the Foster Superheater Company; Wm. Pastell, superintendent of the power station of the Rhode Island Company, and M W. Kern, of the Narragansett Electric Lighting Company, was for the purpose of determining the capacity of a Riley self-dumping, underfeed stoker of five retorts, which had been placed under the boiler.

The boiler, which was twelve years old, is a B. & W., 12 tubes high, 18 tubes wide, and 16 tubes long. No special effort was made to prepare it for this test. As a matter of fact, its companion boiler in the group of two was cold. The boiler was of such a size that a stoker of 7 retorts could have been installed under it, which would have resulted in the burning of more fuel and a considerable increase in the capacity obtained. As the stoker is of the self-dumping type, working automatically, there was not a periodic dumping which is a necessary feature of the other types, hence the steadiness of the steam pressure (174.1 lbs. average) and other operating conditions. The fire appeared to be in the same condition from one end of the test to the other, all clinker being broken up automatically during its process of formation, and the boiler was kept on the regular line for some hours after the test.

The total amount of coal consumed was 25,450 pounds, or an average of 3,181 pounds per hour. The water fed amounted to 251,170 pounds, or an average of 31,396 pounds per hour, thus giving an evaporation of 9.87 pounds of water for each pound of coal. The water was fed at a temperature of 196 deg. F., and the equivalent water evaporated per hour from and at 212 deg. F. was 33,437 pounds per hour, or a total of 969.2 boiler horse-power developed, which was 248.5 per cent. of builder's rating. The equivalent evaporation per pound of coal as fired thus figures out at 10.51 pounds of water, and the factor of evaporation is 1.055.

The coal analysis showed 74.13 per cent. fixed carbon; 14.95 per cent. volatile matter; 6.52 per cent. ash, and 4.40 per cent moisture. The calorimeter test showed the heating value to be 14,600 B.t.u. when dry, or 13,957 B.t.u. as fired. The coal was thoroughly consumed, as is shown by the flue gas analysis, which gave 16 per cent. CO; 0.12 per cent. CO; and 2.7 per cent. oxygen

At one time during the test a piece of 4 by 6 timber was purposely dropped into the centre hopper to determine the effect upon the stoker. This timber, of course, blocked the plunger in that hopper and sheared the safety pin located on the connecting rod. The plunger was then automatically withdrawn from the stoker upon the return stoker of the connecting rod and left at its outermost position. Upon the removal of the obstruction and the insertion of the new pin, all of which was done without stopping the stoker, operation was resumed as if nothing had happened. Of course, however, the feed of coal into the middle retort was interrupted until the adjustment had been made. The horse-power used by the blower was determined as 20, while 1.4 horse-power was used to operate the stoker. Separate motors were used to drive blower and stoker.

EFFECTS OF ELECTRIC CURRENTS ON CONCRETE.

By E. B. Rosa, Burton McCollum and O. S. Peters.

This paper deals with the results of an extended series of experiments carried out at the United States Bureau of Standards during the past two years. The investigations consisted of three parts, as follows: (1) Laboratory investigations relating to the nature and cause of the phenomena produced by the passage of electric current through concrete; (2) investigations in the field with a view of establishing the probable extent of the danger in practice, and the circumstances under which the trouble is most likely to occur; (3) a study of the various possible means of mitigating trouble from this source leading to specific recommendations. The experiments were for the most part carried out on cylindrical specimens six inches in diameter and eight inches high with an electrode, usually of iron or other metal, imbedded in the centre, serving as either an anode or cathode in different cases. These specimens were immersed in water in jars surrounded by a sheet-iron electrode, which served as the other terminal.

Anode Effects.—The tests were carried out with a great variety of voltages, ranging from 2 volts to 115 volts, with the imbedded electrode anode. On the higher voltages, which included all cases having more than about fifteen volts per specimen, there was exhibited the familiar phenomenon of cracking of the concrete and rapid corrosion of the imbedded iron, most specimens cracking within twenty-four hours under a current flow of from 0.5 to 0.8 ampere-hour.

On the low-voltage specimens, however, where the voltages ranged from 2 to 15 volts, very different results were obtained. At the outset of the investigation 90 specimens containing iron electrodes were placed in circuit on fifteen volts and watched for a period of seven and a half months. At the end of that time a number were broken open, the amount of corrosion determined, and the general condition of the concrete noted. A most conspicuous feature of the results of this test—and a very surprising one in view of the results previously obtained at higher voltages—is the fact that cracking almost universally failed to occur. Of the 90 specimens under test only three had cracked at the end of seven and a half months, and these were shown to be abnormal specimens. In practically all cases, also, there was no appreciable corrosion of the iron. It is important to note that the total number of ampère-hours per square inch of imbedded electrode surface in the case of the low-voltage specimens is considerably larger than for the high-voltage specimens, the former averaging 2.6 ampère hours and the latter only 0.83 ampère-hour. It is evident, therefore, that the quantity of electricity that passes through the specimen does not alone determine the amount of damage that it may do, but that the rate at which the current flows is also an important factor. Moreover, it is evident from these observations that the rate at which damage occurs decreases with decrease in voltage much more rapidly when the voltage is lower, since in the present instance a reduction of voltage to one-fourth of the value used in the high-voltage tests enabled the specimens to run with little or no damage for a period over 200 times as long as was required to destroy the specimens in the higher voltage. It has been shown that this difference in the effect of high and low voltages is fundamentally due to a difference in temperature. So long as the heating effect of the current is insufficient to raise the temperature of the specimen to about 45° or 50° Centigrade, little or no corrosion results, but if the current is strong enough to raise the temperature materially above that point, rapid corrosion sets in.

Cathode Effects.—When the imbedded electrodes are made cathode, different effects are produced. In this case there is no tendency for the iron to corrode, and the conclusion has been largely accepted that when the current flows from the concrete to the iron no effects were produced. It was found, however, that after such specimens had been in circuit for several months with the iron cathode the bond between the iron and the concrete was practically destroyed. On laying the specimens open it was found that the entire region surrounding the cathode for a distance of one-sixteenth to one-fourth of an inch from the surface of the metal was considerably darker in appearance than the main body of the concrete, and was very soft. The cement here could be shaved off with a knife like soft soapstone.

Experiments with concrete containing no reinforcing material showed that the flow of comparatively heavy currents through the concrete produced no appreciable effect on its mechanical properties. The effects noted above are, therefore, solely electrode effects, and the softening of the cement at the cathode is attributed to the concentration of sodium and potassium hydroxide near the surface of the cathode, and it is this that causes the softening of the cement. The cracking of the concrete when the iron is anode is due to formation of oxide of iron, and the swelling action thus gives rise to a mechanical pressure which cracks the specimen. The pressure thus prduced was measured in several instances and was found to reach values of over 3,700 pounds to the square inch.

Rise of Resistance of Concrete.—It was found that in all cases the resistance of the concrete rose greatly, due to the passage of electric current, the rise being greater in anode specimens than in cathode specimens, the former showing an average increase of 137 times the original value at the end of seven and a half months, and the latter showing an average increase of fourteen times the original resistance at the end of about the same period.

The addition of a small quantity of salt to the concrete produced very marked effects. Two or three per cent. of salt added to the water used in mixing the concrete caused the anode specimen to be destroyed very quickly, even on very low voltages, because of rapid corrosion of the iron, and also greatly increased the rate at which the softening of the cement at the cathode progressed. The addition of salt likewise reduces the initial resistance of the concrete, and, more important still, prevents the rise of resistance which otherwise takes place under the influence of the electric current.

In discussing the possibilities of trouble from electrolysis in concrete structures under practical conditions, it is pointed out that, while the dangers from this source have often been greatly exaggerated, the possibilities of trouble are nevertheless sufficient to make precautionary measures necessary under many circumstances. A number of possible precautionary measures are discussed in the last section of the paper.

That development is proceeding steadily all over the lower mainland and on Vancouver Island is shown by the announced policy of extension and expansion of the British Columbia Telephone Company. Officials of the company toured Vancouver Island last week and will make extensions to outside plant in nearly all of the exchanges on the Island. Improvements have been in progress in Victoria for a couple of years past, and large works are now in hand there. The fact that the smaller exchanges throughout the Island show growth indicates a settlement on the agricultural areas, something that is badly needed in this province. In Point Grey, the company is expending much money, and plans this year to have telephones all over the Burrard peninsula.

CONTENTS OF THIS ISSUE.

"MODERN METHODS OF ILLUMINATION."

Modern methods of illumination have had a great deal of study and investigation devoted to them during the last few years. It has been well justified by the admirable results obtained, and has been brought about not merely for commercial reasons, but from the necessity of protecting human eyesight from the intensity of illumination due to modern inventions in the field of illumination.

On another page of this issue will be found an article dealing with the use of Tungsten lamps in mills and factories. It is the invention and commercial advantages of such methods of illumination as the metal filament electric lamp that has helped along and adds stimulus to the solving of illuminating problems.

Whether the light was close to the eyes or in the line of vision or not was a matter of no great moment. In the successive improvements from the tallow candle through the oil lamp, yellow flame gas jet, incandescent gas mantle, and carbon filament electric lamp the conditions as to color and brilliancy were such that the available brilliancy was too small to cause discomfort, and, within limits which were fixed in the case of combustion lights by annoyance from heat, smell, and fumes, and in the case of carbon lamps by convenience of location, the source of the light was brought as close to the work to be performed as possible. The change from the more or less "mellow" light of carbon lamps to the intense white brilliancy of incandescent metal filaments had the immediate effect of raising complaints against the new light on the score of hurt to the eyes. The greatly improved efficiency as regards current consumption was not to be neglected, however, so that means were taken to mitigate the cause of complaint by placing the lights further away from the working plane. This movement had a retrograde aspect, however, since it necessitated the use of lamps of higher candle power, though still of greater efficiency, to maintain the previous intensity of illumination. The next step, therefore, was to search for means by which to reproduce this intensity without using lamps of higher power than before, and the increased use of enamelled tin and opal conical shades was the result. This has gone on till we find that in the lighting of shops, offices, warehouses, showrooms, and passages all that is wanted in the majority of cases is that a predetermined intensity of illumination shall be available at the working plane with a minimum current consumption and cost of installation. Shades and globes, on the other hand, are largely used in hotel lounges, restaurants, and private houses, where the sacrifice by diffusion of a small amount of the available light need not be considered and where appearance must not be sacrificed to first cost.

THE PANAMA CANAL AND ITS INFLUENCE ON THE COAST CITIES OF BRITISH COLUMBIA.

Nothing has probably occurred in the recent history of the continent of America calculated to exercise a more profound influence on the future of British Columbian cities than the coming opening of the Panama Canal. Much has been said in this regard by many writers. It would seem that the benefits flowing to the cities through the opening to traffic of this gateway will be very much as the people decide to make them.

They have a very strong strategical position. They have a country teeming with natural resources. They

have the best natural harbors on the whole stretch of coast line running from Panama to Alaska—and it might be thought, in consequence of this, that their future is so well assured that they could afford to cease troubling about it. It would be the part of wisdom, however, for them to leave nothing undone to take full advantage of the splendid opportunities which are about to present themselves through the opening to traffic of the Panama Canal.

Capt. Logan, of Victoria, speaking on the subject, inclines to the conviction that three things will probably happen immediately on the opening of the Panama Canal which will have a direct effect upon the ports of British Columbia. First, there will be an increase in the volume of shipping; second, there will be an influx of immigration to the Province; third, there will be a material increase in the permanent population of the cities.

One of the first effects on Vancouver Island of the opening of the Canal will be to stimulate renewed agitation for the bridging of Seymour Narrows. No one disputes that, given all-rail connection with the mainland, Victoria would occupy a position of superiority and advantage over the other cities of the North Pacific seaboard.

In respect to immigrants, the continuous journey without change in a voyage of less than a month's duration and at a fare which will be practically little more than is now charged for passage across the Atlantic will assuredly result in bringing West a number of those now in the United Kingdom and elsewhere in Europe who will be drawn by the opportunities. It will be probably more comfortable for the emigrant from Europe whose destination is the Prairie Provinces to travel via the Canal than across the Atlantic direct and then by rail west. There will follow a stimulus to Island and mainland development, but this will not take the most advantageous course unless they have formulated some policy before the influx begins.

Victoria and the Island of Vancouver have a great future, and if the bridging of Seymour Narrows is ever accomplished Vancouver and the other cities on the coast will have a hard time to hold their own in rivalry.

TRANSMISSION OF ELECTRIC ENERGY IN BULK UNDER WATER.

The transmission of electric energy in bulk by cable under water is a problem that has not yet been seriously tackled, but the first sign of a possible new era is seen in the project now in course of realization for sending electric current from the Trollhattan Waterfall, in Sweden, to Denmark by submarine cable. The occasion for it has arisen through the need on the part of the municipality of Copenhagen for a reliable source of energy for its electric tramways. This point was forced on the municipality's notice at the time of the coal strike in Great Britain, as they have been accustomed to obtaining a fuel supply from there.

It would now seem that only the consent of the Swedish Government is needed and a contract will be entered into for the construction of a high-voltage transmission line from the Waterfall Trollhattan, in Sweden, along the coast for 160 miles and then by submarine cable across a ten-mile sound to Elsinore, on the Danish island of Zeeland. A central distributing station will be erected at Elsinore, and a current will be transmitted to Copenhagen, fifty miles south, and to other industrial centres of the island.

THE NEW CAPITAL OF AUSTRALIA AND ITS PUBLIC BUILDINGS.

Canadian architects, in common with members of the profession in all parts of the world, will shortly be given an opportunity to compete in the designing of the principal public buildings for Canberra, the capital city of Australia, which was officially designated a few weeks ago. Canadian Trade Commissioner D. H. Ross has forwarded to Ottawa from Melbourne, Australia, a report on the subject, in which he states that the sites for the principal buildings of the capital having been determined, it is proposed that competitive designs shall be invited from all parts of the world. The building sequence contemplates practically no interruption, and among the first public structures to rear themselves on the site will be the governor-general's residence, courts of justice, police buildings and jail, administrative offices, military depot and offices, schools, observatory, medical and hospital buildings, railway station, prime minister's residence, accommodation for members of parliament, post-office, printing office and town hall. Other buildings will also be erected, such as a state house and educational institutions.

ELECTRIC AND STEAM WINDING.

Electric winding at the gold mines on the Rand has made rapid strides during the last two years in spite of the fact that coal is both plentiful and cheap. Several of the large mining concerns have their own generating plants, but as a rule the power is purchased from the Victoria Falls and Transvaal Power Company. Those companies which generate their own power mostly use the Ward-Leonard system and those which use purchased power employ the three-phase system, but there are prominent exceptions.

In the Brakpan Mines, for example, both methods are at work, the three-phase generally for winding rock and the Ward-Leonard principally for men and materials. About 50,000 tons of ore are hoisted monthly from a depth of 3,825 ft.

On the whole, the costs for stores, repairs, and maintenance of electric hoists inside the engine-house are considered to be lower than those for a similar sized steam plant. The highest efficiency of coal at the lowest selling price for the best local quality would enable 816 ft. tons to be lifted by steam at a cost of a penny. In the instance quoted the electric winders lifted 260,727 tons of rock from a depth of 3,825 ft., and handled men and tools amounting to 40 per cent. of the total work performed, for a power cost of $20,000, and the work done in rock hoisting alone works out at 960 ft. tons for one penny as compared with 816 ft. tons for steam.

A better illustration may perhaps be afforded by taking the actual steam and electrical power costs at the Bantjes Consolidated Mines. At the No. 1 shaft a Grant-Ritchie winding plant is installed with 6 ft. drums driven through single-reduction gear ratio 127 to 42 by a 600 horse-power three-phase induction motor working at 2,000 volts and 362 r.p.m. From October, 1911, to July, 1912, inclusive, this particular hoist raised 133,684 tons and used 231,392 units, the units consumed per ton hoisted averaging 1.73, or, at 1.1234c. per unit, 1.944c. per ton hoisted. With spares, renewals, and labor the total cost was 2.32c. per ton. These engines were run by steam from November, 1910, to April, 1911, and, including coal, wages, and maintenance charges, the average cost was $498.52 per month. The average cost for electrical winding, including maintenance charges, from May to September was $363 a month.

ABSTRACT OF REPORT ON THE CITY OF TORONTO TRAFFIC REQUIREMENTS.

The report of B. J. Arnold, of Chicago, and T. W. Moyes, of Toronto, who were engaged by the latter city to examine into and report on street railway traffic requirements, has now been made public. The report itself has been finished for some time, but the city had refused to make its contents public.

The report as boiled down reads:—

Car congestion can be overcome by re-routing.

Overcrowding can be largely eliminated by the use of extra cars.

Track mileage has increased only 2.4 per cent., while the population increased 9 per cent.

The Toronto Railway Company spends 57.46 per cent. of gross income on operating and other expenses, while other companies spend 70 per cent.

Toronto spends less than 1 per cent. in maintenance of track and roadway. Chicago spends 2.27 per cent.

Thirty-five per cent. of the company's track should be rebuilt.

Faster service should be provided and trailers eliminated.

Equipment is so operated as to produce 28 cents per car mile, while expenses are 13 cents.

Toronto has 113 miles of single track. An addition of 127 miles should be made, which, with equipment, would cost $8,762,000.

Tubes are not needed at present, if better surface equipment is provided.

Motor 'busses will not meet the situation.

That the city has outgrown its transportation facilities is emphasized. They say there are few difficulties in the way of giving needed relief. Co-operation of the varied railway interests is suggested as a means of affording quick relief. "Car congestion could be overcome by re-routing a few lines in the congested district, and over-crowding could be largely eliminated by the use of extra cars during rush hours." They recommend faster time schedules, and say an improved service could be thus given without an additional car.

Cross-town lines and extensions into the outlying territory are recommended The experts are opposed to subways, which are not warranted.

Ordinarily, for a system covering an entire city under Toronto's conditions 70 per cent. of the income is required to operate and to meet the taxes and depreciation. The reports of the Toronto Railway Company for 1911 show that these items, exclusive of renewals, consumed only 57.46 per cent. of the gross incomes. This demonstrates the ability of the company to increase its service materially without sacrificing fair return from business, even if a liberal allowance is set aside for renewals.

The company's annual report to the Ontario Railway Board shows the total expenditure for maintenance to be only 8.58 per cent of the gross receipts. The average of all Chicago companies for 1910 was 8.6 per cent. But Toronto spends only .926 of 1 per cent on maintenance of track and roadway, while Chicago spends 2.27 per cent for the same purpose. The statement of the Toronto Railway Company shows no expenditure for renewals, which alone should be from 8 to 10 per cent. of the gross receipts Thirty-five per cent. of the company's tracks should be rebuilt and other improvements made. Fifteen to eighteen per cent of the gross receipts should be spent in upkeep, after the property is put in first-class operating condition.

Schedule speed of the cars should be increased, the report states, and trailers should be eliminated. The public and the crews of the cars should be more alert. Faster cars should be provided, and improved turnouts and curves installed.

The Toronto Railway Company is at present operating 113 miles of track over an area of about 10½ miles in length, east and west, by 3¾ miles in the extreme width, north and south. The business is conducted with 642 cars, 569 double-truck and single-truck motor cars and 73 trailers. The equipment is so operated as to produce 28 cents per car mile, notwithstanding the low fares, while the expenses are about 12 cents per car mile, a most favorable showing for surface lines in any city.

The total cost of the proposed additions to the present system for 127 miles of new track, 600 pay-as-you-enter cars, additional car-houses, sub-stations and other equipments, is estimated at about $8,762,000.

If the civic car lines and those of the Toronto Railway Company are to continue to be operated under more than one management until 1921, a terminal in the business section of the city is recommended. "Without proper outlets," the report states, "isolated lines generally lead a precarious existence and prove a disappointment."

The estimate of the cost of a complete new surface and subway system is $10,473,000. The present traffic would not warrant this expenditure, the experts state, but they admit that a subway system might be a financial success if the growth of population north of St. Clair Avenue and Danforth Avenue increased greatly.

The following radial lines are recommended: Yonge Street, Cottingham Street to the north end of the new city limits, with temporary arrangements for transfers with the Metropolitan Railway; double tracks to Eglinton Avenue this year, with double rails owing to the difference in gauge.

Davenport Road from St. Clair Avenue and Keele Street to Dupont and Bathurst Streets, to be double-tracked in 1916.

Dundas Street, from Keele Street to Lambton, double track in 1914.

Weston Road, from Dundas Street to Mount Dennis (Eglinton Avenue), 1916.

Lake Shore Road, as a terminal and outlet for lines west of Sunnyside Avenue, to be operated to the Humber as part of the King Street line as soon as the gauges are equalized.

Kingston Road, from King Street north-east and east to the city limits, to be double-tracked by 1916.

WORK ON ATLANTIC DIVISION OF C.P.R.

Word comes that Mr. W. Downie, general superintendent of the Atlantic division of the C.P.R., has issued the following statement in respect to the expenditure on maintenance of way, bridges, rails, culverts and the like on the main line from Megantic to St. John, not counting branches for the two years, 1911-12:—

	Capital.	Maintenance.	Total.
1911	$220,142	$528,985	$749,127
1912	348,417	674,663	1,023,081
Total for two years			$1,772,208

Mr. Downie pointed out the large yearly increase in these expenditures and the big total reached last year as compared with the expenditure in 1911, and said that during the last nine years the entire division from Megantic to St. John had been relaid with 80 to 85-lb. rails, while the line was ballasted throughout. Every wooden bridge taken out and replaced by steel with masonry or concrete and wooden culverts were replaced by concrete ones.

PANAMA WATER SUPPLY.

The committee, consisting of Mr. H. H. Rousseau, chairman; H. O. Cole, George M. Wells, James T. B. Bowles, and Louis Ernst, appointed to consider plans and make recommendations for a permanent water supply for the Pacific end of the canal, has submitted its report, and same has been approved by the chairman.

The plans contemplate the continued use of the Rio Grande reservoir, and the increasing of its capacity by raising the dam to elevation 265 feet, or 27 feet above the present crest. It is believed that with the increased capacity the reservoir will supply at least 6,000,000 gallons of water a day, except in years of minimum rainfall, such as 1888 and 1912.

It is further proposed to use the Camacho reservoir as an auxiliary supply. The surface of the water in this reservoir at high level is 100 feet above that in the Rio Grande, so that a gravity flow between the two reservoirs could be maintained by means of a pipe line, or by a small concrete-lined aqueduct laid around the main hills for a distance of about 13,000 feet. It is estimated that about 1,500,000 gallons of water a day would be added to the Rio Grande supply in this manner. Before final adoption of the Camacho pipe line, the committee recommended that an estimate be made of the cost of laying the line, as compared with an estimate of the cost of pumping the same amount of water a day from Gatun Lake.

Assuming that 7,500,000 gallons of water a day might be obtained from the above sources, the committee turned its attention to the matter of a further supply. The possibility of procuring water from the Pedro Miguel and Cocoli Rivers was discussed, but the idea was abandoned in favor of Gatun Lake.

The plan of pumping water from the lake at a point on the west side of the canal, just north of the entrance to Pedro Miguel Locks, would involve the installation and operation of electrically driven pumps, but it would provide an absolutely certain supply during all months of the year, and would take care of a consumption far beyond the present estimate.

The consumption will probably not be less than 8,000,000 gallons a day when the canal opens. In view of future expansion, the committee recommended that the maximum normal supply should not be less than 12,000,000 gallons a day, and that the purification plant, pump station, and accessories be designed not only for that amount, but that provision be made for their future extension and enlargement without interference with the continuity of the supply.

The experience gained during the past six years, and particularly during the last year of the Agua Clara plant at Gatun, conclusively indicated in the minds of the members of the committee that the stream waters of the Isthmus yield readily to aeration, and aluminum sulphate treatment, followed by sedimentation and sand filtration. Heretofore, little attention has been given to the bacterial efficiency of the treatment, because practically all the water used for drinking purposes has been taken from uninhabited watersheds, with very little risk from contamination. In the proposed new water supply, the use of Gatun Lake water makes the matter of bacterial efficiency an important one. It is believed that a properly designed purification plant, with aeration and sedimentation, using aluminum sulphate, followed by rapid sand filtration, will take care of such water, but to provide against the possible contingency of pathogenic bacteria getting into the filtered water mains, it is proposed to use a bleaching agent—hypochlorite of lime—in addition to the aluminum sulphate, this agent to be used only when the daily analysis of the water indicates the presence of B. coli. The cost of this treatment would be small.

The committee considered the relative merits of pressure filters, as compared with the rapid mechanical gravity filters. It was shown that the first cost would be less, and that there would be an approximate saving in head of from nine to 15 feet by the adoption of the mechanical gravity type. It was further shown that filters of this type are rapidly supplanting those of the pressure type. The committee recommended their adoption.

It was believed that in using both the present 20-inch and 16-inch mains from the Rio Grand reservoir into Panama, the best plan would be to install pumps on these lines just south of the proposed purification plant to act as "boosters" to the gravity head available, these pumps to be designed to deliver the maximum supply south of Corozal, with a terminal pressure practically zero at some point near the present low level reservoir at Ancon. At the latter point, it is proposed to install a second "booster" station with pumps directly on the main to lift water to the low and high level reservoirs. This line would be by-passed, so that the pumps could pump directly into the mains fed from the above reservoirs. All pumps and stations would also be by-passed, so that in case of trouble to the pumps, the head due to gravity would deliver some water through the mains. The "booster" pumps will obviate the necessity of laying an additional feeder line, at least until the estimate of 12,000,000 gallons of water a day is exceeded. "Booster" station No. 1 would probably be located on the west bank of the canal, north of Pedro Miguel Locks, and would contain the supplementary pumps furnishing Gatun Lake water to the purification plant. "Booster" station No. 2 would likely be situated at some point near the present pump station at Ancon.

At the present time there are at Ancon two high pressure reservoirs, each 1,000,000 gallons capacity, one situated on the east side of Ancon Hill at an elevation of 295 feet above sea level, and the other on a knoll back of Hotel Tivoli, at an elevation of 138 feet. The committee was of the opinion that additional high pressure storage is necessary, and recommended the construction of a new 1,500,000-gallon reservoir immediately adjacent and connected to the present high level reservoir on Ancon Hill.

There is installed in the masonry of the emergency dam at the north end of Pedro Miguel Locks, a 24-inch diameter cast iron main carrying the water from the Rio Grande across the locks. It was the opinion of the committee that, as a measure of safety, and to provide for a possible future increase, an additional cast iron main, 30 inches in diameter, should be carried across the locks to a junction with the present 16-inch and 20-inch water mains.

The committee investigated a number of sites with reference to the location of the proposed purification plant, but refrained from making a recommendation, except that the plant be situated at the best point available on the west side of the canal, north of Pedro Miguel Locks.

The committee recommended that such work be done as will make the old 16-inch main continuous from the Rio Grand reservoir to Panama, and that it be cross-connected to the new 20-inch main throughout its length.

In view of the fact that the elevation of the purification plant, the size of the "booster" pumps, and finally the quantity of water that the mains may be expected to deliver in Panama depends on the correct value of the coefficient of friction for these lines, the committee recommended that friction tests be made, and that the results obtained be adopted in connection with the computations involved in the design of the different plants.

THE PROBLEM OF THE STEEL RAIL.

The problem of the steel rail is, as it has been for years, a very real one. In this connection we present herewith an extract from a paper by A. J. Beaton, M.Inst.C.E., which appeared in the South African Railway Magazine. Mr. Beaton, in his paper, presents data secured from the United States, Great Britain and South Africa. The article is one which it will well repay those interested to read. We quote from Mr. Beaton's article as follows:

There is a considerable divergence of opinion among railway engineers, and many confused ideas exist, as to the average life of a steel rail. An expert authority has estimated that an 80lb. rail will be worn out after carrying about 250,000,000 tons of traffic. The railways of the world have a mileage of about 642,000 miles, and yet for strictly replacement purposes hardly two million tons of steel rails are used annually, although American rail mills are producing about four million tons of rails per annum, the bulk of these, however, being for new railway construction.

In New York State one rail breaks every year for each 3.8 miles of single track, or about one rail in every 1,220. The number of rail failures, covering 83 American railroads during the year 1910, according to the Committee on Rail, of the American Railway Engineering Society, ranged from 0 to 1,129 rails per 10,000 tons of new rail. On the continent of Europe one rail in from 1,350 to 2,000 breaks every year, while on the South African Railways for the year 1911, 301 rail breakages were reported, being about one rail in every 25 miles, or one rail failure in about every 8,600. The South African Railway figures do not embrace the rail failures in station yards and sidings.

The bulk of the breakages in America were of the 85lb. and 90lb. section, and included several 90lb. titanium rails.

None of the breakages have been attributed to inherent weakness of the rails, the failures being alleged to unusual strains induced by such severe conditions "as the action of flat wheels, defective counterbalanced wheels, wheels out of round, defective track, poor ballast and improper track fastenings," while the recent increase in axle loads and high speeds have considerably reduced the time factor for the reversal of stresses under the wheel loads, thereby inflicting more punishment on the rail than what would have taken place under lighter axle loads and lower speeds.

The rails on the American railways were of recent rolling, and the majority of the failures occurred during the three coldest months of the year, the month of Janu-

ary accounting for 1,645 breakages out of a total of 3,951 for the year. In June only 52 failures were reported. On the London and North-Western Railway, England, the number of rail failures in 1898 were twice as many during the winter months as in summer.

Life of Rails.—The life of a rail is greatly dependent on the nature of its composition, its geographical position, the type of rolling stock, the volume of traffic, and the quality of ballast.

An 80lb. rail, of 5-inch section, laid in a tunnel on the New York Central and Hudson River Railroad, carried 65,000,000 tons with a loss of ⅜-inch of metal upon the head before it was removed. The loss of metal on the top of rails on all sections of the tunnel was about twice as rapid as rails in the open subjected to the same tonnage.

On exposed sections of many railways running along the sea coast, corrosion due to the action of the sea-air is very severe on steel rails and fastenings.

The discovery of an effective anti-corrosive composition will be valuable and remunerative, both to the inventor and railway companies.

It has been recorded that an 80lb. rail was in service on the Great Northern Railway, England, for 35 years. The analysis of this rail indicated a very soft rail with high phosphorus.

On lines with slow and heavy traffic the head of the rail may have less ductility with slightly greater abrasion resistance than would be permissible for lines carrying a high speed passenger service. On the other hand, rails subjected to heavy traffic and high speeds should be of the very best composition, and improved in their wearing quality, even at an enhanced price, and every effort made to arrive at the best scientific disposition of the materials so as to synchronize the life of every section of the rail.

In discussing the wear of rails on curves, Mr. Beaton states that no comprehensive reliable information has hitherto been collected on any of the South African railways, although exceptional opportunities were presented in the way

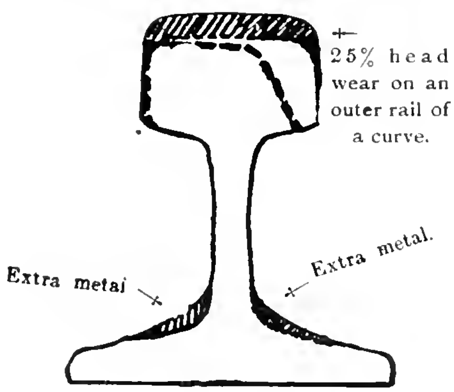

Fig. 15.

of an extraordinary abundance of sharp curvature, and consequently the scientific world has been deprived of much valuable data.

Table Showing Life in Months of 75lb. Rails, A.T.S.F.Ry.

Radii of Curves in Feet.	574	717	955	1146	1433	1910	Feet.
Outer rail . .	9	15	24	40	56	72	Months.
Inner rail . .	18	24	48	60	72	96	

Statistics are not compilations for satisfying curiosity, but should be of such practical commercial value as to enable future efforts to be directed into more successful channels, and to assist in correct deductions being arrived at. When the reliability of statistics is once assured they should

Radius	637	717	955	1433	2865	5760	gent.
Life in months . .	9	14	20	30	60	90	120

be accepted and acted upon, even if they upset one's pet theory, or clash with popular preconceived conclusions.

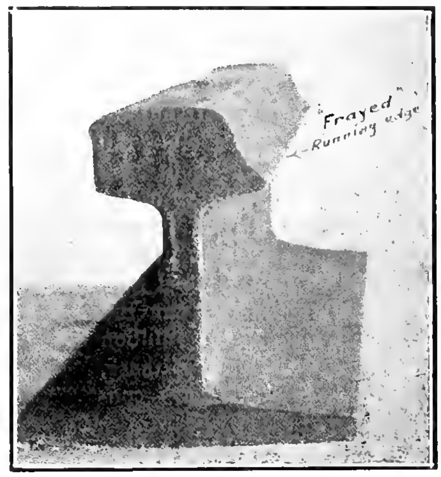

Fig. 16.

In Europe, where curvature is not so severe as in most other countries, although elaborate tests have been made in connection with determining the wear of rails due to errors in curvature, no very extensive experiments are recorded in regard to the excess wear on curves in relation to the wear on tangents.

American railways have, however, made some attempts to arrive at the relative life of rails on sharp curves and tangents. The Aitchison Topeka and Santa Fe Railway has tabulated the approximate times of removal of 75lb. rails on the sharp curves on the mountain section of their system, particulars of which are given in the above table.

Investigations made by the Pennsylvania Railway in this connection have not differentiated between the wear of the outer and inner rail, the table given above merely indicates the average wear on 100lb. rails on various radii, under heavy main life traffic.

This table corroborates the accepted axiom that the excess rail wear on a curve varies approximately as the degree of curvature

The conclusions arrived at from the experiments made on American railways are that the excess wear on a 574ft. curve will be about 230 per cent. of the rail wear on a tangent. Tests made on the Northern Pacific Railway indicate that the excess wear on a curve over that on a tangent, is a little less than one-quarter of the tangent wear per degree of the curve. It is, however, doubtful if these results will be applicable to the 3ft. 6in. gauge and the type and weight of rolling stock on the South African railways.

There are many important factors affecting the wear of rails on curves which might well claim the closer investigation of engineers on maintenance of way, and practical experience and minute inspection is the best school in which to acquire the requisite knowledge. It is a well-known fact that errors of over 8 per cent. from the true curvature re-

duces the life of a rail from one-third to one-half its natural life, had the curvature been true. Similarly, irregularity in gauge or in super-elevation have a disturbing influence on the wear of rails and on the smooth riding of the track.

The writer observed on a 12 degree (478ft. radius) curve,

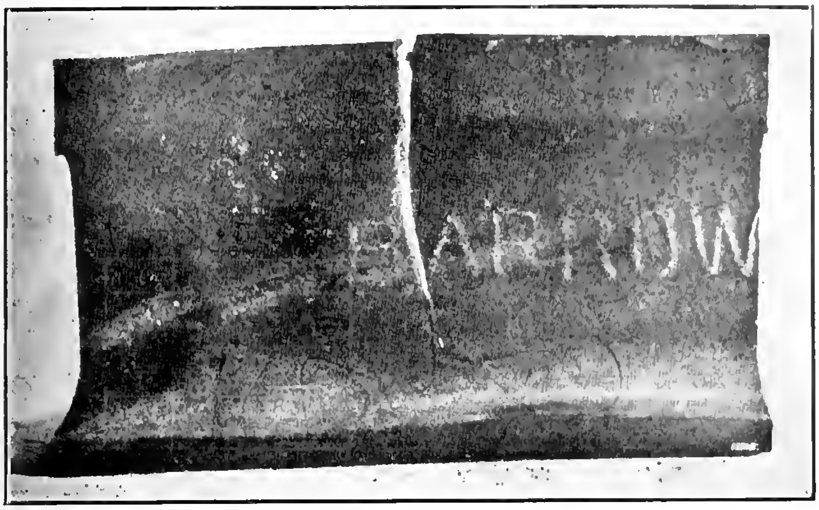

Fig. 18.

with 4 inches of super-elevation and a gauge width of 3ft. $6\frac{5}{8}$in. on an up-grade of 1 in 50 compensated, that the abrasion on the lower rail of the curve was very severe, but no side wear was apparent on the higher rail, while on a 140 deg. (410ft.) curve, with a similar super-elevation and grade, but with only a gauge width of 3ft. $6\frac{1}{2}$in., the wear on the running edge of the higher rail was very marked. On another portion of this curve, where the gauge was widened to 3ft. 7in., no side wear of either rail was observable. This points to the necessity for allowing liberal "slack to gauge" on very sharp curves, rather than increasing the super-elevation, as is sometimes practised.

On a single track railway there is the insuperable difficulty of securing the correct super-elevation for both directions of traffic, thus on a 1 in 50 down grade, on a 10-chain curve with 4 inches of super-elevation, a speed of thirty miles per hour is permissible with passenger rolling stock, but anything approaching this speed cannot be attained by an up grade passenger train, while heavy goods traffic barely reaches ten miles per hour, hence for such slow speeds only half an inch super-elevation would be required; it, therefore, becomes necessary to approximate the super-elevation to about the mean speed of the up and down trains, for if the full theoretical super-elevation demanded for the maximum permissible speed on sharp curves is adopted on a steep down grade, then undue wheel flange pressure will be exerted on the lower rail by upgrade slow trains. It would, therefore, appear as if the maximum permissible safe speed cannot be permitted on sharp curves with steep gradients.

It was the practice on the Central South African Railways to remove side-worn rails from the higher side of curves and replace them in the lower side of the curve, while in many instances, when the versed sine of a rail was not over 3 inches at the centre the rail was reversed in its original side of the curve; generally after the side wear on the head of the rail indicated a loss of from three to four pounds, the rail being finally removed from passenger lines after losing about 10 per cent. of its original weight. The average services of 60lb. rails on 150 metre curves ranged between three and four years. Unfortunately, no record was kept of the rolling tons of traffic which passed over the track.

A similar practice obtained on the Rhodesian Railways, although in Natal, owing to the rapid wear of rails on 300ft. curves and 1 in 33 grades, the practice of exchanging the rails was not adopted, but in some cases side worn rails were laid on tangents, a practice which does not give so satisfactory results as when reversed in their original position or transferred to the opposite rail in the curve.

On the Cape Government Railways curve worn rails were not exchanged, as was the custom on the other administrations.

Sections of worn rails recently removed from curves on the South African Railways are seen in Figs. 10, 11, 12 and 12a.

The table given will serve to better appreciate the value of the above sections of rails.

On some American railways 90lb. rails are removed from the main line after showing a head wear of 25 per cent. A safe practice is to remove all worn rails from passenger service lines when they show a loss on their original weight of 8 per cent. on curves and 10 per cent. on tangents, dependent, however, on certain factors of speed and traffic obtaining on particular sections. Professor Webb describes some interesting tests conducted on the Northern Pacific Railroad, regarding the wear of rails on curves. The figures obtained indicated that the rail wear is comparatively small during the first half of the life of a rail, and that the rate of wear grows in geometric ratio, especially so on sharp curves. This may possibly be due to the wear of the rail conforming to the outline of the wheel tyres, causing an acceleration of the abrasion on the running face of the rail through the close contact of the knuckle of the tyre

The average yearly loss in weight in lbs. of five rails on the outer side of a 10 degree curve (578 ft.) on the Northern Pacific Railway, extending over a period of five years, showed the following results:—

	1st year.	2nd year.	3rd year.	4th year.	5th year.
Loss in lbs. ...	10.85	9.55	7.75	11.65	16.55

The tests were made over a variety of kinds of steel, each rail having lost a little over 8 per cent. on their weight, and are described as "badly worn," yet not actually removed from the track.

Remarks.—Nos. 1 and 2 are still in the track, having done 54 months' service to date.

Nos. 3, 4 and 5 were in the track for 47 months, on higher side of curve, then turned end for end in their original side of the curve, and finally removed from the track after 17 months' service on their new running face, after a total service of 64 months.

Nos. 6 and 7 were removed from service at the end of the above periods.

Nos. 10 and 11 represent the wear on rail after a period of 215 months, but were left in the track until 1912, a total service of 240 months, but no record was kept showing the wear after final removal from the track.

Figs. 16 and 17 represent the photographs of a section of an 80lb. rail from the Boven Deviation. This rail is from a 410 ft. radius curve 1 in 70 grade. It did service in the high side of the curve for 35 months, and was then changed over to the low side, and finally removed from the track after being 17 months in the low side of the curve owing to

the excessive "fraying" of the new running edge, so clearly shown on the photographs.

A number of rails by various makers, and collected from different railways in England, showed very little deterioration or wear on the top of the rail. After a service of an average of sixteen years, and having carried an average of 100,000,000 tons, the head wear only showed a little over ¼-inch on average.—(Vide Proceedings Inst. C.E., Vol. CXXXVI.).

Fig. 21.

Forty-five per cent. of the rails on the London and North-Western Railway broke after carrying between 25,000,000 and 50,000,000 tons of traffic, while only 17 per cent. failed after carrying between 50,000,000 and 100,000,000 tons.

It is, however, very difficult to say what internal deterioration takes place in rails from "fatigue" of the metal, or what brittleness is developed by the cold hammering of the wheels; therefore, loss of weight or severe abrasion of surface cannot alone determine the limits of the usefulness of a rail. On the other hand, the Colonial maintenance engineer has not the necessary apparatus at hand to accurately determine the various factors affecting the durability of a steel rail; he must, therefore, for the present, at any rate, fix the limit of its usefulness by its loss of weight or other visible physical defects which renders it unsafe for use in the track.

In connection with the excessive wear of rails on curves, more attention might be devoted to this important matter, and it would well repay maintenance engineers to give the subject closer scrutiny and more scientific study, with the view of elucidating the relative life of a rail and its resistance to wear in varying degree of curvature, gauge, and super-elevation, as any accurate data obtained in this connection would undoubtedly form a valuable asset to track economics.

Improved Rail Section.—The first thought suggesting a remedy for excessive rail head wear is to increase the area of the metal subjected to the greatest wear, and such a proposal has been submitted for discussion by Mr. W. S. Potter, of the Manganese Steel Rail Company, New York, whose suggestion consisted of the addition of more available head metal and increasing the thickness of the base by the addition of fillets between the web and base.

The section shown in white outline, is an American 90lb. rail, the shaded areas indicate the proposed additional section which adds 15lbs to the weight of the rail, while the heavy dotted line on the head of the rail represents a loss of 25 per cent of metal on the head of a worn outer curve rail.

As side-wear on curves is much in excess of on straights, Mr. Potter's suggestion is not quite practicable, as it involves a redundance of head metal on tangents, or else necessitates having different depths of rails on curves and tangents, with the attendant objectionable joggled junction fishplates.

The additional area in the fillets of the web of Mr. Potter's rail also appear somewhat excessive, as the bulk of failures in the web originate where slots are provided in the base of the rail for spikes—presumably to stop creep—cutting notches for spikes in the edges of the flanges of a rail is not good practice, knowing how sensitive steel is to any detrimental form, of which the angular shape is the most aggravating.

South African Railways.
Table Showing Details of Grade, Wear, etc., on Sections of Worn Steel Rails.

The suggestion of increasing the area of the fillets to a small extent between the web and the base, is, however, worth further investigation, as many rails fail at these points before other sections are exhausted.

Fig. 13 shows the present prevailing 80lb. standard steel rail of American railways, with the old section of the American steel 80lb. rail super-imposed thereon in dotted lines. Fig. 14 shows the B.S.S. 80lb. rail super-imposed in dotted lines on the existing standard 80lb. rail of the American Railway Engineers' Association.

The American Railway Engineering Association has observed "a difference between rails of different mills when the sections and chemical compositions are practically the same," and has consequently deputed steel experts to determine by actual tests which of the leading steel manufacturers turn out the best rails.

The figures 18 and 21 are reproductions of photographs taken of a worn-out 78lb. rail from the Natal Main Line. Mr. Chas. G. Bateman, Assistant Superintendent of Maintenance, quotes the life history of this rail as follows:—"It was laid on straight about 1898. Removed from straight and put in high side of 500 feet radius curve at 42¼ miles, on the 6th December, 1908; taken out from high side of this curve on 2nd November, 1910, and was relaid again on the 9th of the same month for relaying low side of 300 feet radius curve at 40½ miles, 'Satan's Hole,' and broke under combined train on the 5th August, 1912, when it was scrapped. Grade 1 in 30, and trains usually negotiate this grade

fairly steadily. Loss of weight, 13 lbs. 5 ozs. per yard." This represents a loss of about 17 per cent. which is somewhat in excess of the recommended maximum.

It will, therefore, be seen how important it is to give a close and observant study to everything affecting the wear on rails, in order to effect every economy possible in connection with a unit which is far and away the most expensive constituent part of the permanent way.

Even from these meagre notes it must appear manifestly clear that a wide field of research is open to the railway engineer in connection with the problem of the steel rail, and any careful investigations of a practical or scientific nature will be welcomed as an effort to assist in solving a hitherto neglected factor which reflects so materially on the economical functions of railway engineering.

GOVERNMENT HEARING ON THE GRAND RIVER CONTROL.

On Wednesday, April 16th, at 10 a.m., a delegation received a hearing from the Ontario Government on the question of the control of the Grand River. The Government was represented by Hon. Dr. Reaume, Minister of Public Works; Hon. Mr. Duff, Minister of Agriculture; and Messrs. Pattinson, M.P.P., Mills, M.P.P., and Richardson, M.P.P.

The delegation was a large one, representatives from all the municipalities along the river, from Dunnville to Fergus, being present.

Mr. J. P. Jaffray, of Galt, the President of the Grand River Improvement Association, in presenting his argument for Government action, said that the Grand River valley ran through one of the most thickly populated sections of the province, and also one of the most important in manufacturing, agriculture, and general interests in the Dominion. He added that delegations had been approaching the Government during the past twelve years. The flood menace was constantly increasing, while the low-water flow was dwindling.

Mr. T. H. Jones, City Engineer of Brantford, spoke of the work done on the river by the Hydro-Electric Power Commission last year, and of their recommendation that this work should be continued on a more thorough scale so as to get all data and designs required. He added that the Commission should be requested to fully report on the project. He spoke of the large expense incurred by the city of Brantford (over $100,000), and flood protection was still far from satisfactory.

Mr. Kerr, of Fergus, spoke of the desirability of a Government reservation of large size on the waste land, or nearly so, of the head water areas of the Grand River.

Mr. W. H. Breithaupt presented his reasons for believing the Government should take action, and his argument is given at some length in this account, as it gives some valuable data on the Grand River.

The Hon. Dr. Reaume stated that he was strongly impressed with the urgency of the case, and would recommend Government action. He suggested that municipalities along the river should contribute a part of the funds required to carry on the investigation.

The following data on the Grand River was presented by Mr. W. H. Breithaupt, M. Inst. C.E., in the course of his address:—

Drainage area of the Grand River, 2,600 square miles, essentially the central part of the peninsula of south-western Ontario; parts of the counties of Grey, Dufferin, Perth, Oxford, Norfolk, Halton, Wentworth and Haldimand and the whole of Wellington, Waterloo and Brant. The drainage area is wide, and of largest expanse along the upper part of the river. The Conestogo branch rises also on the head plateau almost as far north as the main river.

Total fall of the river from the head plateau of its rise to its outlet into Lake Erie is over 1,100 feet.

The head water plateau was originally large swamp, probably to the extent of 400 square miles in area or more. During the last fifteen or twenty years especially this swamp area has been cleared and drained. Run-off from it is now very rapid at times of snow melting and heavy rainfall, whereas formerly it was slow and snow melting was greatly retarded. In consequence spring floods of the river have greatly increased.

Tributaries of the main river in their order from up-stream are the Conestogo from the west, the Eramosa-Speed from the east, and the Nith from the west.

Precipitation, rainfall and snowfall are not definitely known in the watershed of the Grand River. There are but few observing stations. From other stations and from partial records it appears likely that the total precipitation, rainfall and snowfall in the upper part of the watershed is 35 to 40 in. or more, whereas on the lower part, which is also narrower, the annual precipitation is somewhat less. There are no data on run-off, but it is safe to estimate that for the head-water area it amounts to 12 in. or more per annum.

There are various methods of flood control of a river. Deepening of the channel and the construction of dykes along the banks allows a large increase in the volume of the water passing. Another method is to raise the general level of the banks which are to be kept above water. All such methods are palliative only and benefit the immediate locality only. A much better method is to remove the cause of floods by impounding near the sources. It is apparent that this method is not applicable to all rivers. Certain topographical conditions are essential to its success, as also definite general conditions of the drainage area. Impounding must be at locations where a large part of the flow of the entire river can be arrested, and for a reservoir the valley must contain an extended basin with high enough banks and a reasonably narrow neck, again with high banks, for the construction of a dam.

The only possible method by which uniformity of flow or an approach to such uniformity, can be secured, is by storing surplus waters in seasons of flood and releasing them in seasons of drought. It may be stated that as a general rule a sufficient amount of storage can be artificially created in the valley of any stream to rob its floods of their destructive character, but it is equally true that the benefits to be gained will not ordinarily justify the cost.

The determining factors in the control of the flow of a river by storage are:—

(1) The flood flow of the river.

(2) The amount of sustained flow, for low-water period, that can be provided for. And further:—

(3) The cost, including the value of the area flooded as compared with the benefits to be derived.

(4) The situation of the storage basin: whether it can be placed so as to have enough contributory drainage area and at the same time properly control a sufficient length of the river to make it worth while.

(5) The character of the water to be impounded, whether it is clear or so charged with sediment that silting will unduly shorten the life of the works.

From general indications it appears that the Grand River is peculiarly well adapted for storage control, and that the required works can be carried out at a cost to make them well worth while. Before definite conclusions can be drawn, however, it is necessary that much more detailed and extensive examinations should be made.

Observation extending over many years confirms that all larger floods come primarily from the head-water area and extend the length of the river, as naturally occurs by reason of the wider expanse of this area and the greater precipitation there It is evident, therefore, that control of the yield of the head-water area will enable prevention of the destructive crest of the flood throughout the length of the river, as also reasonable maintenance of sustained flow for the whole river. Land condemnation for reservoir sites will be comparatively moderate in cost. The drainage area of the main river to the outlet of the Conestogo branch is approximately 460 square miles, while that of the Conestogo branch is approximately 330 square miles. A storage basin of sufficient size located on the main river a short distance above the outlet of the Conestogo, another smaller one on the main river above Fergus, also a considerable storage basin on the Conestogo branch as near its outlet as may be—these three basins with a total dischargeable capacity of, say, 2,500,000,000 to 3,000,000,000 cubic feet, would, it is estimated, suffice to catch the destructive part of any flood, and would have enough contributory drainage area to give a sustained flow of 400 to 500 cubic feet per second below the outlet of the Conestogo branch. Storage also on the Eramosa-Speed and on the Nith tributaries could not only materially better this result for the main river below their respective outlets, but give required flood protection to the large population centres, especially on the Speed, as well.

The definite data to be obtained are:—

Extended records of rainfall and snowfall at various points throughout the drainage area, and particularly on the head-water area.

Continuous stream-gauging at a sufficient number of points in the main river and branches to determine the run-off factor, as also rapidity of run-off.

Full topographical survey of possible storage basins and examination by test borings of dam site for each basin.

Delimitation of the upper river drainage area and of the head-water areas of the branches.

BRICK PAVEMENT SPECIFICATIONS.

The American Society of Municipal Improvement has published standard specifications for brick pavements as adopted by the society at its last annual convention. An interesting paragraph of the specifications is that the brick shall not lose of their weight more than 22 per cent. when submitted to the rattler test.

Samples of brick of uniform shape and appearance are required to be taken from each car (estimated at 10,000 brick). Brick having defects that would cull them shall not be used. Three grades of samples shall be tested—one of the softest, one of the medium and one of the hardest burned. If all of the tests overrun 22 per cent. loss, the car shall be rejected. If one or two of the tests overrun, another test of said grade or grades shall be made. Should only one of these tests overrun 22 per cent. loss, the contractor may cull said grade, provided they do not exceed 10 per cent. of the amount of the brick in the car, and deliver the balance on the improvement. Otherwise the whole car will be rejected. In order to prevent the continued shipments of inferior brick, only two cars of two separate shipments of any make of any brick will be tested. Should they fail to meet the requirements stated above, said make of brick will be rejected for this improvement.

Among the cities which permit no more than 22 per cent. loss by abrasion are Baltimore, Grand Rapids, Akron, Toledo, Newark, Philadelphia, etc. Only 21 per cent. loss is allowed by Chicago, Indianapolis, Canton and Columbus.

MODERN INDUSTRIAL LIGHTING SYSTEMS.

That the Tungsten lamp has already become the permanent standard illuminant for mills and manufacturing establishments is the opinion of Albert L. Pearson, electrical engineer, of Lockwood Greene & Co., as presented in a recent paper read before the American Society of Mechanical Engineers at the Boston Engineers' Club. The following remarks are taken from this paper:—

For certain work in which line distinction or clearness in combination with wide diffusion is the prime requisite, the mercury arc is a close competitor. One principal objection to the mercury arc, however, is the entire lack of red light waves in its spectrum. A fluorescent reflector, which will supply to a certain extent these missing red rays, makes the light more natural and at the same time less objectionable. On the other hand, the Tungsten lamp gives a nearly white light, approaching the ideal sunlight. Its high efficiency and ready adaptation to varying intensities also partly account for its adoption as a standard lighting unit.

In addition to providing a suitable form of lamp, a great deal of attention and careful study is now given to the proper arrangement of the lighting system itself. Lamps should be arranged to give uniform illumination at the working plane, avoiding shadows as far as possible, and paying particular attention to the requirements of each machine and each operation. White walls and ceilings are advantageous, and add to the effectiveness of any lighting arrangement. With modern individual drive it is possible to keep the rooms clearer of belts and shafting than with the mechanical or group drive, thus benefiting the lighting system. On account of glare, low, exposed units should, of course, be avoided wherever possible, and in places where lamps hung low down are necessary, reflectors which will entirely conceal the filaments should be used. In such cases a few lamps well placed close to the ceiling will overcome the effect of light and darkness.

The position of lamps should be carefully determined, both as to spacing and mounting height. Mr. Pearson believes that each problem must be considered by itself. He says that no general rule can be given, even for plants doing the same work, as changes in layout will greatly affect any system of illumination, but that in general the height of the lamp above the floor should be such that, with the spacing available, the lines representing the angles of maximum illumination with a given type of reflector will cross at the working plane.

The amount of light and the arrangement of lamps depends also upon the nature of the work and the character of the machines. Good lighting should provide safety for employees, better sanitary conditions, and, in many cases, better quality of work and increase in productivity. The best lighting should be provided for the most particular processes. In places where good light is not required, or where it is used for a comparatively short time, obviously it is not necessary to invest as much for this part of the equipment as in places where light is required for longer periods or is depended upon for quality in the work.

The day of working out a lighting system arbitrarily as so many watts per square foot of floor space or so many foot candles is passed. A study must be made of the conditions and a layout designed which will prove both economical and give the best illumnation. The distributing systems also should be designed to secure as good voltage regulation as possible and circuits arranged to eliminate waste of power for lighting any sections not in use.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

BOOK REVIEWS:

BOOK REVIEWS.

The Elements of Chemical Engineering. By J. Grossman, M.A., Ph.D., F.I.C., with preface by Sir William Ramsay, K.C.B., F.R.S. Cloth; second edition; 50 illustrations. Price, $1 net. Charles Griffin & Company, London, Eng.

Reviewed by J. Watson Bain, B.A.Sc.*

It is a matter of common remark that the superintendents of many of our factories are being drawn from the ranks of university graduates, and this is particularly true in the chemical industries. After a more or less lengthy apprenticeship in the laboratory and in the factory, the man with a good technical training and a sufficiency of common sense usually develops into a valuable official, and the rapidity with which this end is attained depends very largely upon the rate at which a familiarity with routine operations and apparatus is acquired. In the school or university the instruments employed are small and easily handled, while the use of glass and porcelain overcomes the difficulty of dealing with corrosive liquids. The college graduate then, on entering the manufacturing field, finds himself confronted by new problems which arise in the handling of large quantities of material, and it is here that valuable time is often lost in the endeavor to cope with changed conditions. To the chemist who finds himself in such circumstances or to the student who has not yet graduated, Dr. J. Grossman's "Elements of Chemical Engineering" will be of great assistance. Dr. Grossman has set himself to bridge the gap between the laboratory and the factory, and has produced a short treatise, which deals with the subject in a clear and interesting manner. The comparison of the simple forms of laboratory apparatus with their factory equivalents is emphasized in a novel fashion and assists materially in acquiring ideas as to the construction and uses of the latter. The author draws attention continually to the differences between an operation as carried out on a small scale in the laboratory and as executed on a large scale in the factory; such emphasis deserves particular commendation in view of the not infrequent blunders which arise from a lack of appreciation of this important distinction.

The chapter on technical research is particularly valuable to the young students and will suggest to him that manufacturing materials are not pure, that the solubilities of his ingredients are important and that careful experiment must be carried out in the devising of a factory process. The actual design cannot be treated in a volume of this size, and the student is referred to the more extended literature dealing with this phase. The fact that there is no other short treatise in English which covers the same field will make this book a welcome addition to the library of the young chemical engineer.

The illustrations are numerous and well chosen, while the author advises his readers to make a collection of catalogues and price lists.

* Associate Professor of Applied Chemistry at the University of Toronto.

Electrical Machine Design. By Alexander M. Gray, B.Sc., Assistant Professor of Electrical Engineering, McGill University, Montreal. Publishers, McGraw-Hill Book Company, 239 West 39th Street, New York. Cloth; 500 pages, with illustrations and charts. Price, $4 net.

Reviewed by J. A. Johnson.*

In the preface to this work the author states: "The study and design is of the utmost importance to all students, because only by such a study can a knowledge of the limitations of machines be acquired." A statement of this sort is very apt to be made by specialists who happen to hold professional positions. Each one seeming to believe that his own particular subject is the one really essential one. If they all were allowed to have their way students would have to devote their lives to preparing for their life work. It certainly is arguable, that engineers would do better to have a knowledge of the limitations of machines; that, in fact, the progress in design comes from the demands of those big-minded men who know nothing about the limitations of machines, but do know what they want and keep after it till somebody finds out that the so-called limitations are no limitations after all.

The book is of approximately 500 pages divided into four sections and forty-nine chapters. The four sections are respectively of direct current machinery, alternator and synchronous, polyphase, and induction motors and transformers. The method followed is, as to each section: First, the consideration of the theory of operation followed by a description of the types and forms of construction; consideration of characteristics of performance, procedure in design and typical specifications; the latter would stand considerable improvement, especially as to form. Mechanical design is not gone into except incidentally. One chapter only is devoted to the consideration of a few of the fundamental mechanical problems.

The author states that the work was compiled as a course of lectures. Its value as a text-book would seem to be confined pretty largely to the use of special students of design, as it seems rather too voluminous to find a place in the regular course for all students, except at the expense of time that

* Electrical Engineer, Ontario Power Company, Niagara Falls, Ont.

would be more profitably spent otherwise if broad-gauge, open-minded engineers rather than specialists are the object of the trade.

Building Construction and Drawing. (Elementary Course.) By Charles F. Mitchell, Lecturer on Building Construction to Regent Polytechnic, London, Eng.; Head Master of the Polytechnical School, assisted by Geo. A. Mitchell, A.R.I.B.A. Cloth; 472 pages; 7 x 4½ inches; about 1,100 illustrations; eighth edition; by D. VanNostrand & Company. Price, $1.50 net.

The book aims to give with conciseness and accuracy a statement of the principles which should govern the execution and building work. The authors wish it to be equally valuable as a guide for students engaged in building. The contents comprise of fourteen chapters including Instruction to Beginners, Brickwork, Masonry, Girders, Joints in Carpentry; Floors, Partitions, Wood Roofs, Composite Roofs, Iron and Steel Roofs; Joinery Plumbing, Slating and Tiling, Building Quantities, and Memoranda. A few exercises are included in each chapter, and the appendix contains an index and treats with the Examination Papers and Syllabus of the English Board of Education. It contains the subject matter of previous editions carefully revised and subjects not hitherto treated or emphasized are: Isometric Projection, Monolithic Brickwork, Bonding of Brick Footings, Hollow or Storm Walls, Facing Bond, Fixing Bricks, Example of Face Jointing in Masonry, Polishing of Marbles, Calculations of strengths of Timber Pillars, Expansion Joints for Girders and Trusses, Quotations from the L.C.C. General Powers Act, 1909, Prevention of Dry Rot, Relative Position of Members in a Typical Roof, Ferro-Concrete for Roof Construction, Description of Door Hinges, and the New Rules (1910) for the Admeasurement of Slating and Tiling.

The present issue is the eighty-seventh thousandth which speaks for itself as to its usefulness and appreciation by those interested in building construction.

Building Construction.—A text book on the principles and details of modern construction for the use of students and practical men (advanced and honor courses). By Charles F. Mitchell, Lecturer of Building Construction to Regent Polytechnic, London, Eng., Head Master of the Polytechnical School, assisted by Geo. A. Mitchell, A.R.I.B.A. Seventh edition revised and much enlarged; 885 pages; 800 illustrations; cloth. Price, $2.50 net.

The authors state that since the publication of the sixth edition considerable advances have been made in knowledge of building materials and methods of construction, thereby rendering it necessary to again revise and amplify and bring their book into line with current practice. Calculations have been rechecked; fresh examples added, and the text revised, and neither labor stinted nor counsel disregarded to make the new edition deserving of the approbation bestowed upon the former issues.

It contains 28 chapters. The chapter subjects are: Limes and Cements; Concrete; Asphalt; Plastering; Stones; Bricks; Tiles; Terracotta and Stoneware; Iron and Steel; Timber; Paints and Varnishes; Glass; Foundations; Brickwork; Flues; Fire-places and Tall Chimneys; Masonry; Carpentry; Half-timbered Work; Pillars; Columns and Stanchions; Graphic Statics; Girders; Fire-resisting Construction; Reinforced or Ferro-Concrete; Joinery; Stairs and Hand Rails; Sanitation Water Supply; Hot Water Apparatus and Ventilation; Electric Bells and Lighting.

The effects of the London County Council regulations in connection with skeleton framed buildings, and of those proposed to be adopted by the council with regard to buildings of reinforced concrete, have entailed the complete re-writing of the chapters dealing with these subjects, and as these regulations may serve as models of their kind it has been thought desirable to give their text in full.

Due note has also been taken of the revised report of the Royal Institute of British Architects on Reinforced Concrete, as well as of the recommendations of the District Surveyors' Association and of the recent work of the Engineering Standards Committee.

Throughout the book, the endeavor has been to describe the essential principles of good construction and to illustrate them by typical examples selected as far as possible from actual practice.

No further comment is needed on the merits of this book than the fact that with the present issue it will have reached a circulation of 52,000.

A Handbook of English for Engineers. By Wilbur Owen Sypherd, Professor of English in Delaware College. Flexible leather cover; 314 pages; 4 x 7 inches; Scott, Foresman & Company, Chicago and New York. Price, $1.50 net.

The author's aim and hope that the contents of this book should be "of practical assistance to engineers in college classes and the early years of professional life" should most certainly be fulfilled. He has apparently, in preparing the book, carefully read the available literature on the subject and been painstaking in partly compiling and selecting from same. The book should be very useful in higher engineering classes and will doubtless find a place on the shelves of many engineers.

The book contains five chapters, dealing respectively with General Problems of Engineering Writing, Mechanical Details Common to the Various Forms of Technical Writing, Business Letters, Reports, and Articles for Technical Journals.

The first chapter touches on the problems of technical writing. In the second chapter directions for the use of abbreviations, punctuation marks, capital letters, etc. To engineers desirous of strengthening their English these two chapters are likely to be most serviceable.

The third chapter, on business letters, briefly states the main principles governing successful business correspondence and supplies examples of good and bad usage. There is, however, no mention of methods of drawing special emphasis to points under consideration.

The fourth chapter contains a systematic treatment re rhetoric of engineering reports. The author discusses the general essentials of reports; then gives more fully the requirements of reports on tests, reports on inspection work, and periodical reports, with examples of each kind.

The fifth chapter deals with articles for technical journals. He divides his subject into short articles and longer articles, including under the former editorials, summaries and abstracts, book review and explanations of new inventions.

It is a book dealing with a subject important to every engineer, and which in the first efforts to become technically proficient is often sadly neglected by them. Many an engineer, capably equipped technically, is sadly handicapped for advancement in his profession by neglect of just such niceties of rhetoric as this book brings out. It would be well for those who have not given much thought to this subject to possess themselves of the book.

PUBLICATIONS RECEIVED.

Bureau of Railway Economics. Bulletin No. 45. 30 pages. Address, Washington, D.C.

Municipal Bulletin. Issued by the Ohio State Board of Health, Columbus, Ohio. Vol. 3, No. 2.

Municipal Bulletin. Issued by the Ohio State Board of Health, Columbus, Ohio. Vol. 3, No. 3.

Illuminating Engineer. Special gas centenary number. Address, 32 Victoria Street, London, S.W.

Canal Statistics for 1912. 111 pages; issued by the Department of Railways and Canals, Ottawa, Ont.

Manitoba Engineer. Published by the Engineering Society of the University of Manitoba. 80 pages.

Resources of Tennessee. April issue. Published by the State Geological Survey. Address, Nashville, Tenn.

Metallurgie. Journal published by the Society of Engineers and Industries, 20 rue Turgot, Paris, France.

Commissioner of Works' Report. Seventh report. 27 pages. Address, Department of Works Office, Toronto.

Report of Commissioner of Public Roads, State of New Jersey, year ending 1912. Cloth; 6 x 9 inches; 160 pages; illustrated

University of Wisconsin. Bulletin of summer session. 105 pages. Issued by University of Wisconsin, Matheson, Wisconsin.

American Society of Mechanical Engineers. Journal of the Society for April, 1913. Address, 29 West 39th Street, New York City.

American Institute of Electrical Engineers. Proceedings of the Society, April, 1913. Address, 33 West 39th Street, New York City.

American Society of Civil Engineers. March issue of the Proceedings of the Society. 620 pages. Apply 220 West 57th Street, New York City.

Irrigation. (Part of Part VI.). Annual report of the Department of the Interior for year 1912, together with maps. 123 pages. Address, Ottawa.

Farm Forester, by E. J. Zavitz, Professor of Forestry (Bulletin No. 209): 30 pages; issued by the Department of Agriculture, Toronto, Ontario.

American Waterworks Association. Proceedings of the 32nd Annual Convention. Apply to the Secretary, J. M. Divin, 47 State Street, Troy, N.Y.

Department of Mines. Annual report for Province of Nova Scotia, 1912. Prepared by the Commissioner of Public Works and Mines, Halifax, N.S.

Oil and Gas Wells Through Workable Coal Beds. Bulletin No. 65. By G. S. Rice and O. P. Hood. Issued by the Bureau of Mines, Washington, D.C.

Summary of Commerce and Finance of the United States for February, 1913. Issued by the Bureau of Farm and Domestic Commerce, Washington, D.C.

Conference Rulings of the Interstate Commerce Commission. Bulletin No. 6; cancels and includes Bulletin No. 5. Issued April 1, 1913, at Washington, D.C.

Review and Expenses of Steam Roads in the United States for December, 1912. Bulletin No. 49; issued by Inspector Commerce Commission, Washington, D.C.

Geographic Board of Canada. Eleventh report for year ending June, 1912. A supplement to the annual report of the Department of Marine and Fisheries, Ottawa. 240 pages.

Ignition of Mine Gases by Filaments of Incandescent Lamps. Bulletin 52. By H. H. Clark and L. Ilsley. Issued by Department of Interior, Bureau of Mines, Washington, D.C.

Patents. Illustrated official journal of patents for Great Britain, April 2, 1913. Issued by the Patent Office, Southampton Building, Chancery Lane, London, W.C Price 6d.

Patents. Illustrated official journal of patents for Great Britain, March 19, 1913. Issued by the Patent Office, Southampton Building, Chancery Lane, London, W.C. Price, 6d.

Apparatus for the Exact Analysis of Flue Gas. Technical paper No. 31. By G. A. Burrell and F. M Siebert. Issued by the Department of the Interior, Bureau of Mines, Wasbington, D.C.

Report of Board of Commissioners, Water and Lighting Department of the City of Harrisburg, Pa. Twenty-fifth annual report, for 1912. Apply, Commissioners' Office, Harrisburg, Pa.

Metal Mine Accidents in the United States for the Year 1911.—Technical Paper Number 40; 54 pages; compiled by A. H. Fay, Department of the Interior of the Bureau of Mines, Ottawa, Ont.

International Geological Congress. Second circular, Canadian edition of the programme of the coming meeting of the International Geological Congress, in Canada, summer of 1913. 45 pages. Apply to the secretary, Victoria Memorial Museum, Ottawa, Ont.

CATALOGUES RECEIVED.

Corrugated Pipe Company.—Thirty-page catalogue, 8 x 5 inches. Address, Stratford, Ont.

American Locomotive Company.—Bulletin No. 1,012. Mikado type locomotive built for Chesapeake and Ohio Railway.

Concrete in Farming Improvements.—Sixteen-page pamphlet, published by the Canada Cement Company, Montreal, Quebec.

Castings.—A reference for buyers of foundry equipment and supplies; Vol. 12, No. 1. Published by the Gardner Printing Company, Caxton Building, Cleveland, Ohio.

Chicago Giant Rock Drill, Tappet Type.—Bulletin No. 137. 16 pages; illustrated. Published by the Chicago Pneumatic Tool Company, 1010 Fisher Building, Chicago, Ill.

Chicago Giant Rock Drill, Mountings.—Bulletin No. 138. 10 pages; illustrated. Published by the Chicago Pneumatic Tool Company, 1010 Fisher Building, Chicago, Ill.

Chicago Giant Rock Drill, Appurtenances.—Bulletin No. 139. 16 pages; illustrated. Published by the Chicaga Pneumatic Tool Company, 1010 Fisher Building, Chicago, Ill.

Dolarway Pavements.—Well illustrated catalogue, 9 x 6 inches; 34 pages. Important to everyone interested in pavements. Apply, Dolarway Paving Company, Whitehall Building, New York City.

Universal Bulletins.—Published by Uuiversal Portland Cement Company. 10 pages; illustrated. Apply, Publicity Bureau of Universal Portland Cement Company, 72 West Adam Street, Chicago, Ill.

The Labor Saver.—Publication issued monthly by Green Publishing Company in the interests of the mechanical handling of material for Stephens-Adamson Manufacturing Company. Address, Aurora, Ill.

High-Grade Engineering Instruments.—Illustrated pamphlet, 8 x 5 inches; 72 pages. A very complete list with instructions as to adjustments. Published by the Hanna Manufacturing Company, Troy, N.Y.

Jeffrey Swing Hammer Pulverizer. Bulletin No. 31 L. A typical and practical machine for reducing ground limestone for agricultural purposes. Size, 9 x 6 inches; illustrated. Issued by the Jeffrey Manufacturing Company, Columbus, Ohio.

Co-operative Information Bureau, of Boston.—Bulletin No. 4, giving aims and officers of this society, organized in 1912; a voluntary association of persons and organizations for mutual assistance in the ascertainment of sources and places of information.

The Ransome Concrete Machinery Company, Dunellen, N.J., have issued a well-illustrated 80-page general catalogue covering the entire Ransome line, which includes every piece of equipment necessary in a complete concrete plant. This catalogue will be sent to anyone interested upon request. Write the nearest office of the company for a copy of the "Red Book."

A new standard price list on "Sterling" new code rubber-covered wire has been issued by the Standard Underground Cable Company, of Canada, Limited, Hamilton, Ont. The price list is in convenient and durable booklet form, printed in two colors, and gives prices on their "Sterling" wire for bases ranging from 13 to 20 cents for solid and stranded wire of all commercial sizes. Appended are explanatory notes and a list of electric wire cables and cable accessories manufactured by this company. The price list will be sent on request to the company.

Bitumen Cable and Mining Accessories.—The British Insulated and Helsby Cables, Limited, of Prescot, Lancashire, England, of whom the Canadian British Insulated Company, Limited, of Montreal, are the sole Canadian representatives, have forwarded a copy of their catalogue on bitumen cables and mining accessories. The catalogue is a most handsome one typographically, and the illustrations show very clearly the different types of cables and the many wiring accessories incidental to mining work manufactured by the company. Copies of the catalogue may be secured by addressing the Canadian British Insulated Company, Montreal.

The Engineering Works of Canada, Limited, Montreal, send us a copy of their catalogue "G," which is devoted to alternating current generators. The catalogue contains a very carefully prepared and illustrated description of the construction of these generators and will no doubt be read with a great deal of interest by electrical engineers all over Canada. These generators are built under the patents of the "Société Alsacienne de Constructions Mecaniques." The pamphlet contains 20 6 x 9 pages, and is very fully illustrated, and any reader interested may obtain a copy by addressing the Engineering Works of Canada, Limited, New Birks Building, Montreal, Que.

Strauss Direct Lift Bridge is the title of a very attractively gotten-up bulletin which we have received from the Strauss Bascule Bridge Company, of Chicago. It contains a very interesting illustrated description of the Strauss direct lift bridge which involves an application of the counterbalancing mechanism of the Strauss bascule to the vertical lift bridge. The pamphlet, which contains 22 pages, is illustrated by means of a colored half-tone and several line drawings, and no doubt bridge engineers will be interested in seeing this pamphlet, copies of which, we understand, can be secured by addressing the Strauss Bascule Bridge Company, 104 South Michigan Avenue, Chicago, Illinois.

Refined Asphalt for Municipal Paving Plants is the title of a very interesting 22-page pamphlet which we have received from the American Asphaltum & Rubber Company, of Chicago. The pamphlet contains a good deal of information concerning the qualities of asphalt as a paving material. City engineers, roadway engineers and paving contractors would do well to secure a copy, which can be done by addressing the American Asphaltum and Rubber Company, 600 Harvester Building, Chicago, Ill.; the Canadian Mineral Rubber Company, Canadian Express Building, Montreal, Que., or the Canadian Mineral Rubber Company, 503 Canada Building, Winnipeg, Man.

The Lagonda Reseating Machine.—Bulletin G 1. Illustrated pamphlet, 6 x 9 inches; describing construction and use of the Lagonda Manufacturing Company's portable carborundum wheel for removing soot and scale from the faces of caps and tube ends on boilers. These wheels are driven by either electric, water, steam or air motors and the photographs showing actual cleaning operations greatly assist in understanding the value of this reseating machine for making a steam and water-tight joint when replacing the caps on B. & W. and similar boilers after having been removed for tube cleaning purposes. Copies may be had by addressing the company at Springfield, Ohio.

Peebles Alternating Motors, Polyphase Induction Type.—Pamphlet No. 16 B. 25 pages; 8 x 10 inches. Eight different types of standard machines dealt with on pages 6 and 7 of the pamphlet. The company are always prepared to design machines to meet special conditions. A very full specification of the motors is given in the pamphlet, together with illustrations of various parts and of some of the different types of motor referred to above. In addition, outline illustrations and full lists of approximate weights and dimensions of every size which they manufacture are given, while full lists of technical data for 50 and 25-cycle motors are also given, machines being dealt with for three separate ranges of voltage from 110 up to 3,500 volts, at speeds of from 1,500 down to 150 r.p.m. Issued by Bruce Peebles & Company, Limited, Edinburgh, Scotland.

Messrs. Gent & Company, of Leicester, England, send us their catalogues Nos. 4, 5 and 6. Catalogue No. 4 is devoted to a description of their Tell-Tale clocks, designed for checking the movements of watchmen in warehouses, factories, mills, etc. Catalogue No. 5 is devoted to a description of their silent electric impulse clocks and electric turret clocks, which are suitable for public buildings of all kinds, such as fire halls, municipal buildings, railroad stations, etc. Catalogue No. 6 is devoted to their water level indicators and alarms, the object of these being to indicate and record inch by inch the variations in depth of water in distant reservoirs, wells, rivers, docks, etc. The Canadian representatives of Messrs. Gent & Company are Messrs. E. A. Mansfield & Company, P.O. Box 223, Hamilton, Ont.

Catalogue of book "Essentials of Electricals of Electricity." Text book for wiremen on electrical trades. By W. H. Timble. 271 pages; 224 figures; cloth. Price, $1.25 net. Publishers, John Wiley & Sons, New York.

Catalogue of book "Steam Engineering." By William R. King. 450 pages; 177 figures; cloth. Price, $4 net. Publishers, John Wiley & Sons, New York.

Messrs. Vickers, Limited, have been commissioned to build a Parseval airship for the Admiralty, the builders to pay royalties to the German company on every ship they build. The Admiralty are naturally anxious that all aircraft for the navy shall be built in Britain, and after the arrival of the first Parseval the remainder will be built in England.

COAST TO COAST.

Vancouver, B.C.—An engineering party of the Pacific Great Eastern Railway under the direction of S. A. Dice, has completed the final location between the Second Narrows through North Vancouver to Point Atkinson lighthouse, and is now engaged on similar work between the lighthouse and Newport at the head of Howe Sound. This is regarded as evidence of the intention of P. Welsh, the contractor, to undertake construction on the lower section without further delay. It has now been definitely established that the maximum grades between those two points will not exceed one per cent. The route will follow the shore line virtually all the way and will only be a few feet above high-water mark. Instead of winding past the Point Atkinson lighthouse the railway will cut through a natural draw east of the lighthouse, then strike Howe Sound and follow it all the way to Newport. The project of bridging several of the indentations along the coast has been abandoned and the road instead will be through a number of tunnels, one of them to be about 820 feet long, thus making several advantageous cutoffs. The construction from the lighthouse to Newport will be exceedingly heavy, as the cost of considerable of the milage, it is estimated, will be at least $100,000 a mile. The location of the line between Lillooet and the vicinity of Fort George, a distance of 290 miles, is now in progress. The work now being undertaken is on the lower section of the route north of Lillooet, actual construction on which is to be undertaken this summer. Eleven hundred men are now employed in the various camps along the route from Lillooet south along Seaton and Anderson Lakes and beyond to Pemberton Portage.

Ottawa, Ont.—Chief Engineer Bowden of the Railways and Canals Department, and Engineer Weller, who is in charge of the work on the Welland Canal, have returned from a trip to Panama, where they spent the past month studying and investigating the latest engineering developments as exemplified on the Panama Canal, with a view to applying the ideas to the new Welland undertaking. The government is anxious for the Welland to be the latest word in modern canal construction. The two engineers are starting work at once on designing the canal construction, and tenders will be called for as soon as possible. The preliminary work is already well under way, the route having been decided upon and the first surveys being also about complete. It is almost impossible for the contractors to get more than a start this year, but the next five years will see great activity along the line of the "big ditch" across the Niagara peninsula. The canal that is being planned is designed to meet future needs for a long period, and will be one of the greatest works of its kind on the continent.

Niagara Falls, Ont.—Regulation by the state of the amount of water which may be diverted from the Niagara River above the Falls on the American side for power purposes will be provided for in a bill introduced by Majority Leader Wagner, of the United States Senate. The measure, which embodied the recommendations of Attorney-General Carmody, recently submitted to the legislature by the governor in a special message, is designed to repeal practically all outstanding grants for diversion for power purposes and to limit diversions to the Niagara Falls Power Company and the Hydraulic Power Company.. If the measure becomes law, future diversions by these two companies will be restricted to 8,600 and 6,500 cubic feet per second respectively. These are the same restrictions which were contained in the Burton Act, which expired in March last. Provision will be made that the remainder, 4,400 cubic feet per second, not utilized under the Burton law, remain under the jurisdiction of the conservation commission. The bill would vest in the conservation commission authority over measurements of waters diverted and would provide severe penalties for violation.

PERSONAL.

MR. GEO. SMITH, engineer of Lindsay, Ont., has been appointed town engineer of Midland, Ont.

MR. MERVIN D. HALLMAN, of Berlin, has been appointed county road superintendent for the county of Waterloo.

MR. H. J. BOWMAN, M.Can.Soc.C.E., and partner of the firm of Bowman & Connor, consulting engineers, of Toronto and Berlin, has been appointed engineer of the county of Waterloo., Ont.

MR. E. G. AITKEN, chief geographer of the Lands Department of British Columbia, has been elected a Fellow of the Royal Geographical Society of London. Mr. Aitken, who came to the provincial service from the Geological Survey Branch at Ottawa, has had long experience in the United States and also at the Edinburgh Geographic Institute.

STEWART McPHIE, of Hamilton, Ont., has formed a partnership including B. Frank Kelly and E. H. Darling as consulting engineers. Mr. McPhie was for several years connected with the Hamilton Bridge Company. Mr. Darling is a mechanical engineer, graduate of Toronto University, and an associate member of the Canadian Society of Civil Engineers. Mr. Kelly is a member of the Ontario Association of Architects.

MR. R. A. ROSS, acting manager of the Toronto Hydro-Electric System, has made the following appointments on the Hydro staff: Percy E. Hart, as electrical engineer; J. Orr, general superintendent; George Stevenson, general inspector; Geo. Schwanger, as engineer of distribution; J. M. McNeilly, superintendent of meter department; R. J. Lee, contract agent; J. B. Kitchen, engineer of operation department, and G. Devlin, as head salesman.

MR. H. H. COUZENS, general manager and electrical engineer of the corporation of Hampstead, London, Eng., has been appointed general manager of the Toronto Hydro-Electric System. Mr. Couzens has had a wide experience in the practical work of designing and carrying out of the construction work involved in the complete installation of electrical plants, having held important positions on an ascending scale with the corporations of Taunton, Bristol, West Ham, and Hampstead. He will assume his duties in a few weeks.

A. R. KETTERSON, A.M.Can.Soc.C.E., and Associate of the Royal Technical College. Glasgow, Scotland, has been appointed assistant engineer under J. G. Sullivan of the Canadian Pacific Railway, looking after bridge works, western lines. Mr. Ketterson has been in the employ of the Canadian Pacific Railway about seven years. He commenced as field inspector on bridge work in Quebec, Ontario, Alberta and British Columbia. His next step up was the appointment as bridge draughtsman in the office of the engineer of bridges, Montreal, and his third rise was to the position of engineer, designing bridges in the same office. Mr. Ketterson left that position to come to Winnipeg.

The following engineers have been assigned to fixed districts in regards to the hydrographic work of the British Columbia government: F. W. Knewstubb, who surveyed the upper Columbia River watershed; E. Davis, who reported on the watershed of the Kootenay, west of the Selkirks, and the Slocan River watersheds; Clifford Varcoe, who mapped the

Kettle River and Arrow Lakes watersheds; O. F. D. Norrington, who surveyed the Okanagan watershed; W. R. C. Morris, who also reported on the Okanagan; J. F. Rowlands, who reported on the Nicola River watershed; W. R. Pilsworth, who surveyed the Thompson and Bonaparte Rivers.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS (TORONTO SECTION).

The sixth regular meeting of the Toronto section of the American Institute of Electrical Engineers will be held at the Engineers' Club, 96 King Street West, at 8 p.m., on Friday evening, April 25th, 1913.

Mr. E. E. F. Creighton, of the General Electric Company, Schenectady, N.Y., will address the meeting on "Electrical Protection." This address will deal with electrical disturbances and will be illustrated with numerous photographs and experiments. H. T. Case, secretary, 709 Continental Life Building, Toronto.

COMING MEETINGS.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS—Sixth regular meeting will be held at the Engineers' Club, 96 King Street W., April 25th, 1913. Secretary, H. T. Case, 709 Continental Life Building, Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, T. S. Young, 220 King Street W., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa: Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Mucklestone; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson. Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290. Meets 2nd Thursday in each month at Club Rooms, 584 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa: Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O. Box 7, St Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

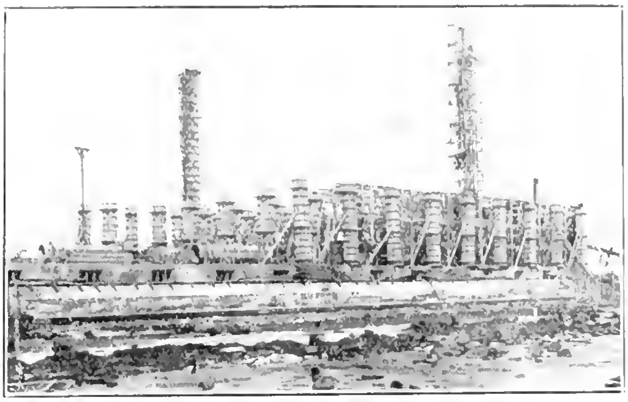
The Canadian Engineer

An Engineering Weekly

DOCK DESIGN AND CONSTRUCTION IN FORT WILLIAM AND PORT ARTHUR

By WM. C. SAMPLE.*

With an ideal location, associated with many other natural advantages, Fort William and Port Arthur, popularly known as the "Twin Cities," are destined to become one of the greatest inland ports of the American continent. Fort William and Port Arthur are separate townships, with their own municipal governments, but for all practical purposes may be considered as one port. Fort William's harbor consists chiefly of river frontage. The Kaministiquia River, popularly and for self-evident reasons, known as the "Kam," together with its offshoots, the McKellar and Mission Rivers, is the means of providing Fort William with 26 miles of land-locked harbor, with the addition of two islands by way of good measure. The natural channels of these rivers have been dredged to a depth of 30 feet; the "Kam" widened to 600 feet; the McKellar to 400 feet, and the Mission to 500 feet.



Showing Dock Wall, Taken from the Harbor.

A turning basin upwards of 1,000 feet in width is about to be made 6½ miles from the mouth of the "Kam" and this will necessitate the removal of upwards of twenty-three acres of solid earth.

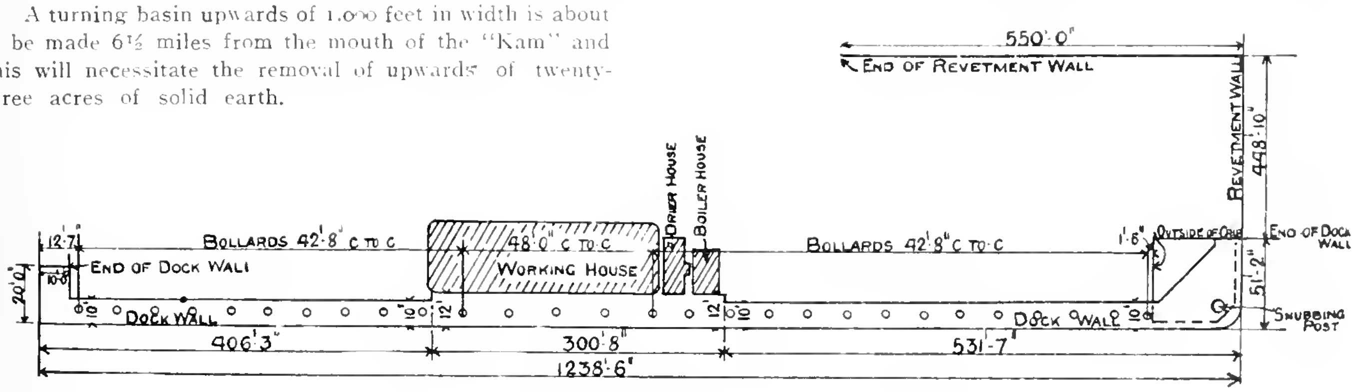


Fig. 1.—Twin City Dock Construction—Layout Plan.

Port Arthur, to whom Nature has not been quite so lavish in her gifts of water frontage, has, nevertheless, a harbor of which she is justly proud, and, furthermore, is the lucky possessor of a fine up-to-date ship-building plant (the western dry dock) where upwards of 900 men are employed, and from which many of the finest lake steamers have been turned out.

Those of my readers who may be interested in the Twin Cities harbor development might, with advantage, communicate with W. R. J. Burdett, the genial and energetic labor commissioner of Fort William, who will be pleased to supply them, as he has supplied me, with all available information.

As will be noted, Nature has provided the Twin Cities with the necessary water frontage, and it remains for the Dominion and civic authorities to take full advantage of the unique opportunities offered them of making the cities into the greatest of all lake ports. Much has been done in this direction, but more remains to be done. It behoves the responsible authorities to map out some approved system of planning and laying out their docks, and to see that all such work actually carried out is of a stable and permanent character. There is a decided tendency in these days to think only of present needs, and not of future requirements, and it is to be hoped that the authorities will avoid this error, and bear in mind that future generations will judge their work. There should be little fear of the result, however. The public men of Fort William and Port Arthur, backed up by the Dominion Government, are determined that their port will become a

*Mr. Sample is now a Consulting Engineer in practice at Fort William. Prior to coming to Fort William he occupied important Municipal Engineering positions with the Sunderland, Bootle (Liverpool) and Sheffield Corporations, and for five years acted as Designer and Estimator to the Brooklyn Grade Crossing Commission who are carrying out improvements aggregating $10,000,000 in value. He is a Charter Member of the American Society of Engineering Contractors.

port of which they will have just reason to be proud, and with this feeling paramount, their efforts are bound to prove successful.

The greater part of the dockage in the Twin Cities port is provided by the different elevator companies, who have provided excellent facilities for the speedy loading of grain-carrying steamers. The government elevator at Port Arthur, now in course of erection by the Barnett McQueen Company, for whom E. D. Casseday is chief engineer, is a notable example of this, and it is the purpose of this article to deal with the elevator dock now under construction, and of which the writer of this article was the designer.

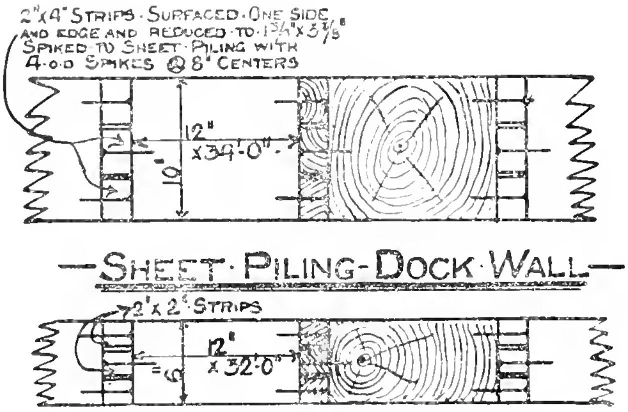

Fig. 2.—Sheet Piling Revetment Wall.

Fig. 1 shows the layout of the dock, which consists of concrete dock walls of 10 and 12 feet widths, and revetment walls of the lengths shown on the layout plan. It would, perhaps, be advisable to consider these different type walls separately, and this we will proceed to do.

Concrete Dock Walls.—A double row of piling was first driven with the centre line of the outer row, 2 feet 8 inches in from the outside of the face line of the concrete dock face, the piles being spaced 5 feet 4 inches centre to centre in both directions, and afterwards cut off at elevation 600.0, the level of mean low-water, Thunder Bay, on which the dock wall abuts. To the outside of the outer line of piles a 10-inch by 12-inch fir wale streak was bolted, the top of the wale streak being flush with the cut-off elevation of the piles. The bolting was accomplished by means of 1-inch diameter by 27-inch machine bolts at each pile-bearing. Outside of this wale streak sheet piling 10 inches by 12 inches by 34 feet was driven, every second pile being bolted to the wale streak with a ⅝-inch diameter by 24-inch machine bolt. To the sheet piling, and with the top level with the top of the sheet piling, wale streak and piles, a 12-inch by 25-pound channel iron was bolted by means of ¾-inch diameter by 27-inch machine bolts at 3 feet on centres.

The sheet piling was jetted and tapped into position, and sharpened at the bottom ends in order to ensure close driving, and form a perfectly sand-tight bulkhead. The sheet piling was furthermore tongued and grooved by building on to the edges 1¾-inch by 3⅜-inch strips of timber, obtained by surfacing one side and edge of 2-inch by 4-inch strips. The strips were spiked to the 10-inch by 12-inch sheet piling with 4 o.d. wire spikes spaced at 8 inches on centres. This construction is illustrated in Fig. 2.

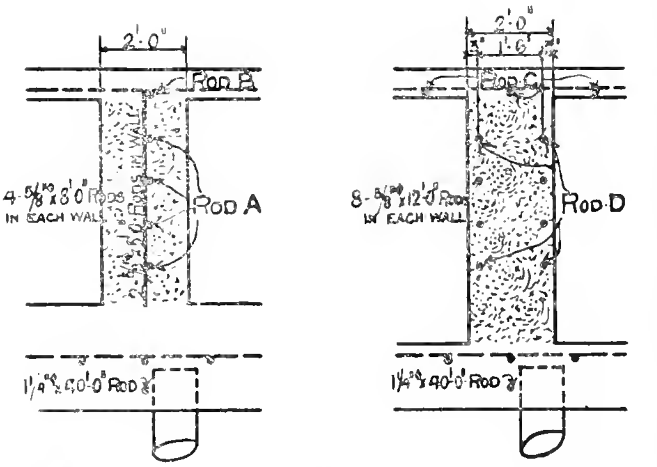
The 12-inch by 25-pound channel iron, to which reference has already been made, was punched to receive the ¾-inch diameter by 27-inch machine bolts, and also for 1¼-inch diameter anchor rods, spaced 5 feet 4 inches on centres. These anchor rods were attached to the channel by means of heavy nuts, and had a length of 40 feet with a 12-inch thread at each end. The anchor rods were passed through an anchor log, held in position by means of spur piles, and attached to same by heavy nuts and washers.

A second line of anchor rods, 1¼-inch diameter by 58 feet, placed 10 feet 8 inches on centres, connected the previously mentioned anchor log, and a second anchor log held in position by the outer row of piles, forming a trestle required in connection with the general elevator construction. These anchor rods were furnished, as in the case of the 40-foot anchor rods, with heavy nuts and washers. Spur piles were cut off at elevation 602.0.

At the outer corner of the dock wall a timber crib 48 feet by 48 feet, divided into 16 compartments by means of tie walls, was placed. The crib was built of 12-inch by 12-inch timbers, the outer walls solid and the inner walls half open. The timbers in the outer walls were halved at the corners, thus forming perfectly strong joints, whilst the inside timbers, instead of resting one upon the other, as in the outer walls, were placed to cross one another at the junction points. Fig. 8 shows the method of construction. After being built, the crib, which, it should be noted, was 23 feet in depth, was sunk to a depth of 24 feet below mean low-water datum, the elevation of the top of the crib thus being 599.0. The exterior walls were made sand-tight by having 1-inch by 6-inch battens nailed along the joints, on the inside of the walls, whilst the crib at the outer corner was cut off at an angle of 45 degrees. After the crib was sunk in place, it was filled with sand and gravel to the top, or elevation 599.0.

With the piling, sheet piling, channel and crib in position the next stage in construction was the building of the reinforced concrete dock wall.

The dock wall, as previously stated, is built in 10 and 12-foot cross sectional widths. Starting at the inshore end, adjoining a 20-foot return end, the 10-foot section is carried for a length of 406 feet 3 inches. At this point the width of the wall is increased to 12 feet, in order to join up with the



Section C C Fig. 9. Section F F

building line of the working house, which is 12 feet from the face of the dock wall. This 12-foot section continues along the frontage of the working house, drier house and boiler house, for a distance of 300 feet 8 inches. From this point the 10-foot section is carried to the crib, where, at the outshore end, it is increased to a solid mass of concrete with a face radius of 33 feet. The plans and sections clearly show the methods of construction pursued. The inshore end at the return corner was similarly strengthened by a solid block of concrete, less in bulk, naturally, than was required for the outshore corner of dock wall.

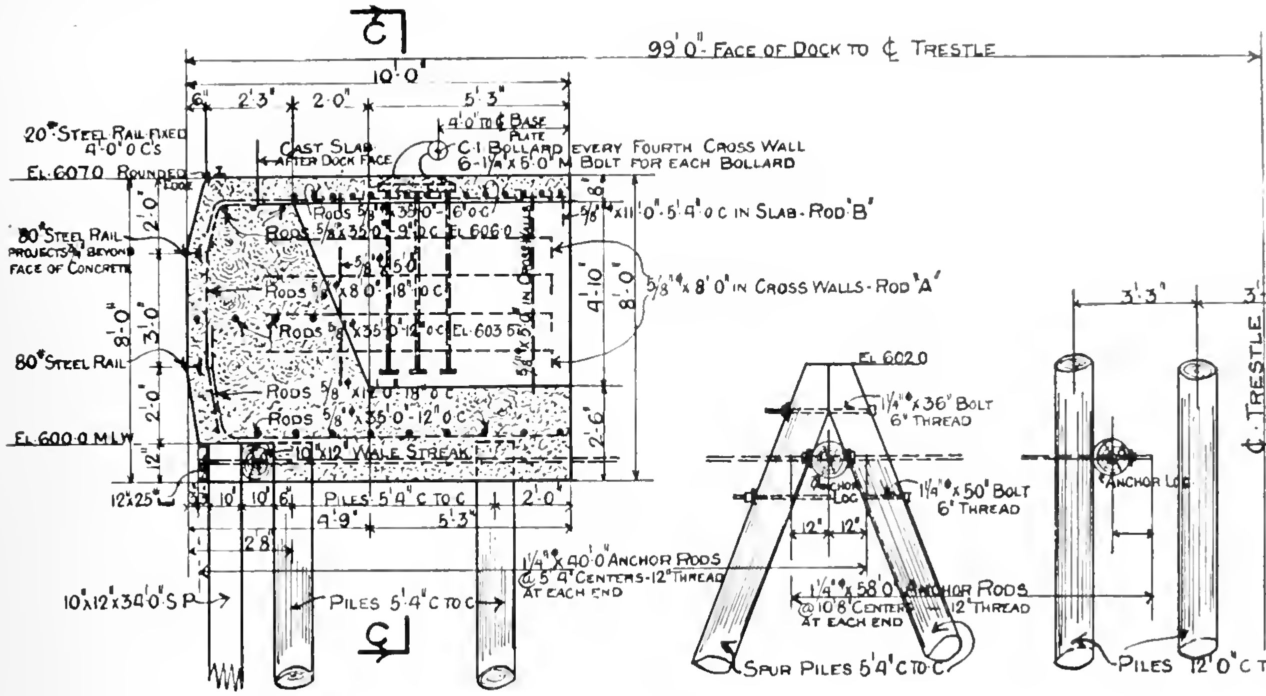


Fig. 4.—Section A A.

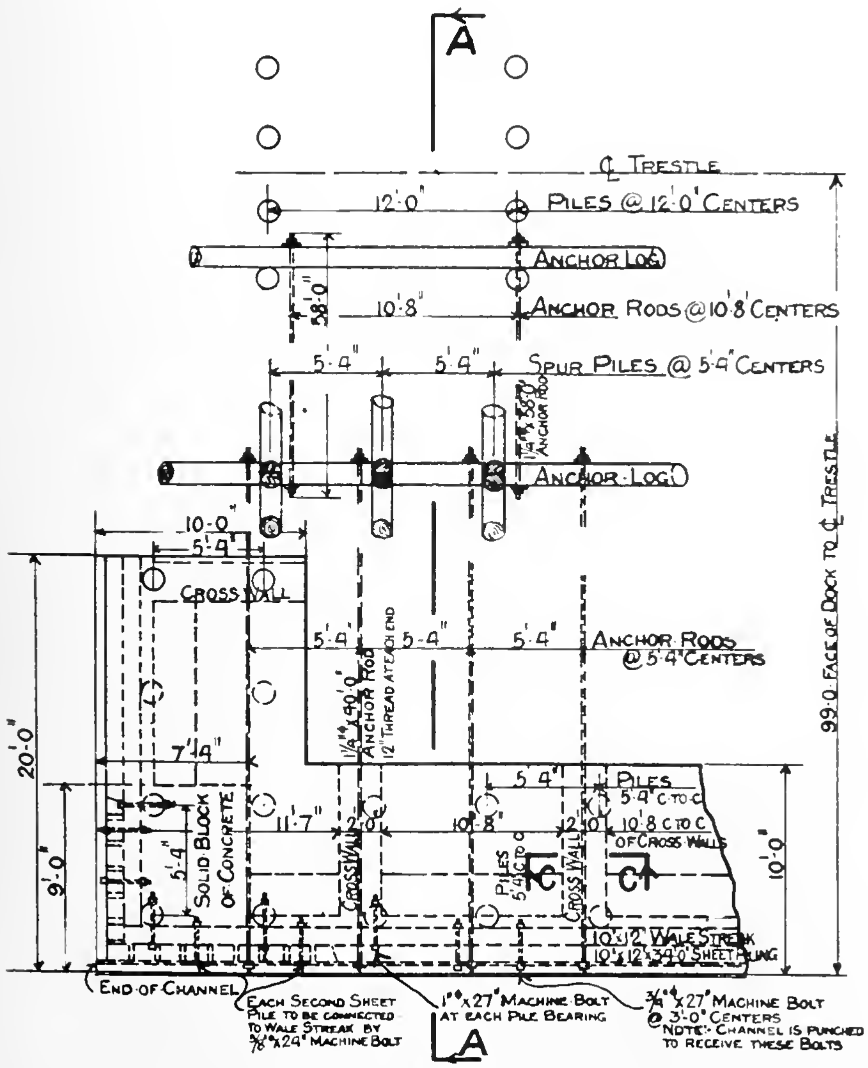

Fig. 3.—Plan at Inshore End.

Fig. 11.

The piling at the outer corner of the dock was driven, as shown in details, whilst the anchor logs, spur piles, etc., previously described, were necessary only where the 10-foot cross sectional lengths of wall were built. The 12-foot cross sectional length of wall did not call for anchor rods, spur piles, etc., the necessary anchorage being obtained by substituting 1¼-inch diameter by 16-foot anchor rods for the 1¼-inch diameter by 40-foot anchor rods used in the 10-foot section and carrying same through into the mattress of the elevator buildings, the mattress in turn being carried forward under the 12-foot section of dock wall, thus forming the bottom slab or foundation of same.

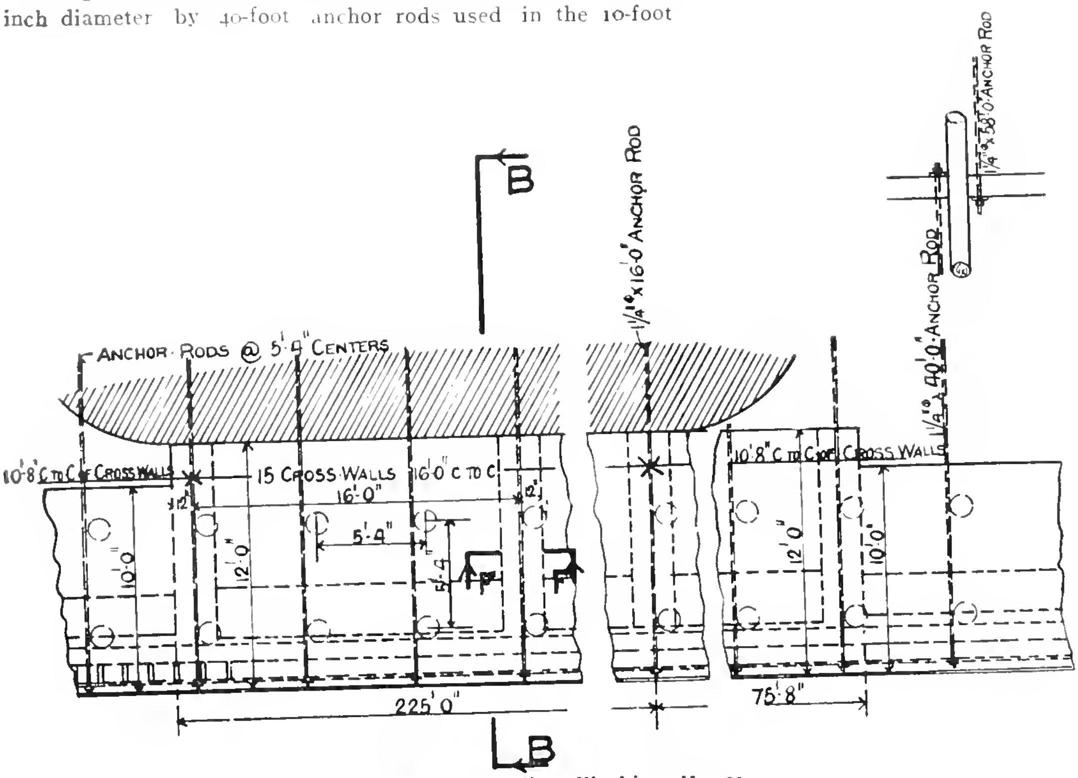

Fig. 5.—Plan Fronting Working House.

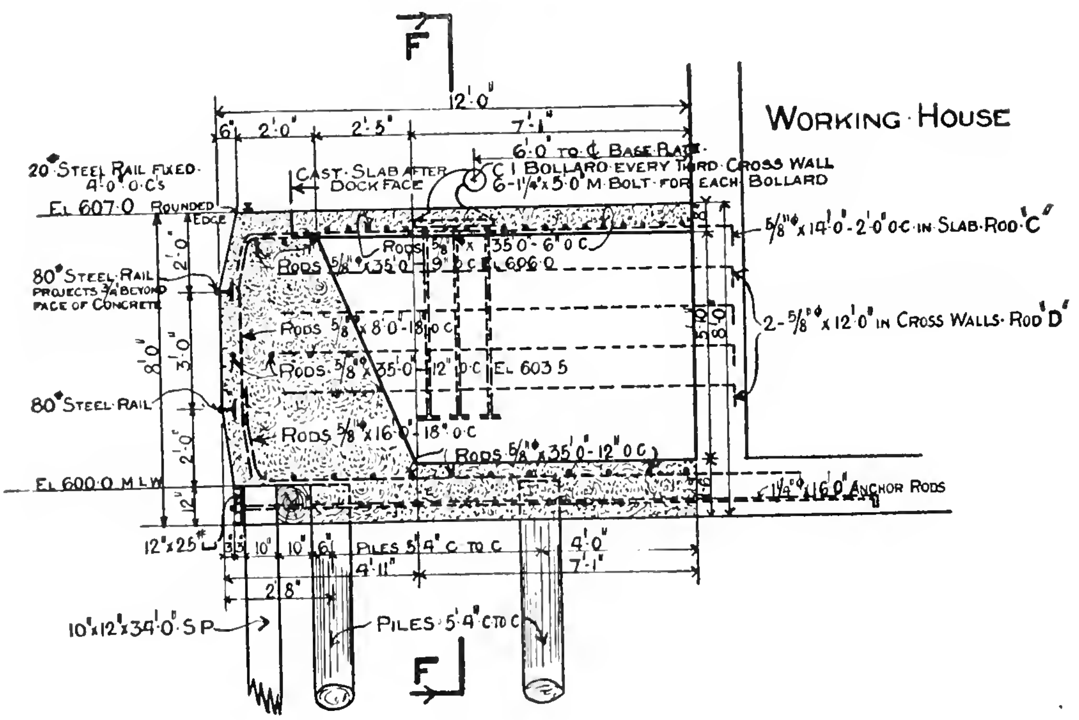

Fig. 6.—Section B B.

The sketches showing the cross sections of dock walls clearly illustrates their design and construction. The 10-foot cross section has a depth of 8 feet with an 8-inch top slab, 2-foot 6-inch bottom slab, and a connecting retaining wall of the dimensions shown. The face projects 6 inches beyond the back line of the channel iron and breaks back 6 inches at the top, the corner being rounded off. The bottom of the concrete starts at elevation 599.0, thus enclosing piles, wale streak, and anchor rods, and is finished off at the top at elevation 607.0.

Cross walls connecting the top and bottom slabs and 2 feet in thickness are cast with the dock wall, the distance from centre to centre of cross walls being 10 feet 8 inches.

The 12-foot cross section of the dock wall is similar to the 10-foot section as regards face formation and thickness of top slab. The connecting retaining wall is slightly varied, as the sketches will show, whilst the bottom slab, as previously stated, is formed by the continuation of the mattress of the elevator buildings, and is 1 foot 6 inches in depth.

The cross walls, or rather that portion of them fronting the working house, a length of 224 feet, are spaced at 16 feet centres, built on a continuation of the centre lines of working house columns. The remaining cross walls in the 12-foot section, whilst similar in construction, are built on 10-foot 8-inch centres, as in the case of the 10-foot section cross walls.

With regard to longitudinal reinforcement, the 10-foot section calls for 15⅝-inch diameter by 35-foot rods 6 inches on centres in the top slab, 3⅝-inch diameter by 35-foot rods 9 inches on centres, and 4⅝-inch diameter by 35-foot rods 12 inches on centres in the retaining wall section, and 9⅝-inch diameter by 35-foot rods 12 inches on centres in the bottom slab.

The cross sectional reinforcement consists of ⅝-inch diameter by 8-foot rods 18 inches on centres adjoining face

of dock, and ⅝-inch diameter by 12-foot rods on similar centres, running from near the face of the dock through the bottom slab.

The 10-foot section cross walls are reinforced as follows: Four cross rods ⅝-inch diameter by 8 feet, denoted rods "A," and two ⅝-inch diameter by 5-foot vertical rods. An additional cross rod ⅝-inch diameter by 11 feet denoted rod "B," and spaced 5 feet 4 inches on centres is used in the top slab reinforcement. Rods "A" and "B" are bent as shown on details, Fig 11.

Turning to the 12-foot cross sectional wall, we find the reinforcement somewhat different. The longitudinal reinforcement consists of nineteen ⅝-inch diameter by 35-foot rods, 6 inches on centres in the top slab, three ⅝-inch diameter by 35-foot rods 9 inches on centres and four ⅝-inch diameter by 35-foot rods 12 inches on centres in the retaining wall section, and eleven ⅝-inch diameter by 35-foot rods 12 inches on centres in the bottom slab.

The cross sectional reinforcement consists of ⅝-inch diameter by 8-foot rods, 18 inches on centres adjoining face of dock, and ⅝-inch diameter by 16-foot rods on similar centres, running from near face of dock through the bottom slab into the working house mattress. The top slab is further reinforced with ⅝-inch diameter by 14-foot cross rods 2 feet on centres. These rods are denoted rods "C."

The cross walls are reinforced with two lines of rods consisting each of four ⅝-inch diameter by 12-foot rods, denoted rods "D." Rods "C" and "D" are bent as detailed and listed in Fig. 11.

C.I. mooring bollards were fixed on every fourth cross wall in the 10-foot section and part of the 12-foot section of wall, and on every third cross wall in the 224-foot length of the 12-foot section adjoining the working house, whilst at the outshore corner of the dock wall a C.I. standard snubbing post was fixed.

Along the face of the dock wall two lines of 80-pound steel rails were placed, with the top of the rails projecting ¾ inch beyond the concrete face of dock. This was rendered necessary as a means of protecting the dock face from the risk of abrasion by vessels.

Near the outer edge of the dock face, at the top, was laid a guard consisting of a 20-pound steel rail held in place by ½-inch by 2-inch flat bar clips, and ¾-inch diameter anchor bolts placed at 4 feet centres. The clips serve the double purpose of holding the rail in position, and by reason of raising the base of same ½-inch above the top of dock to enable any surface water that may collect to drain off underneath the rail.

Details of the dock wall construction are given in Figs. 3, 4, 5, 6, 7, 8 and 9, whilst the details of bent rods and reinforcement list are shown on Fig. 11.

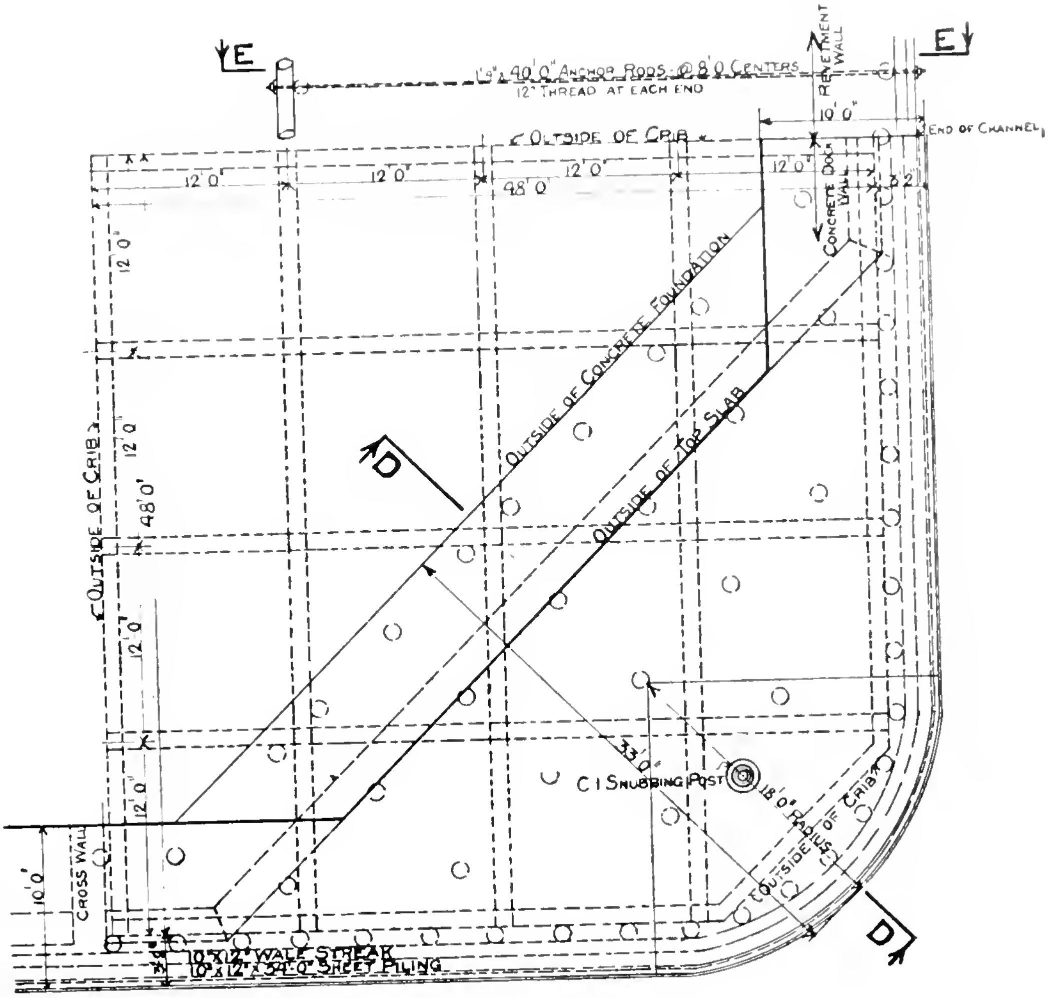

Fig. 7.—Plan at Outer Corner.

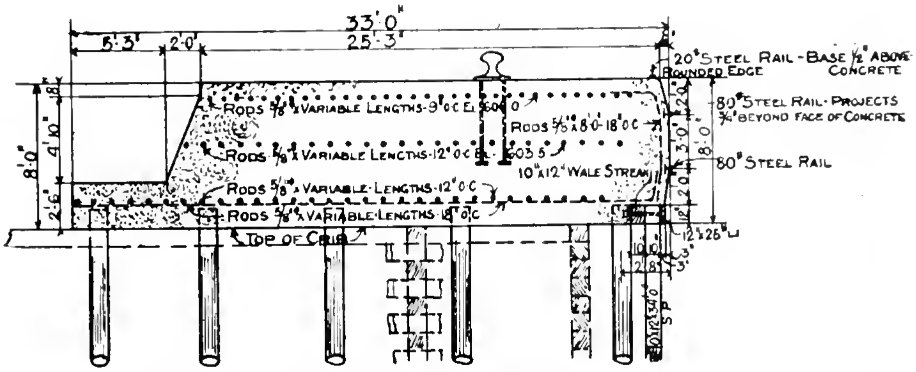

Fig. 8.—Section D D.

Revetment Walls.—Adjoining the crib end of the concrete dock wall revetment walls were built 448 feet 10 inches in length along the outshore end of the property, and 550 feet in length at right angles to last-mentioned portion and running inshore along the property line of the elevator property.

The revetment walls consist of a single row of piles, spaced 4 feet on centres to the outside of which two lines of

8-inch by 12-inch wale streaks were bolted, the wale streaks being 6 feet apart centre to centre. Outside of the wale streaks sheet piling 6 inches by 12 inches by 32 feet was driven, the piles being jetted and tapped into position and sharpened at the bottom ends in order to ensure close driving, and thus ensure perfectly sand-tight bulkhead. This sheet piling was tongued and grooved in a similar manner to the sheet piling driven in connection with the concrete dock wall, and as shown in detail in Fig. 2.

The upper wale streak was connected to each pile by means of a 1-inch diameter by 22-inch machine bolt, and the lower wale streak connected to each second pile by a similar bolt.

Each second sheet pile was connected to the upper wale

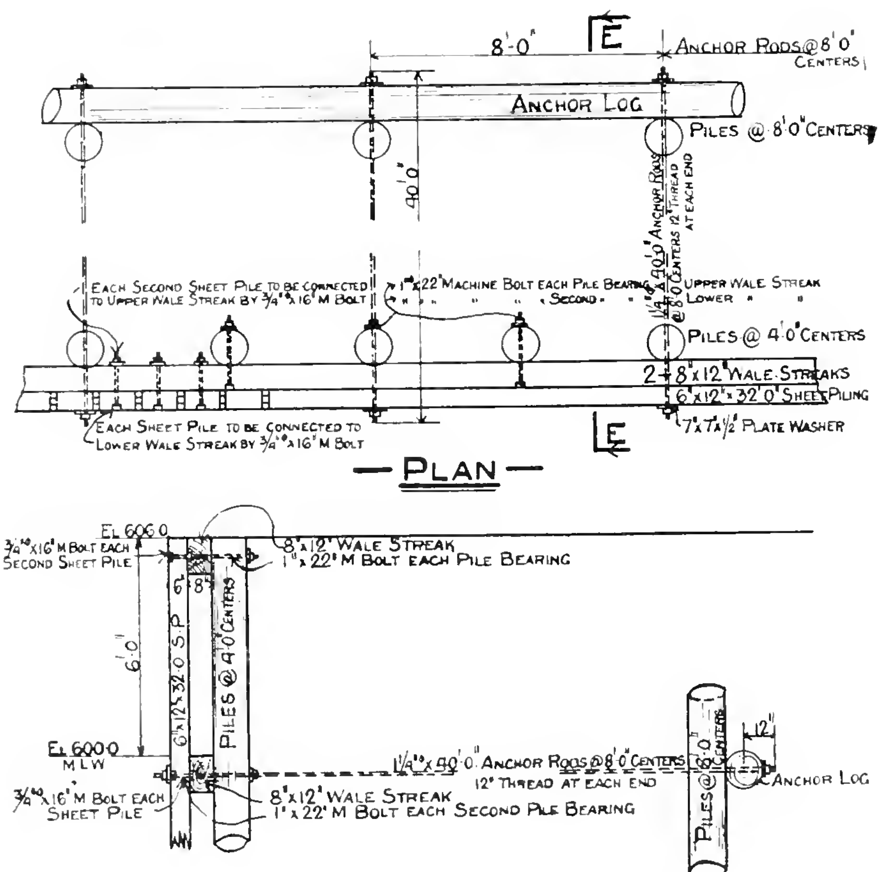

Fig. 10.—Section E E; Revetment Walls.

streak by means of a ¾-inch diameter by 16-inch machine bolt, and each sheet pile to the lower wale streak in a similar manner.

Through every second pile was passed a 1¼-inch diameter by 40-foot anchor rod, and this in turn was passed through a rear row of piles, placed 8 feet on centres, and an anchor log, held in position by the last-mentioned row of piles. The anchor rods were threaded 12 inches at each end and were fitted with wrought iron plate washers, and heavy nuts.

The pile and sheet pile cut-off and top of upper wale streak elevation was fixed at 606.0.

This elevator dock is now nearing completion, and is considered the most up-to-date dock of this particular type in the progressive port of the Twin Cities.

One of the world's newest big projects is a railway across the Sahara desert. The French government has finished its exploration. The task is difficult, but French engineers are masters. If France goes ahead plans may be ready this year.

THE HAULING CAPACITY OF LOCOMOTIVES.

At a recent meeting of the Western Canada Railway Club a paper was presented by H. D. Cameron, chief draughtsman of the mechanical department, Canadian Northern Railway, on the above subject, a portion of which we publish below.

In the earlier stages of railroading the important question of train loading was left to the discretion of the man in charge of the engine, but owing to the apparent inconsistency of the loads hauled, this method was soon changed, and the train loads for each class of engine was fixed at a certain number of cars. This method failed to discriminate between loaded and empty cars, and was followed by a system of loading by gross tonnage, i.e., it included both the weight of the car and the load.

The capacity of box cars has gradually increased in the last thirty-five years from 24,000 pounds to as high as 100,000 pounds, and the very apparent difference in hauling a train composed of empties, and one comprising loads only, disclosed the important bearing the ratio between tare and contents had on unit resistance.

This discovery led to the introduction of a system of equivalent tonnage rating.

There have been a number of different methods tried to arrive at correct equivalent tonnage. One suggestion was to arrange a special table or automatic calculator, so that the different resistances corresponding to various capacity cars, making up train, could be readily added together, and the proper tonnage obtained by balancing with calculated available tractive power of the engine. This scheme does not seem to have been generally adopted, and for present purposes the system used on the Canadian Northern Railway will be explained at length further on in the paper.

In order to follow the subject more easily we will consider it under the following sub-headings in sequence:—

1. Speed resistance.
2. Resistance due to curvature.
3. Grade resistance.
4. Tractive effort.

Speed Resistance.—Train resistance is defined as the sum of all resistances which constitute a tax on the adhesion of the locomotive. That part commonly called "speed resistance" is generally taken to mean all the different resistances that are effective on straight level track, viz.:—

1. Journal friction between journal and bearing.
2. Rolling friction between wheel and rail.
3. Atmospheric head-on resistance.
4. Atmospheric side resistance.
5. Flange friction, due to oscillation and concussion.
6. Stopping and starting resistance, or resistance due to change in velocity.

These are all variables and rather difficult to isolate and measure separately. They all act together, and, for ordinary practical purposes, it has been thought sufficient to obtain the average total resistance without determining the proportion of each individual part.

A number of the older formulæ show this resistance to be comparatively high at the start, gradually diminishing to

about twelve miles per hour, and then increasing with the speed. The later formulæ, used by the American Locomotive Company and obtained from the Pennsylvania dynomometer records, show that the resistance between five to ten miles per hour and thirty to thirty-five miles per hour is approximately constant for each different weight of car.

The following table shows the resistance of various weights of freight cars on straight level track:—

Total weight of cars, tons (2,000 lbs.)...	20	25	30	40	50	60	70	72
Resistance per ton, 5–30 miles per hour	7.84	6.62	5.78	4.65	3.94	3.44	3.06	3.00

This table shows a decided variation in resistance per ton offered by different sizes of cars. Cars weighing twenty tons require 7.84 lbs. per ton, while a seventy-two ton car needs only 3 lbs. under the same conditions. This shows quite clearly the advantage of using the largest cars possible, consistent with traffic and operating conditions, and also indicates the necessity of differentiating between large and small capacity cars.

It has been found from experiment that the resistance per ton is thirty per cent greater in empty cars than loaded ones, and this is also a factor to be considered in the tonnage of trains. From the foregoing, therefore, it is apparent that the equivalent or equated tonnage calls for some method whereby all locomotives of the same class shall be loaded so that the trains composed of loads, empties, and part loads, in different capacity cars shall offer equal resistances. The method at present in use on the Canadian Northern Railway assumes that the ideal ratio between tare and contents is two to one, and any variation from this proportion is compensated for by adding a variable percentage of the surplus tare to the sum of tare and contents. This percentage of surplus tare varies with the ruling grade for which the tonnage is determined. Thirty per cent. is used on level, twenty per cent. for grades up to 0.5 per cent., and ten per cent. for grades from 0.5 per cent. to 1.5 per cent.

Weather Resistance.—Under the heading of weather resistance is included all resistances resulting from temperature variation, wind, and snow.

Experiments by Woodbury and Beauchamp Tower show that the temperature variation has a marked effect on journal friction. At approximately one hundred degrees Fahrenheit the coefficient of friction is a minimum, and increases as the temperature is lowered. In the case of a train allowed to stand for any length of time in cold weather, considerable difficulty is experienced when starting, and it is often necessary to move small sections at a time, in order to warm up and make it possible to start the whole train. This is commonly referred to as "frozen train," but dynamometer records show that resistance in starting is not changed suddenly, as one would expect with a frozen journal, but is more or less gradual. This condition makes generous reduction on account of temperature necessary and although there have been a number of tests in this connection, there does not yet seem to be much unanimity of opinion. The following table shows reductions now in use on the Canadian Northern Railway:

Temperature Reductions—Canadian Northern Railway.

Temperature.	Reduction.
Freezing (32 degrees) or above	Nil
32 degrees above to 16 degrees above, or bad rail	5 per cent.
15 degrees to zero	10 "
Zero to 10 degrees below	15 "
11 degrees to 20 degrees below	20 "
21 degrees below to 25 degrees below	25 "
26 degrees below to 30 degrees below	30 "

In applying these temperature reductions it should be borne in mind that as soon as journals get warmed up, ordinary warm weather conditions hold so far as journal friction is concerned. In making this reduction, the proximity of the ruling grade to a terminal or point where detention is liable to occur, must be a consideration.

Wind, or the resistance offered by the atmosphere, is proportional to the square of the velocity (in miles per hour) multiplied by the cross sectional end area of the locomotive or car, multiplied by a constant equal to 0.002.

The velocity of the wind should be added or subtracted to the velocity of the train, according as it is in the opposite or same direction.

Side winds have a tendency to cause pressure of wheel flanges against the rails, thus increasing resistance considerably. Owing to the constant variation in direction of this factor, it cannot be estimated with any degree of accuracy.

Speed resistance on account of flange friction, due to oscillation and concussion, varies according to the condition of track and road-bed, and speed at which trains are run. It is not usual to consider this apart from the frictional resistance due to speed.

Momentum.—In addition to supplying power necessary to overcome the various resistances already mentioned, a locomotive has to furnish an additional amount of energy every time there is a change in velocity, either from rest, or from one velocity to another. This energy, in pounds per ton, including both the momentum of translation and the rotative energy of the wheels, axles, etc., is expressed by Henderson in the formula $P = \frac{70 V^2}{S}$ where V is the velocity in miles per hour, and S the distance in which it was acquired. Where conditions of track will admit, advantage is taken of the energy stored up in descending a grade, so that it is only necessary for the locomotive to supply the difference between the energy required to lift the train up the opposing hill, and that acquired by descent of the approach. In order to take full advantage of these conditions, the power available may be obtained by adding together the momentum energy of the train and tractive power of the locomotive.

Grade Resistance.—Grade resistance is due to the retarding effect of gravity on a train ascending an incline. It differs from the speed resistance in that it is invariable, and can be calculated exactly.

Curve Resistance.—Our knowledge of resistance due to curvature is in about the same state as that regarding some of the factors, before mentioned, in speed resistance. A good many tests have been made, but the results have not been sufficiently exhaustive, and we are still compelled to accept some approximation for our estimates. Various estimates, by different authorities, run from 0.5 lbs. to 1.72 lbs. per degree of curvature. The American Locomotive Company have taken 0.80 as a suitable mean, and this seems to be a reasonable figure to adopt. When a truck traverses a curve there are two different classes of resistance, viz.,—

1. Forces originating in truck.
2. Centrifugal and centripetal forces.

Observation has shown that on curves the tendency is for the front outside wheel to hug the rail, and the rear axles tend to lie in a radial position. Owing to the outside wheel having to travel a slightly greater distance than that on the inner rail, and on account of the wheel not being free to turn on the axle, there is a combination sliding and rolling motion of the outer wheel which further adds to the resistance. The continued relative motion between car body and truck, when traversing a curve, adds considerably to the

resistance, and efforts to reduce this to a minimum have been attempted by the adoption of roller side and centre bearings.

Experiments by Wellington show that the resistance is appreciably less with new rails, and becomes greater as the outer rail is worn to the shape of the flange. It has been found that speed influences curve resistance, and one test on a one degree curve gave one pound resistance at a speed of twelve miles per hour, and only one-half pound at twenty-two miles per hour. Experience has shown that length of wheel base considerably increases the resistance on a curve.

D—Curve in Degrees.—Centrifugal force is directly proportional to the weight multiplied by the square of the velocity. The usual practice is to elevate the outer rail a limited amount, from two to six inches, in order to counteract the tendency to lean toward the outside, and reduce the effect of the centrifugal force on the rails. From the above it is evident that a different elevation would be necessary for each different speed, and it is customary, for obvious reasons, to make this elevation suitable for passenger trains running at high speed. It is consequently too high for slow freight trains, and where curves happen to come on a ruling grade the tendency is to cause a slight increase in the resistance of the freight train. This is overcome by compensating the grade 0.04 per cent. for each degree in curvature.

Tractive Effort.—Having considered the various factors which go to make up train resistance, we now direct attention to the power developed by the locomotive, and particularly that part due to the friction between the rim of drivers and rail, and the power available for hauling train at rear of tender.

The available tractive power at slow speed is derived by equating the work done in the cylinders, to the work performed at the circumference of the drivers in one revolution. By the solution of the equation we obtain tractive effort—

$$\frac{\text{Mean effective pressure} \times (\text{piston diameter}) \times \text{stroke}}{\text{Diameter of driving wheel}}$$

The mean effective pressure is usually taken as eighty-five per cent. of the boiler pressure. In order to obtain greater accuracy it is customary to consider the resistances of locomotive and tender separate from the cars, and these may be grouped under the following headings:—

1. Internal friction of locomotive, found by experiment to be 22.2 lbs. per ton weight on the drivers.

2. Weight on drivers multiplied by grade resistance.

3. Resistance of engine and trailing trucks, and tenders taken same as car resistance in train.

4. Head-air resistance equal to $0.002\ V^2 \times A$ where V is miles per hour, and A the front area of engine (usually taken 120 square feet).

5. Curve resistance .8 lbs. per ton per degree.

6. Reduction necessary account of increase in speed, shown in attached table.

Table of Speed Factors.

Piston speed, feet per minute—

250. 275. 300. 325. 350. 375. 400. 425. 450. 475. 500. 525. 550.

Speed factor—

1.00 .976 .954 .932 .908 .886 .863 .840 .817 .795 .772 .750 .727

Piston speed, feet per minute—

575. 600. 625. 650. 675. 700. 725. 750. 775. 800. 850. 900.

Speed factor—

.704 .680 .660 .636 .614 .590 .570 .550 .530 .517 .487 .460

Piston speed, feet per minute—

950. 1,000. 1,100. 1,200. 1,300. 1,400. 1,500. 1,600.

Speed factor—

.435 .412 .372 .337 .307 .283 .261 .241

The sum of the above mentioned resistance must be deducted from the tractive effort, in order to obtain the net power available for hauling of trains. In order to illustrate this, let us take the example of a consolidation engine with the following dimensions:—

Cylinder, 24 x 32.
Wheel, 67 inches.
Boiler pressure, 180 lbs.
Weight on drivers, 104 tons.
Weight on engine truck, 12 tons.
Tender, loaded, 75 tons.

The problem is to find the net available tractive power and proper tonnage for this engine, in order that twenty miles per hour may be maintained on a 0.5 per cent. grade.

Tractive effort (MEP 85 per cent. of boiler pressure)—49,475 lbs.

Speed, twenty miles per hour, therefore piston speed of this engine is 629 feet per minute, and speed factor from above table is 65 per cent.

Available tractive effort at this speed........		32,158.75 lbs.
Resistance due to grade, account of weight on drivers 104 × 10	1,040	
Resistance due to grade and speed on tender (2-3 load) and engine truck —72 × 13.94	1,003	
Resistance due to head air—120 × 0.002 × 20 × 20	96	
Resistance due to internal friction—104 × 22.2	2308.8	4,447.80 lbs.
		27.711 lbs.

$$\text{Tonnage, 50-ton capacity cars } \frac{27711}{13.94} = 1{,}987 \text{ tons.}$$

From the foregoing it is evident that the work done by an engine is limited by either the boiler capacity or the power adhesion. Engines are compared with respect to their adhesion by comparing the factors of adhesion, i.e., the ratio between weight on drivers, and tractive effort, which usually runs somewhere between 1-4 and 1-5.

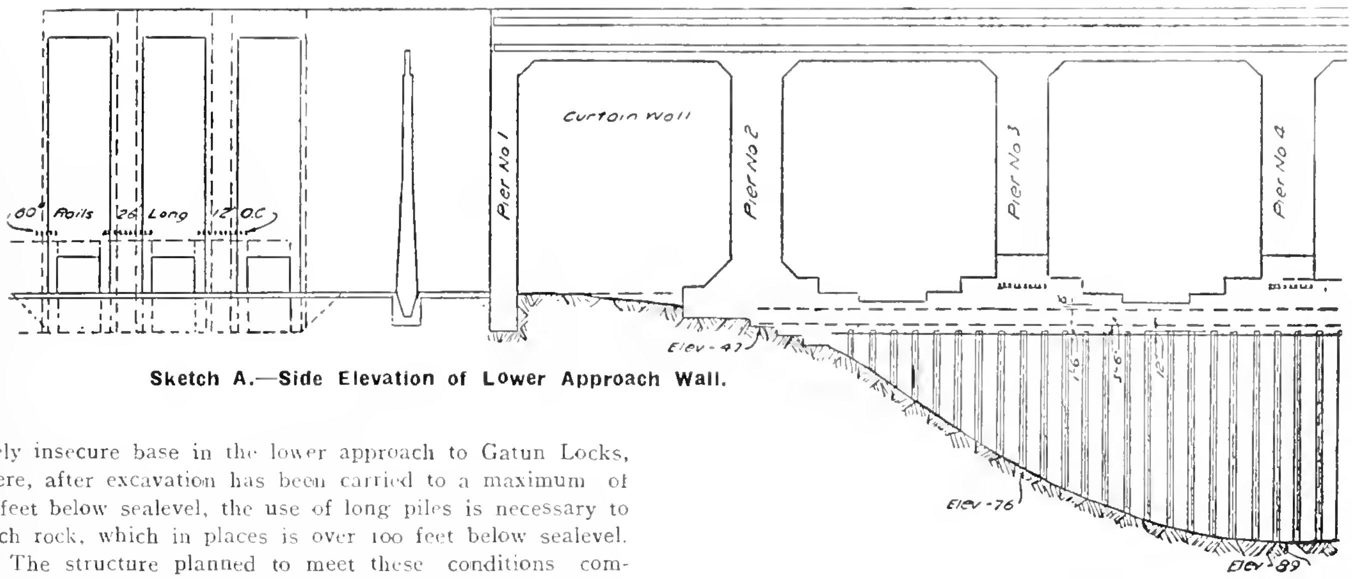
The boilers of most engines are unable to supply sufficient steam to develop full tractive effort at speeds higher than eight or ten miles per hour, and after this critica speed has been reached the boiler becomes the limiting factor to be considered in connection with load and speed. It will, therefore, be readily seen that on long level sections the boiler capacity becomes the principal factor in fixing train loads.

RAIL FAILURE TESTS.

Ninety per cent. of rail failures, as stated by Mr. M. H. Wickhorst, engineer of tests for the rail committee of the American Railway Engineering Association at the recent convention of the association, are failures either of the head or web, which constitute 50 per cent. of them; or of the base, which constitute 40 per cent. The cause of the former he ascribes to unsound ingots, and the remedy he says is a more uniform chemical structure in the ingot. For the base failures he blames laminations in the base, and suggests as a cure better mechanical rolling.

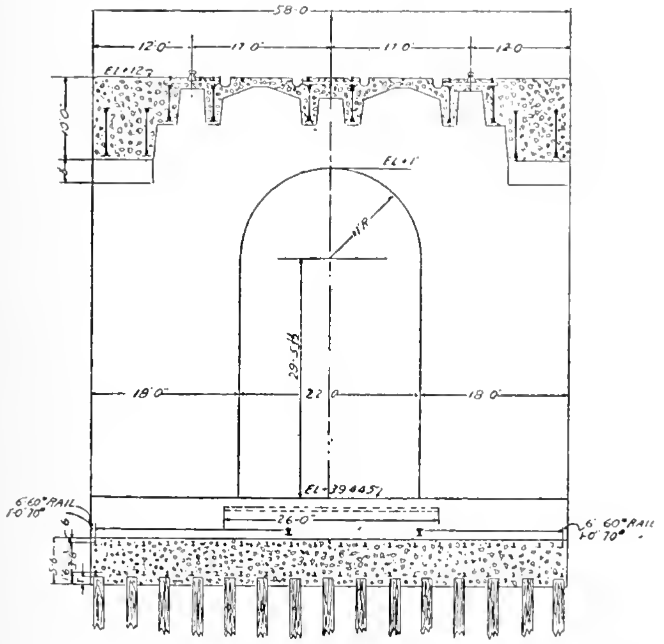
LOWER APPROACH WALL AT GATUN, PANAMA.

The lower approach wall of Gatun Locks, at the Atlantic end, differs from the five other approach walls in the Canal lock construction. The cellular form of reinforced concrete used for the upper approach walls at Gatun, Pedro Miguel, and Miraflores Locks could not be used in sea water, because of its possible effect on the steel reinforcement. The heavy U-section, double gravity-wall used for the lower centre guide walls at Pedro Miguel and Miraflores, and founded directly on rock, would be too heavy for the relatively insecure base in the lower approach to Gatun Locks, where, after excavation has been carried to a maximum of 50 feet below sealevel, the use of long piles is necessary to reach rock, which in places is over 100 feet below sealevel.



Sketch A.—Side Elevation of Lower Approach Wall.

The structure planned to meet these conditions comprises a series of piers, connected by flat spans above, to form a causeway of successive flat-span bridges. The original plans contemplated that the piers should rest on broad bases surmounting the piles, but would not be connected at bottom. Excavation revealed, however, softness in the earth overlying the rock which was not shown by the borings made at the time of determining the lock site. It became necessary to bind the piers together and protect them against transverse sliding. Accordingly, the piles, which are driven on four-foot centres, longitudinally and transversely, and on 3-foot centres for the outermost two hundred feet, are surmounted by a continuous base of concrete, which extends a foot below the top of the piles.



Sketch B.—Sectional View (Twenty, 50 ft. Apart, Support the Causeway).

This base is 58 feet wide. The bottom is level, but the top is a series of inverted stepped arches, described on a radius of 42 feet. The haunches between the successive inverted arches form the bases of the piers of the flat-span bridge. At the lowest step of the inverted arches, the thickness of the base is five feet seven inches; at the springing line it is 10 feet seven inches. Several of the arches were constructed with the soffit on a curve, but for the sake of speed in construction, with consequent economy, as well as to afford better bracing for the forms in the erection of the piers, the stepped arch was adopted. The lower part of each riser is on the circumference of a regular segment, with 42-foot radius, so the strength of the arch is not diminished. Reinforcement in the base consists of twenty continuous longitudinal rows of 70-pound rail, resting on the tops of piles; and duplicate rows of similar rail four feet six inches higher up. The side elevation of the base, and of a portion of the completed wall, is shown in the accompanying sketch marked A.

A transverse section of the wall is shown in Sketch B. Each pier, as shown, consists essentially of two piers, connected by a semi-circular arch. The horizontal normal section of each component is 18 by 10 feet; the inner sides are vertical for a height of 22 feet five and 11-32 inches, this point above the base being the springing line of the arch, which has a radius of 11 feet. On the outer faces the piers are vertical from base at elevation—39.37 feet, to the top, which is 12 feet above sealevel. The shaded sections shown in Sketch B are not parts of the pier proper, but of the spans connecting the piers in the causeway. The piers, 20 in number, are set 50 feet apart, centre to centre. The spans connecting them are carried by four 6-foot, and six 4-foot 6-inch plate girders, encased in concrete. The tops of the spans will be left uneven, in preparation for the grouting necessary to the laying of track for the towing locomotives.

The six spans of wall nearest the locks are closed by 2-foot curtain walls. This is to prevent water from surging from one approach channel to the other, between the piers, when a lock is discharging. Beyond the sixth pier the spans will be open, and the bottom of the spans will be two feet

above the water. The wall will extend 1,016 feet from the line of the fender chains, and will contain approximately 45,000 cubic yards of concrete.

BUILDING MATERIALS IN WESTERN CANADA.

With the exception of British Columbia there is very little building stone produced in Western Canada. This is due to two causes. First, the rocks which underlie the developed portions of the Prairie Provinces are of comparatively recent age and are consequently soft in character and weather rapidly; second, there are very few rock exposures in the settled portions of these provinces except in the Rocky Mountains and the foot hills.

In British Columbia there are large potential resources of building stone. They have, however, been developed only in certain localities on the Pacific Coast and have been confined to Cretaceous sandstone and certain volcanic rocks, situated on Vancouver Island and adjacent islands. Varieties of marble are also quarried on Texada Island.

While the prairie Provinces have not been proved to contain building stone in great quantity they possess large deposits of lime-rock shales and clay suitable for the manufacture of cement; also large deposits of clay and shale suitable for the manufacture of brick of various kinds, tiles, sewer pipe, etc.

The region bordered on the east by the Great Plains, and on the west by the Coast Range, does not, so far as known, contain extensive clay resources. Shales also are rare because, in most instances, the deposits of argillaceous material have been altered to slaty rock or schists.

Exploration in the Pacific Coast region has, thus far, disclosed only a limited extent of clay resources, but important shale deposits are found at Sumas Mountain, southeast of Vancouver. Surface clays are more extensive than the shale deposits and a number of these clays are found in the vicinity of Vancouver, Victoria and on several of the islands in the Strait of Georgia.

The cement plants in operation in Western Canada are situated at Babcock, Manitoba; Winnipeg, Man., (under construction); Calgary, Alta.; Exshaw, Alta.; Blairmore, Alta. (one operating and one under construction); West of Edmonton, Alta. (one under construction); Todd Inlet, B.C. (one operating and one under construction).

In the above list there are four new plants described as under construction, but all expect to be in operation in the spring of 1913. The Rocky Mountains undoubtedly contain enormous deposits of raw material similar to that used at Blairmore and Exshaw which will be developed as the demand increases.

UNEXPECTED RAILWAY TESTS.

Fifty-one thousand surprise tests were conducted by the Pennsylvania Railroad last year to test the alertness of its men in heeding signals. In these there were 510 failures on the part of the men to obey the signals, and the railroad company, arguing that each of these failures contained the possibility of an accident, protests vigorously against a bill introduced into the New Jersey Legislature requiring the railroad to give previous notice in writing to the engineman where tests of apparatus are to be made.

RECOMMENDED PRACTICE IN RAILWAY LOCATION.

At the recent annual meeting of the American Railway Engineering Association, the following notes for railway location were presented by a committee on "The Economics of Railway Location":—

Value of Maintaining Original Profile.—Railroad profiles change in the course of years. It is a well-known fact that fills settle, causing deep sags in the grade line. The raising of tracks through cuts is cheaper than ditching, but is responsible for summits in the cuts.

In the early days it was not as thoroughly realized as it is at the present time that maintenance of way is chiefly a matter of drainage. Shortage of money was also responsible in a large measure, for narrow cuts which were difficult of drainage. In the effort to get away from this condition, and to secure a ditch, tracks were raised, thereby causing steeper grades than were originally projected. Every cut being followed by a fill, the sequence of raised cuts and depressed fills has caused a wide variation from the original ruling grade.

On some lines, where the profile has been checked, it has been found that stretches of 0.3 per cent. grade have become 1 per cent. If places of this character occur near a point of heavy resistance, an immediate effect on the tonnage of a train is the result. When an engine is working with its bar well forward, with the fireman tired out, the fire dirty, and the steam pressure dropping, such places will cause the stalling of a train, and in a short time the frequent delays will result in decreased tonnage rating.

Raising tracks is not as economical as the section foreman and supervisor would lead us to believe. While better drainage is undoubtedly secured, it is generally better practice to clean the ballast, and widen cuts to secure a ditch, and to raise track only when it becomes necessary to put roadbed to a proper line and surface. On such occasions, grade stakes should be used to establish the grades.

On many railroads an effort has been made to place permanent monuments, so that the track could be kept at a constant elevation. The difficulty of maintaining monuments along a roadbed is well known. They are not only likely to be a menace to the lives of the trainmen, but they are constantly settling, and being knocked by sectionmen, and occasionally by derailments. However, the importance of placing permanent monuments cannot be over-estimated.

Compensating Old Roadbeds.—In the early days of railroading, compensating for curvature was practically unknown. For many years it was probably unnecessary. Compensation for curvature is not vital to small trains running at speed. The resistance due to curvature is principally felt by heavy tonnage trains on ruling grades where the engine is rated at a high percentage of its cylinder tractive power. Various experiments have been made to determine how much reduction in grade would compensate for the added resistance of curvature. It has generally been the practice to compensate this at a stated amount, and, while this method is not as accurate as could be desired, it is very much better than no compensation at all. From considerable observation of the influence of curvature, together with the examination of numerous tests of its effect, it is felt that some rules can be laid down which will improve the present practice. The rules follow:

Rules for Grade Compensation.—1. Compensation .03 per degree:

(a) When the length of curve is less than half the length of the longest train.

(b) When a curve occurs within the first 20 ft. of rise of a grade.

(c) When curvature is in no sense limiting.

2. Compensate .035 per degree.

(a) When curves are between ½ and ¾ as long as the longest train.

(b) When the curve occurs between 20 ft. and 40 ft. of rise from the bottom of the grade.

3. Compensate .04 per degree.

(a) Where the curve is habitually operated at low speed.

(b) Where the length of the curve is longer than ¾ of the length of the longest train.

(c) Where super-elevation is excessive for freight trains.

(d) At all places where curvature is likely to be limiting.

4. Compensate .05 per degree wherever the loss of elevation can be spared.

An illustration will show what can be accomplished by compensation of curvature on old roadbeds:

Take a 0.5 per cent. grade five miles long, with an average curvature of 60 deg. per mile, without compensation. If the maximum curve is 6 deg. and the curve equal in length to the longest train, the curvature will have the same effect in limiting tonnage as a grade of 0.24 per cent. This, added to the 0.5 per cent. grade, would make a ruling grade of 0.74 per cent. The effect of the curvature on the five miles of grade would be 300 deg., which, at an average of 0.035 per degree, would amount to 10½ ft. If this 10½ ft. is added to the 132 ft. of rise in the five miles of grade, it will be equivalent to 142½ ft., or 28½ ft. to the mile, which is equal to a 0.54 per cent. grade. If this 0.54 per cent. compensated grade is laid so as to be superimposed immediately above the present roadbed, it will be found that by re-ballasting the track to permanent stakes on a 0.54 per cent. grade, a new ruling grade can be established, which will be 0.2 per cent. below the 0.74 per cent. equivalent to the 0.5 per cent. uncompensated grade. On a grade of this length, it will be possible to haul nearly 25 per cent. greater tonnage per train, thereby securing a very large economy in operation for a small expenditure of money.

Compensation of Low Grades.—The effect of curvature on low grades is generally greater than on heavy grades, provided the length of train is what would be justified by the low grade. In speaking of low grades, levels, 0.1 per cent., 0.2 per cent. and 0.3 per cent. grades are referred to.

On double track railroads, particular attention should be paid to curves, whether uphill, downhill, or level, at places where steam is being taken by the engine in moving in either direction. On virtual level grades each track should have its tangents slightly raised and its curves slightly sloping downhill, so that the pull by the engine may be uniform, and the resistance of the line constant. The value of keeping the line resistance constant becomes more important as the length of the train increases. One of the prime objections to hauling a long train is the danger of parting, and in this danger curvature plays an important part. If the line is crooked, having many short curves, it is usual for the slack of the train to be constantly taken up and let out. If the engine runs out on a bit of straight track, when the rear of the train is bunched on the curves, it will accelerate faster than the other end of the train. Unless the engineer is watching, and using the brakes slightly, he may pull out a drawbar. If, on the other hand, the front end of the train is on a curve, and the rear end on straight track, the tendency is for the rear end to run in on the front end, and break a knuckle. It should not be supposed that it is impossible to have different classes of compensation on each track of a double track railroad.

Super-Elevation.—From a scientific standpoint (not always from a financial view), it is evident that a six-track railroad is the most desirable for a road that handles a three-speed service. This will give a passenger track, a fast freight track, and a slow freight track in each direction. Without attempting to discuss at this time what will be gained by the operation of a six-track railroad, it should be said that as many tracks as possible are justified if a standpoint of super-elevation alone is considered. Of course, it becomes necessary for a train to stop occasionally on a curve, and for that particular case the super-elevation is always wrong.

Inasmuch as no super-elevation at all is necessary at very low speeds, it may be eliminated entirely on tracks that are used exclusively for standing cars, and very low super-elevation, if any, should be used in yard tracks.

On a single-track railroad carrying more than one class of traffic, there are two ways to treat super-elevation:

(1) Make the freight tonnage rating as great as possible, and in accordance with the ruling grade. In this case, it will be necessary to elevate the curves for freight speed, and run the passenger trains slowly over the ruling grades.

(2) Use a higher super-elevation for passenger speeds, and decrease the tonnage rating to make up for the increased resistance caused by the wheels of the freight trains binding against the lower rail.

Single-track railroads which are crooked can rarely haul as high a percentage of rating as double-track railroads, on account of the super-elevation being wrong. It is very easy to see that every down-grade becomes an up-grade for movements in the opposite direction on a single-track road. Inasmuch as the movement downhill is likely to be faster than the it is uphill, the super-elevation must be made for the downhill movement or introduce speed limits on downhill trains.

Resistance, Train, Total, Including Track.—On single lines that are exclusively for freight, super-elevation on ruling grades should be made for not over 15 miles per hour. It is less expensive to slow down the descending movement than to reduce tonnage rating on account of excessive super-elevation.

This is especially true on curves of large central angle. As an example, a curve of 18 deg. is cited. Two engines (one helping) hauling 3,500 tons of coal ordinarily stalled on an 8 deg. 30 ft. curve with 185 deg. central angle with 5½-in. elevation. The elevation was reduced to 3 ins. and no difficulty was had. This curve was compensated .04 per degree and was an 0.85 per cent. grade.

On many mountain roads a long train may be on seven or eight curves at once, and when such is the case, observation of minor points is of great value when tonnage is the main issue.

Spirals.—Without discussing the theory of the spiral as affecting railway grades, it should be said that the object of the spiral is twofold:

(1) To afford a run-off and a run-on from a level cross-section to a super-elevated cross-section.

(2) To ease the horizontal passage from a straight line to a curve.

It is evident that in passing from a level position to a super-elevated position, when the inner rail of the curve is laid at grade, the centre of gravity of the mass of the train

must be raised through a distance equal to one-half the super-elevation. This is generally a minor rise, but in order to haul uniform tonnage this minor point should be carefully observed, especially where limiting conditions are found, such as places near the end of a long-continued effort. It has been proposed in the past that the inner rail be depressed a distance equal to one-half of the super-elevation, and the outer rail be raised the same amount. While this has been objected to by some railroad men, it can certainly be done and so maintained, and from a tonnage haulage standpoint it is desirable. It is submitted that the railway of the future, which is scientifically operated, will find conditions such as these limiting their tonnage unless care is taken. While it might be said that refinements in the track are unimportant, it should be borne in mind that, in order to realize the full value of improvements, these matters must be taken into consideration. A combination of correct conditions results in the most effective operation.

Reverse Curves.—Curves that reverse without any tangent between them mean operating expense. Not only must the super-elevation change abruptly, but the trucks must change their position in the same manner. It is considered good practice to leave room between the points of spiral for four freight cars to straighten up after they change direction. On most new construction, provision is made for at least 1,000 ft. between curves, and this practice is recommended unless great expense is involved.

Effects of Tunnels.—Many railroads are suffering today on account of the fact that during the early days of construction it was not thoroughly realized that a tunnel might be a limiting feature. The following are the causes of the limiting effect of tunnels: (1) A tunnel is dark, making the crew less confident. (2) A derailment in a tunnel is almost sure to result in serious damage and loss. (3) The heat in long tunnels, especially if of small section, is intense. (4) The track conditions, such as line and surface, are never as good as on the outside. (5) The rail is generally damp, causing either the excessive use of sand, or the slipping of drivers. (6) Drainage in tunnels is usually bad, and difficult to improve. (7) There are usually speed restrictions in tunnels. (8) It was formerly the practice to carry maximum grades through tunnels in order to shorten them. This serious defect in many cases makes tunnels the ruling points. (9) In tunnels of small section the use of helper engines is undesirable on account of the heat. (10) The smoke and gas add to discomfort of operation. (11) The impracticability of firing in long tunnels causes a drop in steam pressure.

There have been many plans devised for tunnel ventilation. Most of them are successful under some circumstances, but none is successful under all conditions. Long tunnels are generally built by means of shafts, and these shafts are sometimes left open to aid the ventilation. If the heat in the tunnel is greater than that outside, shafts will help when the atmosphere is low in humidity. When the humidity is high, shafts make but little difference in tunnel conditions. This is unfortunate, as tunnels at such times are very foul. Disc fans used in the shaft will operate satisfactorily sometimes, but their efficiency seems to vary about the same as the open shaft. Pure air blown down shafts is successful at times, but if the shaft is near the centre, it generally happens that only one end of the tunnel is cleared out, the air remaining stationary at the other.

The Churchill system of ventilation, by which pure air is blown through the tunnel from one end through nozzles fitted at the sides of the tunnel, is successful, if the enginemen operate the locomotive so that the smoke is blown ahead of the engine. If two engines are used ahead on a train, and it is necessary to work the second engine, the position of the front engineer is unbearable. If one engine is used in the rear and one in front, and the smoke and gas from the second engine reaches the first one, the front engine crew are in the same position as in the case of the double-header, but if the train is skilfully handled, the smoke and gas of the rear engine will not reach the head engine. In tunnels where the grade inside is considerably less than the ruling grade, it is sometimes found possible to shut off one engine entirely, and in that case there is no difficulty, provided that the train does not move faster than the air current.

The natural tendency is to drive the engine as hard as possible through the tunnel on a heavy grade in order to get through quickly. The speed of the air currents in the Churchill system of ventilation in a tunnel a mile long usually averages about 8½ miles an hour over the whole distance. If the tunnel is being worked to anywhere near its capacity, the additional time in the tunnel may seriously limit the number of trains that may be put through. It has been found, however, that if the tunnel is cleaned out by the ventilating apparatus before the passage of each train, there is little difficulty in getting through. As a rule, the engine crews prefer this method.

Double-track tunnels are of sufficient section so that there is little discomfort in a tunnel a mile long, even if the locomotive is fired all the way through. The practice in Europe has always been much better than that in the United States in that even with single-track tunnels their section has been large enough so that they are less uncomfortable than those in this country. Tunnel ventilation in Europe is largely restricted to the dilution of locomotive gas with plenty of fresh air rather than driving the smoke and gas ahead of the engine.

In the construction of new tunnels, an effort should always be made to reduce the grade in the tunnel considerably below the ruling grade, so that there may be no need of touching the fire during the passage through the tunnel. Ample section to secure good conditions is essential. In this connection it should be noted that the effect of long single-track tunnels of narrow section on the ruling grade is to reduce the tonnage rating in the tunnel by 10 per cent. at least.

THREE NEW ALLOYS.

In their last official report as chemists to the American Institute of Metals, Arthur D. Little, Inc., of Boston, mention three new alloys among the various items of recent progress in the metal industry.

A French patent has recently been issued covering the production of two types of alloys from copper, zinc and silicon which are claimed to possess great tenacity, resistance to acids and alkalis and to be capable of rolling into finished shapes.

Another new alloy has been patented by the Ajax Metal Company, composed of iron, nickel and copper, which is claimed to be non-corrosive, malleable, of great tensile strength and capable of being rolled, drawn or cast.

A new type of pyrophoric alloy has been patented in Germany which consists of the addition of 5 per cent. metallic cerium to an alloy of manganese and antimony. The inventor claims excellent pyrophoric properties from this alloy which is essentially different from the other alloys of this type in which cerium is the main source of the pyrophoric characteristics.

COSTS OF CONCRETE PAVEMENTS.

In a paper before the American Society of Engineers and Contractors, and reprinted in the Journal of the Society, pp. 435 to 450, C. M. Boynton, inspecting engineer, Universal Portland Cement Company, writes on "Concrete Pavement; Methods and Cost of Construction." The following data is abstracted from same:—

An analysis of the material costs of one-course and two-course work will show that the difference is so very slight as to be doubtful of estimation. However close an approximation an estimate may be, it cannot be exact, and, therefore, it will readily be seen in the following formulas that the main consideration in choice of type of pavement must necessarily be dependent upon the materials available; and the type chosen will be that to which thy are best adapted. This formula is based on Taylor & Thompson's Table of Proportion.

Considering: C equal cost of cement per barrel,
G equal cost of gravel per cubic yard,
S equal cost of sand per cubic yard.

Then, for one-course work of 1:2:3 mix, 7 ins. thick, the material cost per square yard of pavement is .325C plus .0975S plus .146G; while for two-course work, 7 ins. thick, composed of 1:2½:5 base, and a 1:1½ top mortar, the material cost per square yard of pavement is .342C plus .1045S plus .133G.

These two formulas show the tendency to equalize the cost by small compensating differences in the several quantities and are given here to illustrate this point.

With good equipment and an average gang the actual cost of mixing and placing should not exceed 7 cents. per square yard for 7 ins. of concrete. To this should be added a cost of 3 cents per square yard for finishing and labor necessary for handling the forms, making a total for one-course work of 10 cents for mixing and placing. As has been stated, there is a slight difference in the cost of placing single and two-course work, with the advantage in favor of the former.

Placing expansion joints is such a simple operation that 1 cent per square yard should cover the cost. To this must be added the cost of metal joint and tarred felt delivered on the job, or the cost of filling the joint with a plastic filler.

On city streets the water supply is not a problem; but on country highways, where it is necessary either to haul or to pipe water a considerable distance, it is advisable to make a careful survey of the situation. In estimating the cost of water the amount required for keeping the pavement damp for a period of five days must not be neglected, and as this is an indefinite quantity dependent upon weather conditions, only an approximate cost can be suggested. On the Wayne County, Michigan, work the water for each road is costing $3.50 per day (the wage for a man looking after the pumping), plus oil and gasoline required in operating the engine and pump. Water for the Mukwanago Road in Milwaukee costs 1¼ cents per cubic yard of pavement. In this case the water is purchased from the city of Milwaukee or its suburbs. In both cases the contractor's and builder's equipment must include the necessary engines, pumps, piping, etc.

The cost of hauling water for use in constructing country highways of concrete is often an item worthy of careful consideration. The method of supplying water by piping is considered by the majority of contractors as most economical. Where water is available under sufficient pressure the pipe line can be attached directly to the city main, thus eliminating engine and pump, but where water is taken from a well, creek or river in vicinity of work, an engine and pump will be required. The cost of gasoline engines varies with rated horse power from approximately $105 for a 2-h.p. engine to $320 for a 9 h.p. The cost of pumps would vary according to the capacity pressure required and the conditions under which work would be performed.

On one job in the vicinity of Milwaukee, 7,200 lin. ft. of 2-in. pipe at $6.80 per 100 ft. cost $489.60, and the laying, $20 per mile, amounting to $27.20, makes the total cost $516.80, or $0.072 per foot. On the other job 11,200 ft. of 2-in. pipe cost $1,008 laid, or $.09 per foot. For supplying water, the city of Milwaukee received $.005 per cubic yard of concrete mixed and $.005 for each square yard of pavement, making a cost of $.00583 per square yard of finished pavement.

Where the construction is small, the installation of efficient pumping equipment may not be justified, in which case hauling in tank wagons can be resorted to. One team hauling tanks having upwards of 350 gals capacity will supply a mixer of ⅓ cu. yd. with sufficient water for a day's run, provided the haul is 1½ miles or less. On one job of 4,800 sq. yds. in Wisconsin the water cost $75 for the entire work, plus the cost of hauling and pumping, which was $7 a day for 10 days. Another contract was $10 for water and $4 a day for hauling. This work covered 3,500 sq. yds., but the haul was short and one team working half a day could keep the mixer supplied.

In discussing the cost of concrete pavements, a few examples of actual construction will help to make clear the division of expense. The first pavement was laid recently in a small town in the central part of Illinois, totaling 5,000 sq. yds. The total cost of the work was $3,964.02, excluding cost of equipment, which consisted of a ½ yd. Koehring mixer of the latest type and a 4½-h.p. gasoline engine, and also excluding the cost of the water for mixing and sprinkling. The pavement was 45 ft. wide and uniformly 6 ins. thick. The cost of the work was divided as follows:—

Superintendence	$ 140.00
1,457 bbls. cement	1,547.15
Sand, stone and gravel	1,284.97
Labor	560.07
Lumber and forms	35.00
Bitumen and creosoted blocks for joints	48.67
Coal and oil for mixer and engine	30.75
Excavation	307.41

A summation of these figures gives the cost of this road as $4.76 per cubic yard or $0.79 per square yard.

During the summer of 1912 Milwaukee County, Wisconsin, constructed several concrete highways to the south and southwest of Milwaukee. Data on a two days' run from one of these jobs were collected. Twenty-four men and a ⅓ yd. Smith mixer of the dumping type were able to place 94.1 cu. yds. or 470 sq. yds. of 9-ft. road 7 ins. thick at a total cost of $364.41, exclusive of cost of grading and interest and depreciation on equipment. The materials were furnished free to the contractor on the siding nearest the work and hauled to the job at his expense.

In figuring the cost of the road, the cost of materials to the county was included with the cost of mixing and placing carried by the contractor, and are itemized as follows:—

111.5 bbls. cement	$115.96
93 yds. bank-run gravel	94.86
Water piped from the city	19.27
Baker protection plates for expansion joints	29.07
Coal and oil for engine	4.00
Labor	101.25

This gives a cost per cubic yard of $3.98 and $0.79½ per square yard.

Another piece of construction work for Milwaukee was a road 18 ft. wide and 7 ins. thick. The work was done by 20 men, using a ½ yd. Chain Belt mixer with chute delivery. The water was piped along the road from the city as in the preceding case, but a 4½-h.p. gasoline engine was necessary to force the water up to the head required. The work recorded covered a period of four days and cost $1.128.46, exclusive of equipment and grading. The cost of piping and water for this and the preceding job was fully accounted for in a former paragraph. The cost of the work was divided as follows:—

414 bbls. cement	$430.92
92 yds. sand and 152.3 yds. gravel	340.84
Water	60.20
Baker protection plates for expansion joints	76.50
Coal and oil for mixer and engine	7.50
Labor	232.50

From these figures we arrive at a cost of $4.70 per cubic yard and $0.91 per square yard for the pavement.

In southwestern Michigan a short strip 708 ft. long, 9 ft. wide and 7 ins. thick of 1:2:4 concrete cost $717.83, exclusive of grading, equipment and water. The equipment consisted of a 7-cu. ft. Clover Leaf mixer, necessary wheelbarrows and shovels and lumber for forms. The gang on this road was much smaller than that of any of the other roads. Details of the cost were:—

225 bbls. cement	$234.00
69 yds. sand	37.59
136.35 yds. gravel	196.34
Gasoline and oil for mixer	10.00
Baker plates	96.00
Labor	144.00

This gives a cost per cubic yard of $4.68 and per square yard of $0.91.

In the west central part of Michigan 2,580 ft. of concrete 9 ft. 2 ins. wide and .55 of a foot thick were constructed by a township as an experiment. A gang of 12 men using a 7-cu. ft. side delivery Koehring mixer did the work for a total cost of $3,302.62, divided approximately as follows:—

746 bbls. cement	$ 870.00
655.9 yds. sand and gravel	553.28
Baker protection plates and filler	170.12
Labor	1,690.50

These figures give a cost of $7.28 per cubic yard or $1.31 per square yard. Had the cost of grading, excavation and culverts been added to the above, the cost of pavement would have been increased to $8.73 per cubic yard or $1.46 per square yard.

The following work was constructed in the north central part of Illinois during October and part of November of last year. The road is 5,500 ft. long, 12 ft. wide and has a uniform thickness of 6 ins. The total cost, not including water, macadam shoulders and equipment, was $7,089.42. The equipment consisted of a ½ yd. Koehring mixer, road grader, plows, scrapers, road roller and the necessary wheelbarrows and shovels. The cost was as follows:—

2,274 bbls. cement	$2,333.65
720 yds. sand	582.40
1,185 yds. gravel	1,787.03
Operative cost of mixer	51.99
Baker plates and creosoted wood blocks for expansion joints	160.03
Labor	2,282.52

The total of these figures determines the cost per cubic yard as $5.80 or $1.06 per square yard. No information was obtained on the cost of water for this work.

METHODS OF ESTIMATING STREAM FLOW WHEN STREAMS ARE FROZEN.*

By W. G. Hoyt.†

The usual methods of obtaining daily discharge of streams under open-water conditions may be briefly given as follows: Daily gauge heights are obtained from a gauge maintained at a permanent datum. Current meter measurements are made to determine the flow at different stages of the river. The results of these measurements are plotted with gauge heights as ordinates and discharge in second-feet as abscissas. A curve is drawn through these plotted points and the daily discharge is obtained by applying the mean daily gauge heights to the curve. If the channel is fairly permanent, such a curve will remain constant and measurements made from year to year will plot in close proximity to it.

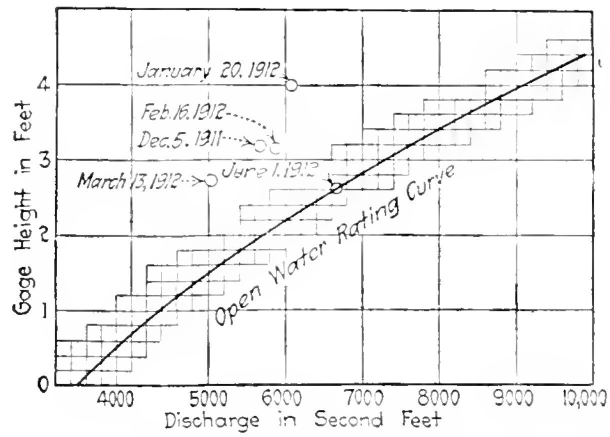


Fig. 1.—Open-Water Rating Curve for Rainy River at International Falls, Minn.

(The curve is based on a large number of current meter measurements and plotted winter measurements showing how relation between stage and discharge is destroyed by ice conditions).

When the temperature falls below freezing, numerous conditions affecting stream flow are liable to be produced which tend to destroy the otherwise fairly constant relation between stage and discharge, thus making it necessary to employ special methods to arrive at the true daily discharge. (Fig. 1.)

Measurements of discharge which indicate the flow at the time they are taken are fundamental in any method for winter estimates. The accuracy of the results will depend largely on the frequency of the measurements, and, in connection with records of gauge heights, temperature, precipitation and ice conditions, they form the basis for estimates of flow.

Precipitation is the cause of all run-off, and since temperature is the controlling factor in regulating the rate at which winter precipitation reaches the streams, it follows that temperature is, in general, the most important governing factor and should be given special consideration in making winter estimates of runoff.

Estimates of stream flow under winter conditions may be made by the following methods:

* Abstract of work of the United States Geological Survey.

† District Engineer, Water Resources Branch, United States Geological Survey, Old Capitol Building, St. Paul, Minn.

1. By the application of the gauge heights of the water surface to the open-water rating, when it is known that the controlling point for the gauge is clear of ice and that no backwater exists at the gauge.

2. By developing a curve based on discharge measurements and gauge heights to the water surface to which is applied directly the open water-gauge heights as taken by the observer.

3. Basing the flow directly upon discharge measurements, taking into account the climate, ice conditions and gauge heights.

(a) By the eye method, working directly with the daily discharge, varying it between times of measurement by inspection of the temperature and precipitation records and gauge heights, and adjusting by comparison of results for nearby stations.

(b) By applying the open water rating to the gauge heights and applying to these discharges a coefficient as determined at times of measurements, varying the coefficient according to a knowledge of temperature, precipitation and ice conditions.

Fig. 3.—Suggested Form of Special Computation Sheet for Records and Estimates of Stream Flow Beneath Ice.

(c) By the graphic method, plotting the records of temperature, precipitation and gauge heights to the water surface and determining the amount of correction necessary to apply to the gauge heights in order that the open-water rating table may be used, basing the variation in this correction between times of measurements directly on the variations in gauge heights and temperature conditions and modifying the same by record of precipitation and ice conditions.

The accuracy of Method 1 depends primarily upon the location of the station. Stations are now located at several points in the United States and Canada at which this method is giving excellent results, but, as their number is few, the method can only be used in special cases.

The accuracy of Method 2 will depend largely upon the number of discharge measurements and their conformity to a true curve. It is believed that this method can be used at former stations than can Method 1.

The methods described in No. 3 will apply at practically all gauging stations which are affected by ice conditions. Method 3 (a) is the one now commonly used, but it is believed that 3 (b) and 3 (c) will give better results than 3 (a) and that Method 3 (c), which is described more fully hereafter, has an advantage over either 3 (a) or 3 (b).

A discharge measurement taken under ice conditions, when plotted to the open water gauge heights (Fig. 1), will always plot either on the open water curve or to the left, showing that the disturbing conditions result in a backwater effect. Therefore, to arrive at the true flow for a given gauge height it is only necessary to determine the magnitude of this backwater effect at the gauge. Since the formation of ice is due entirely to climatic conditions, it follows in general that the amount of backwater varies directly with climatic conditions.

Having determined accurately the amount of backwater at stated intervals by discharge measurements, it is possible to determine the backwater effect between times of measurement by constructing a curve of backwater. Such a curve can be drawn by following the observed gauge heights and the climatic and other conditions which cause the backwater.

The development of this method has been largely based on studies made during the winter of 1911 and 1912 on the Rainy River, at International Falls, Minn. At this point there is a regular current meter gauging station just below the plant of the Minnesota and Ontario Power and Paper Company. The Canadian Department of Public Works determines the flow at the plant by means of wheel ratings and the same flow is also computed by the United States Geological Survey at its regular gauging station. The average monthly variation in flow, as determined by these two methods during the five months from June to October, 1912, was 0.75 per cent.

The Rainy River, for some miles below the power plant, has a very slight slope, so that notwithstanding the fact that this part is usually free from ice, due possibly to the presence of acid from the paper mill and to the agitation of the water as it passes through the wheels, there is more or less backwater effect due to the formation of ice which occurs below the open water stretch.

We have, therefore, at this point a gauge station which is so affected by ice that the regular methods of computation of daily discharge do not apply, and also a station where the true daily flow is obtained, so that data are available for studying the effect of the ice. This study has been made graphically on Fig. 2, which shows the following curves:

1. The observed daily gauge height for the gauging station below the dam.

2. The corrected daily gauge height obtained by using the rating table for the station below the dam and finding the daily gauge height corresponding to the daily discharge given by the records of flow through the plant (no water passes over the dam).

3. The mean daily temperature at the gauging station.

4. The daily precipitation at the gauging station.

5. The daily backwater effect obtained by taking the difference between the observed and corrected gauge height curves, which shows the amount which the recorded gauge height reading should be corrected to give a gauge height which will, when used with the open water rating table, give the true discharge.

A study of the mean temperature curve and the backwater curve shows that these two curves tend to follow the same general direction, which confirms the assumptions previously stated. This is also borne out by records at other stations, and it is therefore believed that this relation will hold on the average steam, unless it is destroyed by unusual precipitation or ice conditions; that is, ice jams which cannot be taken into account in the construction of the backwater curve.

Based on this assumption, it is possible to construct the backwater curve from a comparatively few measurements of

discharge distributed through the period affected by ice from which the backwater effect on the days on which they are taken can be obtained. By plotting these values as ordinates and days as abscissas under a daily temperature curve, it is possible to draw a curve through the point so plotted, following the same general shape as the temperature curve, which will give the backwater conditions for each day. In drawing this curve, account should be taken of the daily precipitation and of ice jams or other unusual conditions which may introduce backwater effect.

The circles plotted with the backwater curve (Fig. 2) show the backwater as determined from the discharge measurements on various days during the period in question. If these and the temperature records had been the only data available, a backwater curve could have been drawn which would have approximated the true backwater curve which was obtained from the daily records of flow over the dam. Of course care must be taken to study all the possible conditions which may affect the estimates.

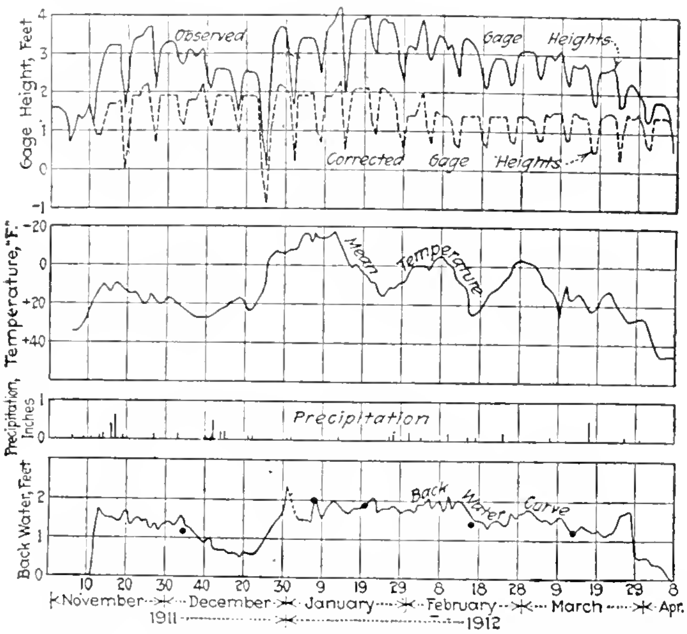

Fig. 2.—Various Observations at Rainy River Gauging Station, International Falls, Minn., November 1, 1911 to April 8, 1912.

(The observed gauge heights have been corrected on the basis of the backwater curve. The mean temperature was averaged in 5-day periods. The backwater observations were taken at the gauge. The full circles on and near the backwater curve indicate dates of current meter measurements).

Aside from giving more accurate results, this method has an advantage over any other method that has been devised, in that it gives a complete record of all the steps taken, so that the estimates may readily be reviewed or checked by a second person and show at once exactly how they were prepared.

The data necessary for use with this method are:

1. Daily gauge heights observed to the water surface through a hole made in the ice if the section is frozen over.

2. Records of daily temperature at the gauging station.

3. Record of mean precipitation over the drainage area above the gauging station.

4. Measurements of discharge* at intervals during the period when frozen conditions existed.

*See "Engineering News," Sept. 12, 1912, for methods of making.

As already stated, the accuracy of this method will depend upon the frequency of these measurements. If the winter conditions are more or less constant, less frequent measurements will be required, as it is during periods of thaws that the principal uncertainties occur. Regardless of this method, a special computation sheet should be used and some fairly standard method followed, which will bring winter estimates on a standard basis so that full records may be had. The headings on the typical card given in Fig. 3 are suggested for such a form.

In connection with this study, I wish to advance the following tentative conclusions, based upon observations of conditions in Minnesota since the fall of 1911:

1. Ice conditions usually cause backwater at the gauge.

2. Backwater increases rapidly at the beginning of each cold period, partly dropping off later.

3. The amount of backwater will tend to vary with the temperature.

4. Stream flow will drop off suddenly, following a cold period and will be partly regained later.

5. Stream flow tends to decrease when temperatures go below 32 degrees, but the flow tends to increase with any rise in temperature, especially when the minimum temperature goes above 32 degrees Fahrenheit.

6. A snow cover on the ice may cause increased backwater.

7. Flow may increase without a rise in gauge height, due to the wearing away of the ice.

SOME CANADIAN WATERWORKS STATISTICS.

On the average each person in Canada served by waterworks uses 113 Imperial gallons of water a day and pays $4.12 a year for it.

New Brunswick has the highest per capita consumption in Canada, viz., 161 gallons per head per day, while Manitoba and Saskatchewan have the lowest—46 gallons per head per day. The more general use of meters in the western provinces reduces waste and keeps the per capita consumption down to about the same amount as in European countries. The people of Manitoba pay the highest per capita rate for their water—$6.27 per year, while those of New Brunswick come next with a per capita cost per year of $4.82.

The following table shows the estimated cost per 1,000 gallons, the estimated cost per capita, and the daily consumption per capita:—

Province.	Estimated cost per 1,000 gal. (cents)	Estimated cost per capita per year (dollars)	Daily consumption per capita (Imp. gal.)
Nova Scotia	7	3.76	147
Prince Edward Island	16.4	2.87	48
New Brunswick	8.2	4.82	161
Quebec	9.5	3.92	113
Ontario	9.6	4.21	120
Manitoba	20.6	3.46	46
Saskatchewan	23.	3.86	46
Alberta	13.	6.27	132
British Columbia	8.2	3.44	115
Canada	10	4.12	113

CONTENTS OF THIS ISSUE.

THE DEVELOPMENT OF FORT WILLIAM AND PORT ARTHUR.

In connection with an article in this issue on Dock Construction in Fort William and Port Arthur few people realize that these twin cities, located 1,700 miles from the Atlantic and 1,000 miles from the Pacific, and practically midway between our Atlantic and Pacific coasts, have, nevertheless, eighty per cent. of the total land area of the Dominion lying westward of them. The wealth of natural resources and the gigantic coming development of the great western portion of the Dominion are too well known to need comment here. The last harbor in Canadian territory westward of our Great Lake systems, it was the Canadian Pacific Railway, with its creation of the twin cities as a transfer point between rail and water traffic, that gave them their first hopeful outlook as an important locality. Previous to that, the route to the west was by water past Fort William and Port Arthur to Pigeon River, thence by Rainy River and Rainy Lake to Kenora. Of late years the making of Fort William into a first-class harbor and the tying up with it of the Grand Trunk Pacific and Canadian Northern Railway systems seems to assure its future in no uncertain terms.

It is doubtful whether the Hudson Bay route for the transports of the products of the West to Great Britain will ever prove as practical and feasible as some of our governments and optimistic citizens seem to think. Moreover, notwithstanding the construction of the Panama Canal and any subsequent diversion of Western traffic by that route, there must always be a tremendous traffic by rail and water between the east and west that will tax the capacity of the railways to the utmost and build up any cities which are located at the point of transfer into places of great activity. There have been signs, however, that Fort William and Port Arthur will not have to depend for their progress and importance solely on their location as the junction point of great rail and water transportation systems. It is true the transportation business at the head of the lakes requires the energy of 5,500 men, whose pay-roll amounts to over three million dollars to handle same, but important manufactures are also there. In 1912, the Canadian Car and Foundry Company started to erect a plant which guarantees to give employment to one thousand men for the first five years. Numerous other manufacturers, including the Atikokan Iron Company with a blast furnace of 200 tons per day capacity are there located. In great measure the citizens have to be grateful for the presence close to their doors of three great water falls capable of developing about 145,000 horse-power and of supplying energy to consumers at a cost ranging from fifteen to twenty-five dollars per horse-power per annum. At the Kakabeka Falls, close to Port Arthur, 45,000 horse-power has already been developed, and more energy, as we stated, is within easy reach.

The twin cities of Fort William and Port Arthur and their citizens are bound to witness paralleling their own expansion more of the material signs of the growth of Western Canada than probably any other city in Ontario. The northern shores of Lake Superior, with the exception of possibilities from the opening and establishment of extensive and great mining camps, does not, as far as nature is concerned, hold out much hope for the growth and support of a busy and modern city of large population. The development of Port Arthur and Fort William into such is a welcome sight, and is another striking illustration of the attending constructive results

of modern transport and railway systems in giving impetus and opportunity for the settlement and development of civilization in localities where otherwise nature is so inhospitable as to have delayed for many long years any extensive inroad of civilized population.

THE UTILIZATION OF WASTE ROAD SPACE.

It has been very truthfully said that this is an age distinguished for its utilization of waste products. Wonderful advances have been made in this direction, and are being made every day. The utilization applies, however, more to the cities and their manufacturing industries than it does to the country's natural resources. In the partly settled regions of the country especially, one finds waste so enormous as to far offset beneficial gains in other ways.

Travelling through our Canadian forests, for instance, even where fire has not wrought havoc, one cannot help being impressed by the waste of fallen and rotting trees around, whose wood, as fuel, if obtainable to the inhabitants of the slums of nearby cities, would be a blessing and benefit. Our highway system might also be classed as a waste of considerable magnitude.

Consider country roads. The general width of a "right-of-way" is sixty-six feet. Of this sixty-six feet, the road proper, with the ditches, occupies from twelve to, say, twenty-two feet. That leaves two-thirds of our "right-of-way," or five and one-third acres per mile, unutilized in any beneficial way. In fact, in as far as many road sides are usually a mass of weeds, whose seeds are blown and carried on to neighboring farms, they might be said to be an active agent for harm to the community.

In Europe, the better roads are laid out with grass sown on each side and in many places fruit trees, whose products, handled by the Government, goes a long way towards paying for the up-keep of the roads. Very few people would consider it possible in America to ever grow fruit trees by the roadside and expect to harvest any products from same. Sad to relate, it would probably be looked upon by the travelling public of this continent as some philanthropic scheme for the easing and benefit of their gastronomic proclivities. It would still leave the problem of utilizing waste road sides in this country in some economically beneficial way unsolved. Unless, however, one can devise such means, the returning or renting (fencing off, if necessary), of unused portions of our country roads to those who will cultivate and put them to beneficial use, their ownership becomes a serious responsibility. Consider an ordinary township, divided into thirty-six sections, with a sixty-six foot road allowance between each, the road acreage amounts to 572.4 acres. If one allows twenty-two feet for actual width of ditches, etc., then there is left two-thirds of the acreage, or 382 acres, of land wasted per township. Figured out, it would probably be within facts to state that ten or twenty millions of acres will be lost as productive land to the communities of Canada and the United States if the side widths of road allowances be not utilized.

Country roads on this continent originally needed a highway allowance of sixty-six feet, mainly because, being in a forested country, it was necessary to protect travel and the roadway from falling trees, forest fires, etc. A width of sixty-six feet, with the road in the centre, under those circumstances, was very advisable. As land becomes cleared, outside the benefits of a former roadbed, one fails to see why it would not be advantageous that the roads should be constructed solely in the right or left portion of the "right-of-way." Such a course would leave a strip forty-four feet wide, which, with a single fence, might well be rentable or workable, and so reduce the cost of road maintenance itself.

It would certainly seem advisable, for the sake of providing for possible future increase in traffic, that all highway appropriations should continue to be the full sixty-six feet of width. The need, however, of highway associations seriously solving the problem of making their spare road area productive is one that will grow with age, and there appears in it a considerable and unappreciated opening to save some of the cost of road maintenance to the interested tax-payer.

EDITORIAL COMMENT.

An instance of the beneficial work being accomplished by the International Joint Commission on Waterways between the United States and Canada has lately come to hand in a decision handed out by the Commission in regard to the proposed dam to be built in the Detroit River at the head of the Livingstone Channel. This ship-channel is partly in Canadian and partly in American waters. Deepening the upper part of the channel, it was thought, would have the effect of lowering to some extent the depth of water in the river above, and to correct this a dam to Blois Blanc Island on the Canadian side was to be built. The Canadian town of Amherstburg complained that it would injure their water front, and the question was referred to the Joint International Commission. The American interests urged the necessity of the dam to safeguard the enormous traffic up and down the Detroit River, and in this regard it might be mentioned that the tonnage on the Detroit River in 1912 reached the amazing total of ninety-five million tons, or over four times the amount of tonnage passing through the Suez Canal. The value of these shipments aggregated 80 million dollars. The decision recently handed out by the Commission in regard to the dyke which the town of Amherstburg objected to, proposes to substitute a dyke on the west side, which will have practically the same effect in safeguarding navigation while it will overcome the objections of the town of Amherstburg.

The Commission has been busy all spring on many internation questions, and is to be congratulated on the splendid work it is doing.

ELECTRIFICATION OF PANAMA RAILROAD.

Now that the relocation and reconstruction of the Panama Railroad is completed surveys are being made for the transmission of power for the operation of the line by electricity. The Gatum hydro-electric plant which is under construction will supply the energy required under normal conditions, but there will also be a connection with the present steam-driven electric plant at Miraflores. The transmission voltage will be 44,00, and this potential will be stepped down at various distribution centres for running the trains, lighting the canal, and supplying the power required for operating the various machine shops, the gates, and other appliances at the dams and locks. Bridges of the customary type for carrying the cables, etc., will span the tracks, the distance between them varying from 200 ft to 300 ft., according to the local curvature conditions of the railroad.

THE CAUSE AND DETECTION OF WATER WASTE.

The property owner pays for water waste in two ways. He pays in the form of a higher tax rate, for new watersheds, reservoirs, tunnels and pumping plants which are necessary to meet the demands caused by waste, and he pays for the waste in his water bill.

People think the water supply as plentiful as the air supply. They give no more thought of water dripping from a faucet not in use than they do to the breath they exhale. They don't know that a drip 1/32 of an inch in diameter, estimated on the meter value of water, represents in a year the loss of $11.68. They let their faucets drip, let their pipes leak and give no heed. There is plenty of water.

However, as population increases, water consumption increases and water supply decreases, and more and more it becomes necessary to seek new sources of supply, to build new reservoirs. Water famine rears its ugly head. Then they recognize that water should not be wasted and that where waste continues there must be compulsory conservation. City authorities force property owners to put meters in their buildings with a view to decreasing waste by penalizing the owner for allowing waste. He pays the penalty in the form of an increase in his water bill.

Take New York City, for example. Thanks to its prodigal water waste, taxpayers must pay $260,000,000 for a new system of supply, $10,000,000 more for a tunnel to carry it from the reservoirs and the constantly mounting cost of the upkeep of the system. When the time comes for the distribution of the new supply, new pipes must be laid in the city streets, for the old pipes will be unable to withstand the pressure. Likewise, new pipes must be laid in the buildings. And the taxpayer will see the cost of the new city mains reflected in his tax bill and will give the plumber more money for putting new pipes in his building.

If New York's water supply had been properly conserved, storage reservoirs, built at a cost of $50,000,000 or $60,000,000, would have furnished a sufficient supply, even though two years passed without a rainfall.

But even with the precautions which have been taken, the waste is still going on, and it is to the interest of all taxpayers, unless they wish to give up another half billion a few years hence, to make it their individual business to see that there is no waste of water in the premises which they own or occupy.

While it is held that all property using water should be metered and that the criminal or neglectful waste will not stop until this is done, it is not the purpose to discuss that subject here. It is intended to bring home to the individual property owner or lessee the fact that he can reduce his expenses and conversely increase his dividends by paying attention to water waste. A leak in a pipe is a leak in the pocketbook.

At the present time in New York all buildings used for business purposes are metered, as are buildings above a certain height used for dwelling places. All other property pays for its water on a frontage basis, that is, the charge is based on the number of front feet in the property and the number of water closets, bathtubs, etc., served. There is no way in which the city can detect the waste of water on premises which are rated on a front-foot basis. The man who pays on a meter basis pays for the front-foot waste because the meter rate is higher. Where the service pipe or trap (the city's pipe) is an inch or more in diameter the premises are supposed to be metered.

The meter rate, $1 per thousand cubic feet, averages much higher than the frontage rate, but despite this, proper supervision will make the water bill of the average metered property lower than that of the overage front-foot premises. The average consumption of water in a metered apartment house containing one or two water closets and bath, is 1,500 cubic feet per month per family. This does not include, of course, water used by the house plant for boiler, steam or refrigerating purposes. In a metered tenement house where there are no baths and water is used principally for domestic purposes and toilets the consumption will average 500 cubic feet per month.

In premises used for mercantile purposes the average consumption is difficult to determine, varying with the industry pursued. The same condition obtains in hotels and office buildings by reason of the fact that the occupancy of the rooms and the number of people in them are constantly changing.

In unmetered apartment houses there is a waste, on the average, of fifty per cent. of the supply sent through the pipes. This is due to negligence in caring for plumbing fixtures and delay in repairing leaks. The waste caused by leaks in water closets in unmetered apartment houses averages from 14,000 to 20,000 cubic feet a month, or a monetary loss, on a meter basis, of from $14 to $20. Underground leaks, overflowing roof tanks and the carelessness of tenants who leave taps running are additional contributors to the volume of waste. Some property owners assert that it is cheaper to let the water waste than it is to pay the plumber's bill. Although they may not realize it, these property owners are paying for the waste in their tax bills, but is it just to those who are paying the higher meter rate that they should also be compelled to pay for the waste caused by the owner who, in his ignorance and greed, says, "Oh, let it run, it doesn't cost me anything?"

Unless there is a marked increase from month to month in his bill the average owner of metered property is content to pay and take no steps to ascertain if he is getting what he is paying for. Or, perhaps, there is a small increase in his bill for a certain month. He pays no attention to it. The next month there is a still larger increase and he calls a plumber to investigate. The plumber finds a leak. But the owner must pay for the water he has not used. If this owner had in his employ an expert supervisor who knew what amount of water should be used, who could read the meter registerings intelligently and detect leaks before they became a charge on the property, the value of his services would soon become apparent in the decreased cost of maintenance.

An instance is known of a bill for $900 for water used in seven months in a seven-story metered apartment house, sheltering twenty-one families and including a store. Investigation revealed a leak due to a defective valve in an underground pipe on the house side of the meter. After the valve had been replaced by a new one the water bill for six months' consumption was $320. Since that time the total yearly bill has been $740.

In a factory building where the consumption was nearly 33,000 cubic feet per month the owner erected a roof tank to give a better supply to the upper floors. The consumption at once jumped to 110,000 cubic feet a month. The plumber neglected to put a ball float in the tank and the result was that the extra pressure at night, due to the fact that the supply was not being used, caused the tank to overflow. When the overflow and the cause were revealed the proper steps were taken to remedy them, and in the next three months the consumption dropped to 33,000 cubic feet per

month. The services of the expert cost $20 or $30. The owner saved $77 and guaranteed himself against continuing to pay for water which he did not use.

In a certain hotel the water was used for refrigeration in twelve ice boxes. The consumption was between 150,000 and 190,000 cubic feet per month. The owner called an expert who told him something was wrong somewhere and that a thorough investigation should be made. The owner took no action. but the meter did and the water bills continued to grow. Finally he ordered the investigation. The expert found that water in a 2-inch overflow was running directly into a sewer. It couldn't do anything else by reason of the construction of the ice machine. A new machine put the consumption where it should be. How did the expert know something was wrong? Because he knew that in the adjoining building, also used as a hotel, a larger building containing more rooms and occupants, and therefore using rightfully more water than its neighbor, the consumption was only 150,000 cubic feet a month in the coldest weather, and in the summer as low as 115,000 cubic feet.

In a certain downtown office building, having an engine room equipment of the highest efficiency, water bills were found to be increasing regularly for the supply used on the upper stories. At the beginning of the expert's investigation the consumption was 15,000 cubic feet a day. He found that a number of toilets on these floors were leaking steadily day after day. His recommendations for the repairing of fixtures were carried out and the consumption dropped to between 7,000 and 9,000 cubic feet a day.

Note that in the instances cited the owner is paying $1 for every thousand cubic feet of water wasted; also saving $1 on every thousand cubic feet not wasted.

In another large office building there is a restaurant on the ground floor. The lessee put in an ice machine which was consuming apparently, when the expert was called in to explain why the water bill was so large, 395,000 cubic feet per month. The expert found that the ice machine from 7 p.m. to 6 a.m. was throwing water into a tank which overflowed. The expert showed a method by which this water could be utilized for other purposes than refrigeration and the waste stopped, and at the end of thirty days the consumption had been reduced to 135,000 gallons, the lessee was getting greater service from less water and had reduced his bills by $260 a month.

The owner of a tenement house having outside water closets found his water bills increasing steadily. He called in the expert, who found that defective hoppers, anti-freezing toilets and fixtures in a bad state of repair and general neglect were causing a large waste. In one closet showing a defective hopper the water was running into the ground through a hole in a sewer pipe. The meter was registering 35,000 cubic feet per month. After the proper repairs had been made the registration was from 1,500 to 2,000 cubic feet per month.

In the average metered business building experience has shown that water closets will waste, on an average from 14,000 to 19,000 cubic feet per month. In a prominent restaurant the water consumption had been between 9,000 and 10,000 cubic feet per month. A leak in a toilet jumped this consumption to 39,000 cubic feet in a month. When it was repaired the consumption returned to the first figure.

The causes of waste are many, and only an expert who is constantly meeting with their variations can determine their exact nature. In a large bread manufacturing plant the consumption, without apparent cause, leaped from 285,000 cubic feet a month to 587,000 cubic feet. The expert called to investigate found that while there were several points of waste the bulk of it was due to the forming of vegetation on an outside condenser used for refrigeration. The growth prevented the water from exercising its normal cooling power on the apparatus, so that more water had to be used to achieve the result that had formerly been brought about with a smaller quantity. The recommendations of the expert were carried out and the consumption reduced to about 200,000 cubic feet per month.

The examples herewith cited, all of which are taken from actual records, amply show that the average property owner or lessee is making a good investment in engaging a competent individual or firm to inspect his water supply plant throughout the year; to take full charge of water bills and make repairs to fixtures or pipes whenever they become necessary. The owner or lessee seldom has the knowledge and experience necessary to enable him to ascertain the one or more causes which produce water waste, even if he could spare the time demanded for a thorough investigation. The owner, as a rule, must rely on his agent to detect and correct conditions which cause waste. The agent, for the most part, depends on the superintendent, the engineer or the janitor of the premises, and no one of these three is usually sufficiently versed in the knowledge and experience, without which he will seek in vain for an explanation of why the owner is called upon to pay for more water than he is using.

A most striking example of how difficult it is to locate some leaks, and how thoroughly all means of determination must be employed to get at the truth, is shown by the following instance:—

In a manufacturing plant situated beside the water front a certain meter began to register a large increase in the amount of water used. The owner told the expert that there had been no actual increase in his consumption. A test of the meter, which was one of several, some of them being connected, showed that it was registering properly. In other words, the amount of water it registered was passing through the pipes. All the other meters and pipes were tested, but the instruments failed to record a leak. Yet the expert felt sure there must be one somewhere. He told the owner to shut off all the water. This was done, but the meter in question continued in operation, still registering a flow at the rate of 31,000 cubic feet a month. All water had been shut off, but here was water running There was only one thing to do—lay bare every bit of pipe connected to that meter. When the diggers had completed their work, a leak was found on the under side of the pipe. The water was spurting into the river without giving any sign of a leak.

STEEL FOUNDED RAILWAY CROSSING.

In most cases it is difficult to maintain a track efficiently at grade crossings owing to the tendency of the traffic to shift the crossings out of position and to crush the ballast that supports it. An interesting development in this connection is the use of steel longitudinal members to carry the rails at the crossing, connected so as to form a unit structure and to maintain the rails in the proper position. This system has been applied to a grade crossing at Muncie, Ind., where a singe track electric interurban railway crosses two parallel main tracks of the Cleveland, Cincinnati, Chicago, and St. Louis Railway on a curve having a radius of 17-07 ft. The daily traffic averages 64 electric cars and 18 steam trains. Each rail is carried on two 6-in. channels spaced 16 in. apart, and laid longitudinally with the flanges outward, connected at the bottom by 4 in. by 5-16 in. straps 2 ft. apart, and at the top by a continuous 5-16 in. plate 20 in. wide.

NORTHERN ATLANTIC SHIPPING

Hon. J. D. Hazen, (minister of marine and fisheries), replying to a question in the house of commons, remarked that the Imperial Board of Trade, had concluded arrangements for reporting the location and the movements of ice along the route of trans-Atlantic steamships during the spring months. This announcement is one of very great importance to shipping interests. The Titanic disaster of last spring and the subsequent inquiry respecting it made the desirability of this step abundantly clear. For this purpose the Scotia was despatched on the 8th instant to latitude 44° north, longitude 60° west, with instructions to report on the way any ice met and also to endeavor to note its southern limit. After having done so, the Scotia will proceed to St. John, Newfoundland, noting and reporting ice conditions met with. While at St. John, the Scotia will get into communication with all wireless stations on the Newfoundland, Labrador and Canadian coasts, and as accurately as possible ascertain existing conditions and the direction in which the ice has commenced to move. From St. John, the patrol boat will proceed to and report the southern limit of the drifting ice. Having located and reported the southern limit, the patrol will be northward to report icebergs or field ice along the coast of Newfoundland, and as far as Hamilton inlet.

The patrol is specially charged to be vigilant in the observance of ice nearing the steamship routes. The chief object of the expedition is to give warning to the steamship lines of the probable quantity of ice that will be in the vicinity of the track, and to give them any information that will assist them to form a judgment as to the advisability of giving any instructions for the greater safety of their vessels. On board the Scotia there are three scientists, the senior of whom will direct the movements of the vessel. They will take observations of the directions, velocity and depth of currents, together with the temperature and salinity of the water. In addition, meteorological observations of the upper air, including the investigation of the currents and temperature, will also be carefully taken. Acting in conjunction with the board of trade, I have concluded an arrangement whereby all messages from the patrol boat will be forwarded to the signal office at Quebec and from there promptly furnished to all interested parties. In this way the shipping interests at all the river St. Lawrence and Atlantic ports will be kept informed of the prevailing ice conditions.

To supplement the work done by the Scotia under the direction of the board of trade, I have made arrangements whereby the Marine and Fisheries Department will, immediately after the opening of navigation on the River St. Lawrence, despatch the C.G.S. Montcalm to patrol Cabot strait, at the entrance to the gulf, from Sydney harbor to the south coast of Newfoundland.

The location and movements of the ice in this region will be reported and full information will be furnished daily, or more frequently if found necessary, to the steamship companies. I have also arranged that Professor H. T. Barnes, of McGill University, who has, during the past several years, conducted experiments on one of the departmental steamers, shall be on board the Montcalm while performing this patrol service in Cabot strait. By means of his invention, the microthermometer, Professor Barnes has demonstrated the possibility of determining the approach to ice by any vessel equipped with his apparatus. Eager to avail myself of any scheme that promises to further safeguard navigation to the River St. Lawrence, I have directed that Professor Barnes, with a staff of assistants, shall join the ship in order to further demonstrate the utility of the invention, and with a view to its general adoption by shipping interests.

THE USEFULNESS OF COUNTY ENGINEERS.

The economic need of highways has been recognized on every hand, but the provision of a workable method for building them is not so easy to pass judgment upon. In the March issue of The Iowa Engineer Mr. F. R. White and Mr. J. H. Ames, assistant engineers of the Iowa Highway Commission, discuss under a heading "Is a County Engineer Necessary?" the need and advantages of county work which has an engineer at the head of it. A portion of this paper is abstracted and published below.

As a basis of comparison, let us consider the mileage of some of our largest railway systems to the mileage of our state public highways. The Chicago & Northwestern Railway has 9,700 miles of track, and the Chicago, Milwaukee & St. Paul Railway has 8,000 miles of track, or either of these great systems has less than one tenth of the mileage that Iowa has in her public highways. Going a little farther, we find that the ten largest railway systems in the United States have a combined mileage of 103,000 or an amount approximately equal to the miles of public roads of this state.

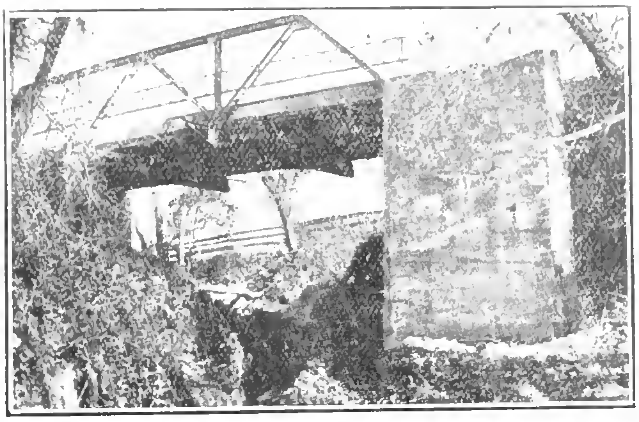

Fig. 1.—This 40-ft. Steel Span on 20-ft. Abutments has a Drainage Area of Only 69 Acres. Cost $5,187.

Of highways, perhaps not more than fifteen per cent. are what might be called "main travelled" roads. In improving our highways these main travelled roads will necessarily be the first to be given consideration. When we consider the amount of money to be spent upon this primary system of highways in order to properly provide for the present and anticipated future traffic, we are astounded at the enormity of the undertaking. In the average county in the state the cost of grading, draining, and gravelling the roads will amount to about $2,500 per mile. The cost of improving the 15,300 miles of such roads will be about $38,250,000 or an average of $386,500 per county. This includes only the "main travelled" roads, and does not take account of the amounts which the townships will spend on the township road systems.

No accurate statistics are available regarding the number of the bridges in Iowa. Adair county in the southwest part of the state has 4,200 bridges, of which over 2,000 are twenty-foot span or above. The majority of these 4,200 bridges are of more or less temporary nature and will require attention soon. Polk county has 930 bridges with an average span of 34 feet. Seven hundred and fifty of these bridges are at the present time either wood or steel, and are in very bad condition. This county has spent over $300,000 in the construction of 265 concrete structures which have an average span of 10.5 feet.

From the statistics available it appears that the average county has approximately 1,600 bridges. The average cost

of replacing these structures with permanent work as shown above will be about $1,000 per bridge, or the total cost for building all the bridges of permanent construction will amount to $1,600,000 per county, or for the ninety-nine counties in the state the cost of permanent bridges will be about $158,400,000.

The state has expended in the past year, approximately $7,500,000 on roads and bridges; an average of $76,000 for each county. The proportionate expenditure for roads or for bridges cannot be accurately determined, but the bridge fund for the majority of the counties is close to $30,000 per year. In addition to that, the townships spend a large amount of their road fund on culvert work so that the funds as now spent are about equally divided between roads and bridges.

Any railway operating on sound business principles would have an efficient organization to superintend the expenditure of any considerable amount of money. They would demand complete plans and specifications and records which would show itemized statements concerning every dollar spent. No money would be paid out of the treasury until it could be shown to the board of directors that it was a legitimate expense. To secure these results they would employ an efficient engineering organization to make the surveys, establish the grades, write specifications, draw the plans, superintend construction and keep the construction records clear and straight.

Fig. 2.—A Good Example of Improper Location and Excessive Length of Wing Wall.

Let us compare such an organization with the one in vogue in many of the counties of the state. It is a fact that the majority of the money spent on road work last year was expended without a plan or profile on file to show where or how the money was to be used.

Last season, one county confined the attention of their elevating grader crew to a short strip of road, possibly three miles in length. This work was in a hilly country where much cutting and filling was necessary, yet no survey was ever made of the road. When the work was completed, the superintendent was unable to tell the total yardage of material moved, or what the cost for moving the material had been per cubic yard. Had plans been prepared for this work and accurate cost data kept it would have been particularly valuable to the county in estimating future work under similar conditions. Most of the grading work has been done in such a manner as to provide insufficient surface drainage. Roads are graded and well crowned, yet the side ditch drainage has been incomplete. The water is allowed to collect in low places in the ditches and stand there until it evaporates or soaks into the roadway.

An example of absolute waste of money came to our attention recently. The board of supervisors, together with a number of interested taxpayers, attempted to construct a gravel road approximately nine miles in length. This road was located on low land with little surface drainage. Gravel was hauled upon this road and dumped so as to give a depth of ten inches. No provision was made for either sub-surface or surface drainage. The road was not even crowned before the gravel was placed. Such violation of engineering principles are costly experiments to the taxpayers, and show gross neglect or incompetence on the part of the supervising official.

The loss of money has not been confined to roads alone; investigations show that a very great loss has occurred in the bridge fund. Much of this loss is directly due to the yearly contract system which has been in vogue in many of the counties of the state. Under this system bridge contracts are let in blanket form. They call for no specific number of bridges and no specific location for any bridges bid upon, and as a result, the general design and the location of the structure in the field is left to the supervisor and bridge company's foreman. When such a contract is let, it is impossible to have detailed plans for the various bridges. Where any plans at all are submitted with the bids, such plans are incomplete, and will not fit the varying conditions of the different locations. Consequently when any bridge is built, there is item after item of extra charge for work not called for in the contract. Such charges, for work not covered by the contract, often run the price of the completed work up to a figure far in excess of what the work is worth, or what it might appear from the contract that the total price would be.

As an example of this, the following bill rendered by a bridge company for repairing an old 60 feet steel span is a good illustration.

To building 2 concrete abutments 12 feet deep and encasing old piers:

Building 1 (10-ft. 6-in.) wing, one 11-ft. 6-in., one 25-ft. 9-inch, and one 11-ft. 6-in. wing........	$2,935.00
Driving 11 steel piles at $7.00 each...............	77.00
Lowering old bridge 4 feet and cutting off old cylinders	160.00
Filling north and south sides, including removal of old approaches	184.00
Laying floor and hauling lumber and freight on same to Follett's	36.00
Steel joists for 60-ft. span at $5.50 per ft.	330.00
Lattice railing on span	96.00
Angle to reinforce floor beams for holding joists and drilling floor beams	74.00
	$3,882.00

This bridge after being repaired was yet an old, flimsy, steel bridge with wooden floor, and will have to be replaced in a few years. Under the same contract the county could have built a new 60-foot riveted steel bridge with concrete floor for $3,830.00 or an amount of $52.00 less than the price paid, and this price ($3,830.00) could have been reduced several hundred dollars if a competent engineer had been employed by the county, before letting the contract, to plan and superintend the work.

These specific examples are only a few of the many which occur each year under the present system. It is the direct result of the hit and miss methods of road construction that are costing the counties thousands of dollars annually. We are trying to build roads with only a part of an organi-

zation. We have the "Board of Directors" but have no adequate engineering organization.

Bridges must not be built too small to provide sufficient waterway for passing the run-off from the watershed above them, and in the interest of economy neither should they be made too large.

An example of the result of providing a waterway too small is known. The structure was a 50-foot arch bridge built in 1910. The cost to the county was about $3,000.00. Two years later, or in 1912, the structure collapsed during a freshet, and after the water had gone down it was found that the current had widened the channel by cutting behind the west abutment. As this was a patented type bridge which used the earth pressure behind the abutments to help support the arch, and which has shallow foundations as one of its characteristic features, the result of washing out the fill was the collapse of the structure.

As an example of building bridges too large for the demands of the drainage area, the bridge shown in Fig. 1 is a good illustration. Here a forty-foot riveted steel span with concrete floor and concrete abutments eighteen feet high was placed over a stream having a total drainage area of sixty-nine acres. This bridge cost the county $5,187, when the run-off from the watershed could have been carried by a 4-ft. x 4-ft. box culvert costing about $500. The county in which the bridge is located has an approximate area of 440,000 acres, and at the rate shown above it would cost $32,700,000 to bridge the entire county. The bridge fund in this county is about $30,000 per year, or at the above rate it would require the entire bridge fund for 1,100 years to get once over the county with so-called permanent bridges.

Under the systems usually used in the counties, the general design and the location of the structures are left to the supervisors and to the bridge company's foreman. The majority of supervisors are not trained bridge men, and the bridge company's foreman is not working for the county. As a result there are many examples of improper locations and designs. Bridges are often located several feet above the proper position. In a number of cases we have found concrete bridges located high upon the bank at one side of the stream, and with the pavement or floor six or ten feet above the stream bed. In other cases bridges are so located as to require excessive length of wing walls. In one case, a forty-foot span steel bridge with concrete abutments and three wing walls cost $2,925. This bridge was so located that the other wing wall was made 50 feet long, and the price paid for this wing was $2,262, or an amount nearly as great as the cost of the remainder of the bridge. Another bridge in the same county has one wing wall 80 feet long. This wing extended out into the field, and does not hold up any fill or serve any other purpose which would justify the expenditure of so much money.

In most cases, no estimates are prepared showing the labor and material required to build a given piece of work and when the work is completed the bill presented is allowed by the board without question. This is well illustrated by the record in one county where bills amounting to $57,000 and covering a whole year's work were allowed by the board at one session which lasted not more than three hours. Apparently none of these bills were checked against the structures built as evidenced by the following:—

One of the bills contained the item—

"Building concrete abutments and 2 wings, $737.10."

Investigation disclosed the fact that only one abutment had been built, and that it contained only 15.91 cubic yards of concrete, or the price paid was $46.33 per cubic yard. Another bill for construction on the bridge shown in Fig. 3, contained the item,

"One-half contract price for building concrete bulkheads 16 ft. x 20 ft. long on 48-in. steel culvert 36 ft. long $780.00

The bridge is located on the line between two counties and hence the bill was presumably approved by two boards of supervisors. The bill apparently included only the building of the concrete bulkheads.

Investigation showed that the two bulkheads contained only 15.45 cubic yards of concrete or the price paid was at the rate of $50.48 per cubic yard. According to the engineer who made these investigations, a fair cost for the concrete in each of these jobs would be $12.50 per cubic yard. Another example of the loose system under which the bridge business is handled in many counties is shown by the following invoice:

To one 14-ft. span with 12-ft. foundations.........	$ 720.00
Less acct. abutments 8 ft. deep 8 ft. at $9.00	72.00
	$ 648.00
Lattice railing	$ 28.00
One 16-ft. wing, one 10-ft. and two 8-ft. wings.....	382.00
	$1,058.00

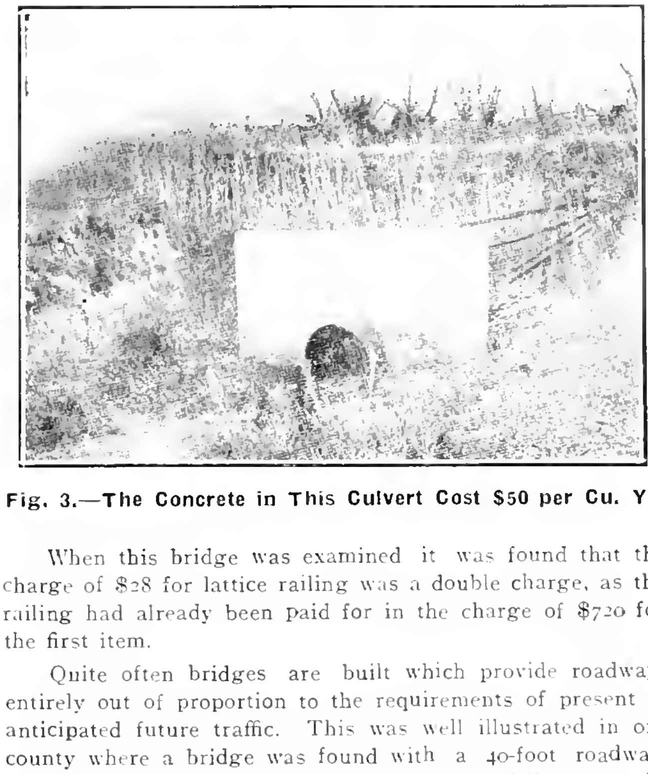

Fig. 3.—The Concrete in This Culvert Cost $50 per Cu. Yd.

When this bridge was examined it was found that the charge of $28 for lattice railing was a double charge, as the railing had already been paid for in the charge of $720 for the first item.

Quite often bridges are built which provide roadways entirely out of proportion to the requirements of present or anticipated future traffic. This was well illustrated in one county where a bridge was found with a 40-foot roadway. The location was such that an addition of filling over the culvert at some future date was impractical. The fact that the bridge was upon a road seldom frequented made this width of roadway very excessive. Not a mile from this bridge, on an adjacent road with a great deal more traffic was another bridge with an available roadway of less than twelve feet. Had a study been made of present and future traffic conditions on these structures, they would never have been built as we found them.

Frequently it is possible to relocate a road and thus avoid building one or more bridges. The following is given as a typical example. In one of the counties, a new road about three-quarters of a mile long was established in such a location that two forty-foot bridges, costing over $2,000 each, were required, when, by a slight relocation of this road, such as any engineer would make, both of these bridges

could have been avoided at a saving of nearly $4,000 and a better road secured.

In some of the counties we have found conditions for which the county boards alone are responsible, yet, in the majority of cases the state is a partner with the county boards in the mismanagement of our highway funds, owing to the fact that inadequate laws and an insufficient organization have been provided for handling the work. Road building is a business and not a side issue to the management of a large farm, or extensive business enterprise. It is hardly fair to a farmer or business man to elect him to the office of county supervisor where he has the spending of thousands of dollars annually in a kind of work with which he is not familiar, and then not provide him with the assistance of men trained in that particular line.

Before we can expect to secure the best results from the money spent on our public roads, we must provide an efficient engineering organization to work with our board of supervisors. We must give our county supervisors the assistance of the technical training and years' of experience which go to make a finished road engineer.

Fig. 4.—Not the Result of a Flood but Lack of Proper Pile Driving.

The legislature recognized this fact when, in 1910, it passed the bill creating the present State Highway Commission. The appropriation for carrying on the work was, however, pitiably small, and although increases in the appropriation have been made from time to time, yet the demands for assistance from the commission have increased at a much faster rate than have the appropriations, and the commission is at present unable to carry on the work properly on account of a lack of funds.

One of the most difficult parts of the work of the commission has been to get the bridge and road work constructed in the field exactly as shown on the plans. In the majority of cases the work has been constructed without any adequate inspection or engineering supervision in the field. At times, carefully prepared plans have been practically ignored, and in one instance a very inferior arch bridge was built from carefully prepared plans for a flat-top bridge.

To properly handle the work and prevent such miscarriage of plans as shown above, each county should employ a highway engineer whose duties would be:—

To survey the roads and prepare profiles and estimates giving proper attention to drainage, traffic, surfacing, etc.

To relocate roads so as to avoid expensive bridges and excessive cuts and fills.

To prepare detailed plans, specifications and estimates for each bridge built.

To survey the drainage areas and plan the bridges with due consideration to the waterway required.

To inspect the work frequently and see that it is done according to the plans and specifications.

To keep a complete and accurate record of the amount and locations of the work done.

Such an engineer working in connection with the State Highway Commission would complete the organization and would render invaluable service to the cause of "good roads."

DISTRIBUTING SYSTEM OF NEW YORK'S WATER SUPPLY.

The waters of the new aqueduct which is being constructed from the Catskill Mountains to New York, will empty into the Hill View Reservoir before their final plunge into the heart of the city.

The problem of admitting so large a flood into the metropolis is no small one, particularly when the chief demand for the water will come from those sections of Greater New York which lie many miles away. For the present, at least, little if any of the Catskill water will be used in Manhattan and the Bronx, but most of it will be consumed by the boroughs of Brooklyn, Queens, and Richmond. The water waste campaign which has been carried on for the past few years has so far reduced the consumption of water that the Croton system, which can furnish steadily 350,000,000 gallons of water per day, can easily take care of the immediate wants of Manhattan and the Bronx as well as the demand from these two boroughs for many years to come. It is not likely that the population in Manhattan will increase much unless it undergoes a marked vertical growth, for now there are practically no more vacant lots to be built upon. So that in estimating the future demands upon the Croton system we must consider chiefly the growth of population in the Bronx. In the other three boroughs of the city, however, there is a present demand for water and the probability of large increases in population in coming years.

To conduct the Catskill water into Brooklyn and Queens, it was decided to build a trunk line, so far beneath the surface that there would always be 150 feet of good solid rock for the roof of the tunnel, and provide a course for a subterranean river which could be tapped as needed for the city's supply, and which, at the same time, would be so completely buried that it would never menace the safety of structures above it. When this tunnel is completed it will be one of the most durable pieces of work ever constructed by man; for practically nothing but an earthquake can destroy it; and even this possibility is very remote, for the rock underlying New York is of very early formation and not at all liable to seismic disturbance. And so the city tunnel of the Catskill aqueduct is being bored through the rock on the average of 200 to 250 feet below the surface except in places where the nature of the rock is of such a character as to call for a much greater depth.

The first dip takes place just above the Harlem River, where the tunnel drops down 362 feet below the ground level. Then it runs practically horizontally until it passes the dip in the rock under 125th Street. Thence it rises again and maintains a practically constant level of 200 feet under the city, until it arrives at the ancient bed of the East River. A glance at the map of New York city will show that the East River makes a decided turn about the lower east side or "heel" of Manhattan. In pre-glacial times, the East River had no elbow in its course, but ran directly across the heel of Manhattan, and it wore away the rock in its bed to considerable depths. However, the large deposits of earth

and rock carried by the glaciers caused the river to be pushed eastward out of its normal channel and over the solid rock beyond. When borings were made for the aqueduct through this section of the city, it was found necessary to lay it at a depth of about 750 feet below the surface. Much of the rock through this section is decayed and unfit to form the walls of a high-pressure aqueduct which is being built to last for all time. The present channel of the East River, on the other hand, passes over solid rock, and is comparatively very shallow. Seven hundred and fifty feet is an enormous depth, second only to the great siphon under the Hudson River, which is 1,114 feet below the river surface. It so happens that the deepest shaft ever sunk in New York city equals the height of the tallest building in the world.

Arrived in Brooklyn, the aqueduct rises again to within two or three hundred feet of the surface, and is pushed as far as it is possible to carry it in solid rock and yet communicate with the surface. This limit was found to be at the junction of Flatbush and Third Avenues. Here it was necessary to go through 215 feet of overlying earth before coming to the rock. The caisson method had to be resorted to and the caisson was sunk over 100 feet below the water line before rock was reached. Considerable difficulty was here experienced in sinking the shaft to the rock, because it called for the use of pneumatic pressure that taxed the endurance of the workmen to the limit. From here on the water will be conducted through pipes laid in a trench of a moderate depth below the surface. From the foot of Seventy-ninth Street, Bay Ridge, the conduit will be run across the Narrows to Staten Island, through a pipe 36 inches in diameter, provided with flexible joints, and laid in a submarine trench. The details of this section of the work have not yet been given out. However, tests have been made to discover at what depth the pipe line under the water must be buried. It is evident that it must lie far enough below ground to prevent its being entangled with anchors from large vessels that may have to anchor in the Narrows. The matter has been thoroughly investigated, and practical tests have been made by dragging anchors of large size along the bottom. It has been determined that if the pipe line is buried at least eight feet under the bed, it will be entirely safe. On the Staten Island side a 48-inch pipe will carry the water on up the hill and through a tunnel into Silver Lake reservoir, 120 miles from the source in the Catskills.

The greatest interest in this city section of the aqueduct attaches naturally to that part which is being excavated through solid rock under the busy city. It is a surprising fact that a work of such magnitude can be carried on directly under our feet without inconveniencing us in the least. The only surface evidence of the deep rock tunneling is to be found at the various shafts which are located in parks, or public squares. The principal difficulty that presented itself at first was the question of storing explosives for a work of such great proportion. To keep the necessary explosives on the surface was to harbor constant menaces to the lives of the citizens. The matter was finally solved by placing the dynamite magazines far under the surface in the rock, and setting the doors to these magazines so they will automatically close in case of an explosion and trap the hot and poisonous fumes in the rock chamber, where they can do no harm to the workmen. The idea was borrowed from European practice, where mining operations are conducted close to and sometimes directly under large cities. Access to the dynamite chamber is had through a zigzag drift. At each turn of the drift a pocket is excavated, and the chamber itself is made of large capacity. In this chamber the dynamite is stored under a protecting roof to keep off any fragments of rocks that might fall when jarred by the "shooting" in the tunnel. At the entrance of the [illegible] a very substantial concrete bulkhead is built, and in [illegible] a low doorway. The door is of massive construction, built of I-beams, sixteen inches deep and spaced apart with oak beams twelve inches square. The door has beveled edges, so that it will seat itself snugly in the doorway. The door is always kept open at an angle of about 45 degrees. In the magazine a thousand pounds of dynamite may be kept at a time. Should this be exploded, the explosion wave would have to travel down the zigzag passage and would lose much of its force at each abrupt turn, finally striking the door with greatly diminished energy. The door would be slammed shut by the blast of air issuing from the drift and would then be held shut by the gases of the exploded dynamite. A magazine of this sort has been constructed near the foot of each shaft—not at the foot, however, for fear that in case of a mishap, it might block the escape of the men. The magazines have been tested by exploding a number of sticks of dynamite around the first bend in the drift, and in every case the door has closed just as expected.

The work through the rock is being pushed very rapidly; at some of the shafts between 800 and 1,000 pounds of dynamite have been used daily. Within the last year millions of pounds of dynamite have been exploded under the city, while most of New York was totally oblivious to the fact. Already a number of the tunnel sections have been "holed" through. To expedite the work, one contractor is using an interesting form of shoveling machine, built especially for this work, so that it may be taken down the comparatively narrow shaft and be assembled to work within the small diameter of eleven feet, which is the size of the tunnel at the particular point where this machine is now being used. The machine is controlled by a single operator, and does the work of six laborers.

Some of the work on the city pressure tunnel has been hurried so far that certain sections are now being lined with concrete. The forms used for this purpose are very interesting. They cover 120 feet altogether and are arranged in two sections, sixty feet of the lower half of the tunnel being concreted in an advance of sixty feet of the upper part. The first step is to lay the "invert," that is, a narrow segment of the lining running along the bottom of the tunnel. This, when completed, forms the track upon which the forms for the rest of the lining travel. The forms are mounted on trucks with wheels tapered to fit the curve of the invert. The forms for the lower half cylinder are practically the same as those for the upper half cylinder. After the lining has set, the sides of the upper form may be drawn in to free them from the concrete, by operating the turnbuckles A, and those of the lower forms by operating the turnbuckle B. Then jacks may be unscrewed to lower the upper section slightly freeing it completely from the concrete and jacks E may be screwed up to raise the bottom section slightly upon the truck. In this collapsed condition the forms may be drawn forward to complete the next section of tunnel. It is quite a different task, however, to lay the concrete into the upper form. Sections of the plating of the upper forms are removed and the concrete is shoveled in, adding the plates step by step as necessary, until finally the topmost plate is added when the concrete can be introduced only from the end of the form. It will be observed that small pieces of board are temporarily nailed against the edge of the forms and fitted up as neatly as possible against the rock above, so as to retain the concrete until it sets. As each section is completed, grouting holes are left in the top through which, when the lining is completed otherwise, grout will be forced under high pressure to fill up all cracks and crevices and make the lining perfectly sound.

At each shaft access will be had to the tunnel through risers or vertical pipes, 48 or 72 inches in diameter. At most of the shafts two such pipes will be provided, each fitted with valves at the bottom which may be operated from the surface to close either of them when it is desired to gain access to them or to effect any necessary repairs. The valves at the bottom of the risers will be of such a design as to close automatically in case of an abnormal flow through the risers, due to the destruction of the valve at the top by explosion or other accident. At the top of the risers there will be two valves, the one nearer the riser being an emergency valve, which may be closed in case of any damage to the other valve.

It is probable that no immediate changes will be made in the water supply of Manhattan and Bronx, except that pipe lines will be run from the shafts to help out the existing supply in case of emergency. In Brooklyn and Queens, where thirty-five pumping stations are now required, most of the stations will be discontinued for the reason that the water will be delivered through the aqueduct at sufficient pressure to reach all parts. Only in one or two sections will pumping be necessary.

From Hill View reservoir the water will flow through a tunnel, 15 feet in diameter. This will be narrowed to 14, 13, 12 and 11 feet; which is the diameter of the rock tunnel at Fort Green Park, Brooklyn, and at the intersection of Flatbush and Third Avenues. From there on steel pipes, five and one-half feet in diameter and running down to four feet in diameter, will carry the water to the Narrows, and under New York Bay, at the Narrows, the line will be only three feet in diameter. This gradual shrinking of the aqueduct reminds one of those large rivers that flow out of the mountains in sufficient volume to be navigable and even a menace to the surrounding country in time of flood, but which, when they reach the deserts are drunk up by the thirsty sands and sucked by the torrid sun until they vanish without any clearly defined terminus or possibly flow in a sickly stream to a small stagnant lagoon. Thus, when the entire Catskill system is completed and operating at its full capacity, the waters which three days before poured out of the Ashokan reservoir in a mighty flood, over seventeen feet in diameter, will reach Staten Island, a stream only 3 per cent. of its former size, after having been robbed by the rest of the thirsty city.

LIMITATIONS OF BITUMINOUS CARPET SURFACES.*

By A. W. Dean, M. Am. Soc. C. E.†

A bituminous carpet surface is well defined as "a bituminous surface of appreciable thickness formed on top of a road crust by the application of one or more coats of bituminous material, with gravel, sand or stone chips added." Such a carpet is not formed by the use of oil emulsions, consequently, emulsions will not be considered in this discussion, nor will a crust approximating two inches in thickness be considered, inasmuch as when a coat or blanket is made of such thickness, it ceases to become a carpet, but rather becomes an integral part of the road crust or pavement.

Limitations in the use of bituminous carpet surfaces are governed by three principal features. First, character of the road crust under the carpet. Second, character of the carpet itself, including both the bitumen and the grit or such material as is applied with the bitumen. Third, character of traffic to be sustained. Taking these in their order named, let us first consider the character of the crust.

This should be of such a nature and on such foundation that the weight of the traffic will be thoroughly sustained without any aid whatever from the carpet. For average traffic on suburban roads, a water bound macadam road on a suitable and sufficient foundation is an ideal crust upon which to apply a bituminous carpet, regardless of the nature of the bitumen used to form the carpet. Under some conditions, a cement concrete crust is excellent and preferable to water bound macadam, in that it has more stability and will withstand a greater load. A concrete crust, however, does not appear to hold a carpet of an asphaltic nature as well as it holds one formed by the use of tar, the adhesion being apparently less with the former than with the latter material. A crust of good gravel, thoroughly compacted, is good under restricted traffic conditions, but it does not appear to hold a carpet formed by the use of heavy asphaltic or tar binders, unless the carpet is made of such thickness that it becomes a part of the road crust. Heavy binders as referred to herein are intended to mean binders that require heating to a temperature of at least 180 deg. F. in order to permit satisfactory application. A bituminous carpet on a gravel road appears to be successful under comparatively light traffic if a bitumen is used that does not require heating to a temperature above 100 deg. F. before application.

A carpet formed by the use of any material on a dirt road is of no value whatever, as it breaks up under any kind of traffic and very soon ceases to be a carpet.

Continuing to the second principal feature, namely, the character of the bituminous carpet, we have again a very important factor. The kind of bitumen used and the method under which it is applied, the kind and amount of grit used, and the character of the grit, each and all have a very decided influence on the limitations of economical use. Experience has shown that a carpet must be uniform in thickness, and in order to be so the bitumen and grit must each be spread uniformly, and in order to spread the bitumen uniformly experience has shown that it must be distributed by means of pressure applied in some manner, either by introducing air or steam pressure directly into the tank in which the bitumen is contained, or in securing pressure by means of a pump of some form. Experience has demonstrated also that where it is desired to make a carpet requiring the bitumen to be applied at the rate of ½ gal. per sq. yd., uniformity is more successfully obtained by applying the bitumen in successive layers of approximately ¼ gal. per sq. yd., each layer of bitumen being covered with grit before the succeeding layer is applied.

The grit used for covering the bitumen should contain no clay or loam, and if the traffic to be borne is a mixed traffic, with steel tires predominating, it appears that the best and most lasting results are obtained by using a mixture of coarse and fine material, the coarse material consisting of tough pebbles, or stone broken to pebble size (approximately ½ in. in diameter), mixed with material of a finer nature, such as sand or a coarse grade of stone dust. Such mixing is better accomplished if the two grades of grit are applied separately in forming the blanket, that is, the coarser material being applied first and immediately followed by the finer material. Such method of application appears to give a firmer carpet that will withstand a greater amount of steel tire traffic than will a carpet formed by the use of either coarse or fine material alone. If a car-

*Paper presented before the American Association for the advancement of Science, Cleveland, Ohio.

†Chief Engineer, Massachusetts Highway Commission.

pet is to carry a traffic consisting largely of automobiles, the coarser material does not become as necessary, although it appears to be preferable.

The kind of bituminous material that it is preferable to use in a carpet is still a debatable subject, particularly as to whether tar or asphalt products are preferable, and in the use of asphalts, whether a heavy asphalt requiring high temperature (200 deg. F. or more) before application is preferable to one that does not require such high temperature. It has been the experience and observation of the writer, however, that the asphalts requiring high temperature before application give better and more permanent results under a mixed traffic than do the lighter asphalts. By mixed traffic, the writer means a combination of trucks, automobiles and heavy and light horse-drawn vehicles. A carpet formed with a heavy asphaltic material, however, does not withstand traffic consisting largely of heavy steel tired vehicles, the effect of such being to cut the blanket and cause it to crumble and to soon disappear from the surface.

The third principal feature, namely, the character of traffic, must necessarily be considered in connection with the second principal feature, already discussed. In fact, neither one of these three features hereinbefore mentiond can be discussed entirely by itself, as each is dependent somewhat upon the others. With a suitable road crust to sustain a bituminous carpet, traffic is an extremely important factor in determining what type of materials to use for such a carpet. The amount, type and weight of vehicles must necessarily be considered. It has been demonstrated that a tar carpet will carry economically 100 automobiles per day per foot in width of roadway, together with a horse-drawn traffic of 15 vehicles per day per foot in width of roadway. On the other hand, a similar tar carpet failed under a traffic consisting of 20 heavy, horse-drawn, steel tired vehicles per foot in width of roadway per day, with only 8 automobiles per foot. This clearly demonstrates that a tar blanket is not suitable and should never be used to sustain heavy horse-drawn traffic, but is suitable and economical in carrying automobile traffic. Inasmuch as no particular wear appeared to be caused by the above mentioned automobile traffic, it is safe to assume that a much larger traffic could be economically carried. Records kept by the writer show that what has been stated above regarding the tar carpet is true also of the heavy asphaltic oil carpet. Failures that have occurred under the writer's observation with a heavy asphaltic oil carpet have occurred where the ratio of the number of automobiles to the number of horse-drawn vehicles was not any greater than two to one, and if the horse-drawn vehicles are of the heavy two-horse type, with narrow tyres, no amount of automobile traffic appears to be sufficient to counterbalance the destructive effect of 15 heavy horse-drawn vehicles per foot in width per day.

The writer is of the opinion that it is not wise at the present time to state general positive conclusions regarding limitations in the use of bituminous carpet surfaces. Such surfaces have been in use in this country only about four years, and the character and quality of the bitumen used at various times and in various places are so unequal, and the character of traffic over the highways is and has been changing so rapidly, that the results of experiments and observations have been variable. Positive and definite conclusions as to limitations can be drawn only after careful observation through a period of years, keeping a record of the kind and quality and amounts of material used in the carpet, and of the kinds, number and approximate weights of vehicles passing over the sections under observation.

THE ELECTRIFICATION OF TUNNELS.

With the announcement of the construction of several large tunnels by the different steam railways in the West, and the general electrification of tunnels in New York, etc., it is perhaps not out of place to recall and briefly describe the one large tunnel in use in Canada which, originally built for steam-operated trains, was electrolized and so operated in 1908, and has continued to give splendid satisfaction as such ever since.

The St. Clair tunnel under the St. Clair River, and connecting Sarnia, Ont., Canada, with Port Huron, Mich., United States of America, is more than two miles in length, including its approaches. The length of the tunnel proper is 6,025 feet, and the length of electric trackage, including yards, is approximately 12 miles. The tunnel has a maximum grade of two per cent., and was built under the St. Clair River by the Grand Trunk Railway under the supervision of Mr. Joseph Hobson, the chief engineer; Mr. T. E. Hillman, first assistant engineer, and Mr. M. S. Blacklock, second assistant engineer. It was constructed in order to overcome the obstacles presented by a navigable stream, alive with commerce during the summer, and often blocked by ice in winter, and previous to its opening the Grand Trunk Railway freighted the trains across the river by means of car-ferries. The tunnel is a continuous iron tube, nineteen feet ten inches in diameter, the total weight of iron being 56,000,000 pounds. Work was commenced in 1888, and the tunnel was opened for freight traffic in October, 1891, and passenger traffic in December of the same year. The cost was $2,700,000.

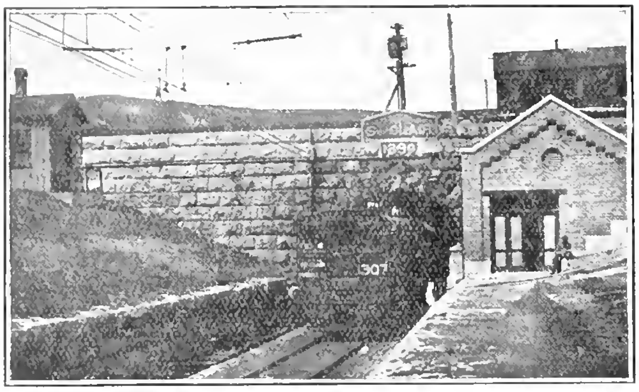
Western Portal of Tunnel.

Shortly after the opening of the tunnel for freight traffic the need of some method of doing away with the noxious and injurious gases, which formed from the smoke of the steam engines, was at once obvious. The natural remedy was the use of electric locomotives, and after mature deliberation, the Grand Trunk decided in favor of operating the tunnel by electricity. The power plant was located on the Port Huron bank of the St. Clair River and the length of zone electrified was four miles. The single-phase system was adopted, and the single catenary supported by structural steel bridges was the structural method used; the normal voltage being 3,300 volts. The Westinghouse Company finished the contract in May, 1908, and the cost was $600,000.

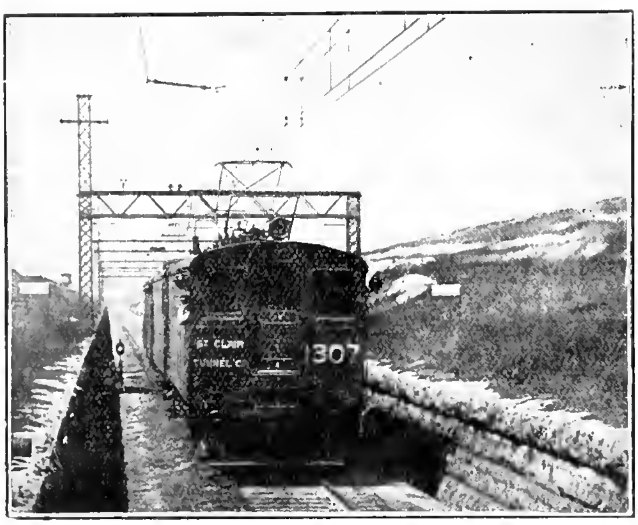
A comparison of the haulage before and after electrification is also interesting. The normal weight of trains hauled through the tunnel before electrification was 760 tons; after electrification it was 1,500 tons. The weight of the steam engines formerly used, which, when built, were the largest

in the world, was 200,000 pounds; the weight of the two electrical engines in use is 270,000 pounds each. The electrical engines have a normal motor capacity of 1,500 horsepower and a normal draw-bar pull of 50,000 pounds. A maximum speed of 35 miles per hour, and a minimum speed of 10 miles an hour up a two per cent. grade with a 1,000-ton train.

The tunnel has been a paying proposition, as the train service now operated through the St. Clair tunnel is very heavy. It is now lighted throughout, and presents the appearance of a well-lighted street instead of a tunnel sunk underneath a river, where the annual tonnage of vessels passing through is about twice as great as that passing through the Suez Canal.



Entrance to Eastern Portal.



Approach Crade and Engine.

In comparing the tunnel before and after electrification, one soon arrives at the conclusion that the correct method of operating a tunnel of any length is by electricity, as the evil-smelling and damp tunnel of before cannot be compared with the well-lighted, dry, and novel appearing passageway which the St. Clair tunnel now presents.

It is expected that New York's state barge canal will be ready as a whole in 1915. Locks are being built for 3,000-ton barges. An important percentage of the state's population lives within twenty miles of the canal on either side, and the motor truck will give farmers and manufacturers easy access.

THE INTERNATIONAL WATERWAYS COMMISSION.

In regard to the work now being carried on by the International Water Commission, Mr. L. J. Burpea recently stated that three important questions were being investigated by the commission.

The first of these relates to the levels of the Lake of the Woods and its tributary waters. This to some may seem a comparatively small matter, but in reality it involves very large interests, as far apart as Winnipeg and Duluth. The investigation is the outcome of complaints as to damage to lands along these waterways by flooding. The farming communities would like the level of the lake lowered. On the other hand, navigation interests complain that the water in the lake and its connecting rivers is already too low for their purposes. There are the fishing and lumbering interests to be considered, and the very important interests of power development. To reach a decision which will be fair to all these interests, on both sides of the boundary, the commission cannot afford to act hastily, or without having the fullest possible information on the subject. It now has survey parties representing both countries, obtaining technical data upon which it may base its conclusions. It has already held hearings at International Falls and Warroad on the American, and at Kenora on the Canadian side, at which everyone interested in the question, from any point of view, was given full opportunity to present his views. With this evidence and the engineering data, the commission will be in a position to recommend to the Canadian and American governments a solution of what has become a very intricate and troublesome problem.

The second question that the commission is investigating, and in which connection it recently held a meeting in Detroit, is the building of a dam in the Detroit River, in connection with the Livingstone Channel. This dam is intended to be built partly in Canadian waters, and is designed to protect the interests of navigation. At the Detroit hearing, however, a considerable difference of opinion developed among engineers and shipmasters as to the advantages of the proposed work; the town of Amherstburg complained that it would injure their waterfront, and counsel on behalf of the Dominion Government argued that one of the principal objects of the dam (to raise the level of the water) would be nullified by the unauthorized diversion of water at Chicago for the drainage canal, that a simpler and cheaper remedy would be to prevent this diversion, and that it would be preferable to deal with the dam, not as an isolated work, but a part and parcel of a comprehensive scheme of development of all these international waters for the benefit of the people of both countries. On the other hand, the American interests urged the necessity of the dam to safeguard the enormous traffic up and down the Detroit River. Here, again, the commission has a difficult and intricate problem to solve, and one that must be approached with the utmost care and absolute impartiality. Incidentally the evidence brought out threw light upon the amazing development of the shipping industry on the Great Lakes, the tonnage on the Detroit River in 1912 reaching the tremendous total of 95,000,000 tons, or over four times the tonnage passing through the Suez Canal; and the value of these shipments aggregated $800,000,000.

The third question the commission is investigating on behalf of the two governments is the exceedingly important one of the pollution of boundary waters. If the commission never succeeded in accomplishing anything more than helping to safeguard Canadians and Americans living along the international boundary, it would more than justify its ex-

istence. In this great undertaking it has the hearty co-operation not only of the federal health authorities at Washington and Ottawa, but also of state and provincial boards of health on either side of the boundary. During the coming summer a thorough examination will be made by sanitary experts to ascertain the principal sources of pollution, and when this data has been collected and digested the commission will be in a position to consider the remedy or remedies best assigned to meet the situation.

In addition to these questions, referred to it by the two governments, the commission also has before it several applications involving the erection of dams and other works in boundary waters. In such questions as these, under the terms of the treaty, the decision of the commission is final. It is in effect an international court of appeal, or, as it has been described, a Hague Tribunal for America, to which everyone interested, either for or against, any project involving the use of boundary waters of navigation, power purposes, sanitary canals, or irrigation, may appeal with the assurance of a fair hearing and an impartial decision.

COAL MINE FATALITIES FOR 1912.

The coal mine accidents occuring in the United States during the year 1912 have been compiled by the United States Bureau of Mines, under the direction of Frederick W Horton.

Mr. Horton, in reviewing the year, says: "During the calendar year 1912 there were 2,360 men killed in and about the coal mines of the United States. Based on an output of 550,000,000 short tons of coal produced by 750,000 men, the death rate per 1,000 employed was 3.15, and the number of men killed for every 1,000,000 tons of coal mined was 4.29. The number of men killed was the least since 1906; the death rate per 1,000 employed was the smallest since 1899; the death rate per 1,000,000 tons of coal mined was the lowest, and the number of tons of coal produced in proportion to the number of men killed was the greatest on record. These facts offer indisputable evidence that conditions tending toward safety in coal mining are actually improving and that coal is now being mined with less danger to the miner than ever before. The general improvement in 1912, as compared with 1911, is shown by the following facts:

In 1912 the number of men killed in the coal mines of the United States was 359 less than in 1911—2,360 as compared with 2,719—a decrease of 13.2 per cent., and this in spite of the fact that there were more men employed in the mines and more coal mined than in any previous year.

The death rate per 1,000 men employed in 1912 was 3.15, as against 3.73 in the previous year, a decrease of 15.5 per cent.

During 1912 for every 1,000,000 tons of coal mined 4.29 men were killed, as compared with 5.48 men in 1911, a decrease of 21.7 per cent.

There was 233,000 tons of coal mined for each man killed in 1912, as compared with 183,000 tons in 1911, an increase of 50,000 tons, or 27.3 per cent.

Although the improvement in 1912 was greater than in any previous year for which accurate statistics are available, partly due, perhaps, to exceptionally mild weather during the last few months of the year decreasing the likelihood of disastrous coal-dust explosions, there has been an annual improvement for a number of years, as indicated by the accompanying table:—

Number of Men Killed in and About the Coal Mines of the United States in the Calendar Years 1907 to 1912, Inclusive, With Death Rates.

	— Number killed—			
Year.	Total.	Per 1,000 employed.	Per 1,000,000 short tons mined.	Production per death, short tons.
1907	3,197	4.88	6.93	144,000
1908	2,449	3.64	6.05	165,000
1909	2,668	4.00	5.79	173,000
1910	2,840	3.92	5.09	177,000
1911	2,719	3.73	5.48	183,000
1912	2,360	3.15	4.29	233,000

It will be noted from the foregoing table that the death rate per 1,000,000 tons of coal mined has decreased annually, that the production per death has increased each year since 1907, and that the death rate per 1,000 men employed has steadily decreased during the last four years.

This general improvement has been brought about by a combination of causes, the principal one of which has been more efficient and effective mine inspection on the part of the State mining departments and State mine inspectors throughout the country, supplemented by greater care on the part of both the operators and the miners. The investigative and educational work of the Bureau of Mines has kept the operator and the miner alive to the various dangers connected with coal mining and has shown what precautions should be taken to avoid these dangers. The bureau is, therefore, gratified with the improvement shown, particularly as the greatest improvement relates to dangers concerning which the bureau has been conducting special investigations, as is shown later. The bureau, however, can not too strongly express its appreciation of the co-operation of the State mining officials and the operators in the work of making coal mining safer.

Although there has been an annual improvement in mine-safety conditions since 1907, and a particularly notable one in 1912, a still greater decrease in the death rate can be effected. Whether or not such an improvement will be made in 1913 depends largely on the care exercised by the operators, superintendents foremen, and all others in authority, and by the miners as well, to prevent the rise of dangerous conditions and to avoid unnecessary risks when such conditions have arisen.

The R.M.S. "Kyle," which is being built and engined at the Neptune Works of Swan, Hunter and Wigham Richardson, Limited, to the order of the Reid Newfoundland Co., of St. John's, Newfoundland, was recently successfully launched. The steamer is intended for the mail and passenger service between Newfoundland and Labrador coast, and is exceptionally strongly constructed for running the ice which she will frequently meet on service. She is 220 ft. in length by 32 ft. beam and will be rigged as a two masted schooner. She is to be fitted with accommodation amidships for 68 first-class passengers, including dining saloon with seating accommodation for 32, ladies' room, smoking room, etc., and there will be a good promenade deck for the passengers' use. Aft there is to be accommodation for second class passengers, 102 men and 40 women, and there are two hospitals, one for men and one for women in a deckhouse above. There will be a complete installation of electric light, including searchlight, efficient arrangement of steam heating suitable for the climate, and wireless telegraphy will also be fitted. The steamer will be propelled by single screw triple expansion engines.

COAST TO COAST.

Toronto, Ont.—The Niagara park commission is completing arrangements for the granting of a concession to a Spanish company for the installing of an aerial tramway over the whirlpool. The tramway will be about a third of a mile long and will cross from one Canadian shore to the other, greatly lessening the distance which is now covered by the International Railway which runs around the whirlpool. The immensity of the undertaking may be appreciated when it is considered that the pool must be spanned by a single cable with no support beyond the towers and anchors at each end, and that at the same time this cable must be sufficiently strong to carry the cars and passengers.

Toronto, Ont.—John Gott, chief electrical engineer of the Commercial Cable Company, has invented a device by which the Morse dot and dash signals can be used on long submarine cables, and by which a message was sent recently from Toronto to London, Eng., direct without relaying; that is, the message was sent by the ordinary land line Morse key and read on a Morse sounder. Lord Kelvin invented the first instrument to decipher signals, and it was called the Thomson reflecting galvonometer, or what is commonly known as the "mirror." The great objection to the "mirror" was that no permanent record of the message was sent, the reader calling off the message to an assistant as it was reflected. Sir William Thomson then invented the siphon recorder, which overcame the difficulty of not providing a record. In the siphon recorder a light coil of wire is suspended in the field of a powerful magnet, and the movements of the coil in response to the current through the cable are recorded on a narrow paper tape passed in front of a fine glass siphon attached by silk fibres to the suspended coil and dipping into an ink-well. The end of the siphon traces in ink a line on the tape, and this line goes up and down in response to the movements of the coil from side to side in response to a change in the polarity of the current. When a point of the line rises up above a fixed point it means a dot and a valley is a dash. Only practice can enable a man to read accurately and quickly a message by the siphon record. The technical details of the Gott invention are not being told at present, but the same voltage as at present used is required, and it is said that very little new machinery is needed. One feature of the Gott system is a delicate instrument which magnifies the faint note of the far-travelling dot and dash, and increases the volume of sound into a loud click. It is quite probable in the opinion of electricians that by Mr. Gott's invention it will be possible to transmit through automatic repeaters telegraph signals around the world, and the time will be less than one second.

Victoria, B.C.—A publication of the Pacific Highway Association of North America records the creation in Oregon of a State Highway Department, whose engineer will be at the service of all county courts that may desire advice and assistance from him. A strong point is made that all money raised by bonds for road purposes must be spent along permanent lines. Statistics are given showing amounts of money expended on roads in Oregon for the last four years and the number of miles of $5,000 per mile road could have been built for the same amount. The cost of the Pacific Highway through Cowlitz county is shown at $8,542.73 for grading and bridging per mile. The concluding paragraph of the bulletin runs: "The problems for the Pacific Highway Association to solve during the next two years are many. Among the most important is the erection of the Pacific Highway sign from Redding, California, to San Diego. In Oregon and Washington the problem is to encourage the local authorities to put the Pacific Highway in as good condition as possible before the Panama Exposition in 1915. The construction of the highway in California will be taken care of by the state. During the next two years, one, and probably two, hard surfaced roads will be completed throughout that state from north to south. In British Columbia the highway will be completed by the provincial government by 1915. This year British Columbia will spend approximately $6,000,000 on roads.

Saskatoon, Sask.—The subject of an interprovincial highway across Canada is on the programme of the Union of Canadian Municipalities for its next convention at Saskatoon. In order that the enterprise may be brought with united force to the attention of the Dominion and provincial governments, municipal councils are now being asked to adopt the following form of resolutiou: "Resolved, that this council is strongly in favor of the making by, or in conjunction with, the governments concerned, an interprovincial highway, of good standard construction, across Canada. This council request the Union of Canadian Municipalities to secure united action for the purpose."

Victoria, B.C.—Following the custom of previous years, the health authorities of this city soon will start another campaign against insanitary structures and the conditions which make them a menace to the public from the viewpoint of health and fire. For some time past the sanitary inspector has been making a tour of the city with a view of listing all those premises which, in his opinion, should be demolished, and at an early session of the city council authority to start condemnation proceedings against such buildings will be sought. There are at present on the list approximately fifty buildings and sheds which come within the list of dangerous premises. A great number of these are stables in the outlying sections, the condition of which cannot be improved to meet the by-law requirements in the way of sewer connection and other sanitary arrangements. Within the past two years the policy of the city in ordering the destruction of sheds has been followed. In Chinatown the campaign was especially energetic, with the result that a great number of insanitary wooden outhouses, verandahs, fences, etc., were destroyed, and in consequence the sanitary conditions in that section materially improved. The medical health officer, Dr. G. A. B. Hall, Sanitary Inspector Lancaster, and Fire Chief Davis are the officials who are chiefly concerned in this work, and their joint report will soon be forthcoming.

Calgary, Alta.—Mr. R. A. Ross, at present acting general manager of the Toronto Hydro-Electric, in his recent report to the city on the power question, made the following recommendations: "For future extensions thereafter, if there is no change in the art in the next few years, steam turbines with gas-fired boilers will be our recommendation, in spite of the greater economy of the gas engine. Should the development of the gas engine or gas turbine or some other improvement render it possible to utilize other sources of power than that recommended there will be no difficulty in introducing it later when it is ripe. Our recommendations are as above in spite of the fact that the gas engine, from a power standpoint, is the cheapest. In combination with hydro power steam from gas-fired boilers is cheaper than hydro and gas engine up to 20,000 kilowats. The natural gas engine is hampered as follows: The great capital investment being 100 per cent. more than for steam equipment. The whole service will depend upon the integrity of a pipe line 172 miles long. The large gas engine is not in such a stage of development as yet as will insure its success in your plant, and the use of smaller units would increase the capital and operating costs considerably over those indicated

in our report. The advantages of steam as compared with gas in this case are as follows: The decreased capital cost involved. The utilization of natural gas with coal as a standby in case of failure of pipe line. The establishment of a plant in which every item has been tried out for years and in which no experimenting is necessary, and the greater probability of quick deliveries of apparatus."

Ottawa, Ont.—In regards the petitions that have been received from the landowners on a number of streets asking to have tarvia macadam streets constructed, Controller Nelson issued the following statement: "What we propose to do in these cases is to construct a more substantial roadway than the tarvia macadam as used on the Improvement Commission driveway. We propose to build up the streets of broken stone as in the case of the ordinary macadam road. Then have six inches of smaller broken stone mixed with tarvia and above this two inches of tarvia and very fine stone, covered with a layer of tarvia and dust. This, it is believed, will prove most satisfactory, making over eight inches of solid composition of broken stone and tarvia. The residents along Center Street who petitioned for an asphalt pavement last fall are now endeavoring to have it changed to this kind of roadway, which will be less expensive, not nearly as dusty, not so noisy, and does not require sprinkling. It is the intention of the works department to make several experiments in regard to the use of a simple top dressing of tarvia and dust along other streets. Last summer, on Mutchmore Street, west of Bank Street, we had the street swept and a thin coat of tarvia and dust put on. This was done only once, yet to-day, going along Mutchmore Street in this section, you will see the effect still remaining, and in places it is as smooth and hard as the top face of asphalt. We think that if this were done continuously for a number of years it would form a solid face on the street that would be as good as pavement. We are going to try it on Wurtemburg Street, from Rideau north to the end of the street; on McLeod, from Elgin to Bank Street, and on Fourth Avenue, west of Bank. This will be done out of general fund, less what will come out of the sprinkling that will be saved on these streets. The permanent tarvia macadam will be done under local improvement.

Regina, Sask.—Despite the general financial stringency, which is but slowly loosening up, building operations are in full swing in this city. The steel work has been completed now on the ten-story McCallum Hill building, and work is being rushed on putting on the tiling floors. The announcement has been made with respect to the change of plans of the Grand Trunk Pacific Railway. This company intended to erect a nine-story hotel at a cost of $1,000,000 and a two-story station. The hotel as originally designed will be erected. The station, however, will be much more elaborate. It will be a five-story structure, according to the official announcement, and it is now proposed to join the station and the hotel by means of a well-equipped underground passage. It is generally understood that the total cost will be well over $2,000,000. The Dominion Government has decided to dredge the Qu'Appelle River where it links up with the Fishing Lakes in the vicinity of Fort Qu'Appelle, and to construct three dams, which will considerably increase transportation facilities. The Provincial Government is draining the Wascana Lake in order to lay pipes for a reserve water supply for the Parliament buildings. Construction work on the street railway extensions has already been started, and at the present time there are about one hundred men at work, and in the course of the next month and a half it is expected that there will be at least four hundred employed. Altogether, $825,000 will be expended by the city on street railway work.

ELECTRIC DEVELOPMENT UNDER AN UNUSUAL HEAD OF WATER.

The Swiss, as a nation, are generally given credit for being the leaders in the design and manufacture of electric machinery designed for use under high heads of water. Word comes to hand of a power development scheme which outdoes, in the use of an available head of water of 5,412 feet, any previous development of which the writer is aware.

Mr. Boucher, of Lousanne, Switzerland, a civil engineer who has designed many other water power schemes with comparatively high heads, and who is a member of the board of the Society of the Electro Chimie, of Paris, has persuaded them to carry into execution the conversion of the water power of the Lake of Fully, near Martigny, in Canton Wallis, Switzerland, with a head of 5,412 feet, into electric energy. The execution of this project has been fully resolved upon, the work commenced, and the orders for the necessary materials placed.

The most interesting question in connection with this scheme arose when deciding in what manner the pipe line should be constructed in order to withstand a pressure of 2,425 lbs. per square inch at the lower end. However, a most satisfactory, as well as perfectly simple, solution was found.

The pipe line in a length of about 2¾ miles consists of pipes with inside diameters of 19 11/16 inches and 23⅝ inches, and thicknesses of from 15/64 inch to 1 25/32 inches. The pipes of the upper section will be of the well-known water gas lapwelded type, whereas those of the lower part will be seamless.

These seamless pipes, which are drawn in strong drawpresses from a steel ingot, and which can be made up to the largest diameters, offer as high a security as one could wish on account of their perfect homogeneity, especially for schemes of such high demands as the present.

The turbines for 15,000 horse-power will be built by the engineering firm of Piccard, Pictet & Company, Geneva. The construction of the pipe line is in the hands of Thyssen & Company, who possess at Muelheim-Ruhr extensive steel, plate, and tube works, as well as a water gas welding plant for large pipes, and where a great many pipe lines for water power plants have already been constructed.

PERSONAL.

MR. J. J. ANTONISEN, city engineer of Moose Jaw, Sask., has been appointed street railway commissioner at Brandon, Man. Mr. Antonisen is a graduate of Leipzig University and formerly divisional engineer for the Canadian Pacific Railway. Prior to going to Moose Jaw he was city engineer at Port Arthur, Ont.

MR. J. E. ASKWITH, assistant city engineer of Prince Albert, has been appointed first permanent town engineer of Redcliffe, Alta.

STANLEY H. FROME, resident engineer of the Grand Trunk Pacific Railway at Calgary, has been appointed to the staff of the city engineer of that city. Mr. Frome's work with the city will be connected with taking soundings and the construction of concrete bridges.

MR. W. W. BELL, until recently chief assistant to Major Hodgins for the construction work of the Grand Trunk Railway, has been appointed engineer for the construction of the Banff-Windmere Road.

OBITUARY.

MR. E. B. WINGATE, former city engineer of Hamilton, Ont., and one of the best known civil engineers in Canada, died recently at the age of 58 years. Deceased was a native of Philadelphia, Pa., where he received his education and was employed in the engineering department there. He planned the tunnel and bridge at the canal for the T. H. & B. Railway. He was shortly after appointed city engineer of Hamilton, from which position he resigned owing to ill-health caused by hardships suffered while engaged in railroad work in South America.

CANADIAN PUBLIC HEALTH ASSOCIATION CONGRESS.

The 3rd annual congress of the association will be held in Regina, Saskatchewan, September 18th, 19th and 20th. Local secretary, R. H. Murray, Bureau of Public Health, Regina.

Arrangements are now being made by a local committee and further information will be available in the course of a few weeks.

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, T. S. Young, 220 King Street W., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Mucklestone; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, P. Pardo Wilson. Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, P. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290. Meets 2nd Thursday in each month at Club Rooms, 584 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

An Engineering Weekly

FREIGHT TERMINALS AND FREIGHT HANDLING AT TERMINALS.

By J. S. BUSFIELD, B.Sc., A.C.G.I.*

The problem of designing a freight terminal and of handling the freight in the terminal is one that is becoming more and more complex, and in making a study of any one particular situation a great many controlling factors have to be taken into consideration. Difficulties are introduced owing to the requirements in one town or city being different from any other town or city, so that the company which wishes to design a terminal for a certain city has no terminal situated and operated under exactly similar conditions which it can copy, but must make an independent study of the local conditions and requirements and then gather together as much information as possible in connection with the design and operation of as many other terminals as possible. It is beyond the scope of this article to deal with a great many of the modern freight terminals, but an attempt will be made to give a general description of the requirements and the methods employed at some of the up-to-date terminals handling large quantities of L.C.L. freight.

The handling of package—L.C.L—freight at the terminal is the most expensive item in the cost of its transportation from one point to another, so that a freight terminal must be so designed as to permit of the most economical and efficient handling of freight from the wagons and drays to the freight cars, and vice-versa.

Under the economic conditions prevailing, wages are continually increasing and at the same time, it is commonly asserted, human efficiency for performing physical work is diminishing, consequently all commercial interests are working to eliminate the human element by introducing all kinds of mechanical labor-saving devices for performing the work formerly done by man, and in recent years great strides have been made in the use of machinery for handling package freight, for it has been estimated that the cost of handling a ton of freight at its starting point and destination is over 10 times the cost of transporting it 100 miles on the railway.

Location.—In making a study of the conditions controlling the design of a freight station the first thing to be taken into consideration is the location of the terminal, as this is one of the most important items which will determine whether the railway company will obtain a large share of the city's business or not. In a great many cases there is no choice, but where there is, great care should be taken to have the terminal in the centre of the shipping district—using the word shipping to include consignors and consignees—because, other conditions being equal, the shipper will send his consignments to the nearest freight house. The placing of the terminal in the heart of a business district naturally means very high prices for the necessary land, but this can often be compensated by the use of a freight house of two or more stories, in fact, this type of house is coming more and more into use, not only on account of land values, but more particularly on account of the railway tracks having to be either elevated or depressed from the natural ground surface in order to eliminate grade crossings in the busy parts of the town or city. Details of this type of house will be dealt with later.

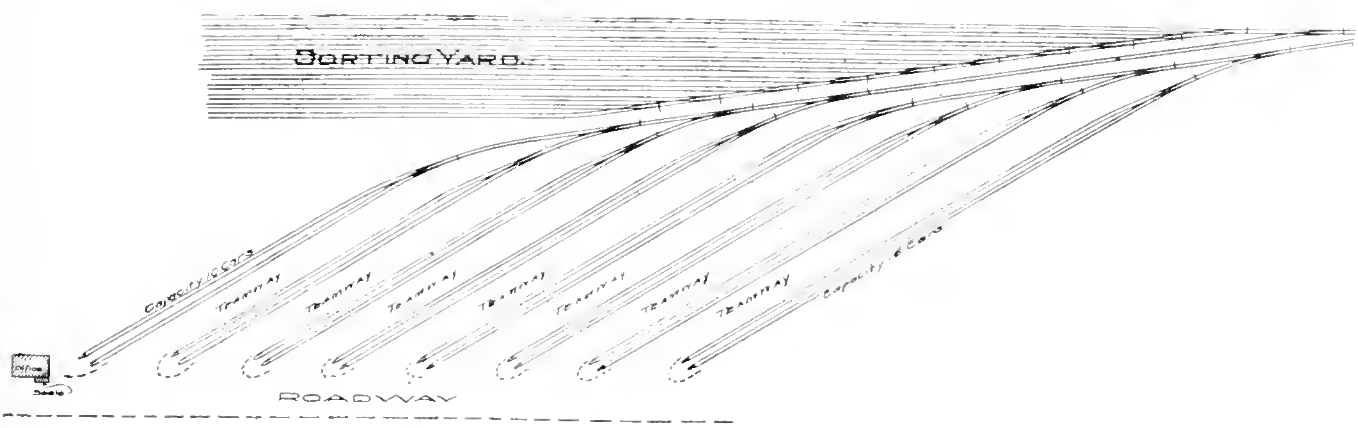

Fig. 1.—Typical Team Yard.

Layout.—Having selected the most suitable site for the freight house, and the necessary capacity decided upon, the next step is to look into the question of track layouts, storage and handling sheds and platforms, office, etc., and in doing this the capability of future extension must not be overlooked, as it is usually the best policy to acquire the necessary

* With the Montreal Tunnel and Terminal Company.

property at an early stage rather than wait until it has increased in value to prohibitive prices; and in this country of rapid growth future extensions of every kind of plant have to be properly provided for.

The general design of terminal sheds will be found to be different in almost every terminal examined, as they are always governed by such local conditions as the general topography of the surrounding neighborhood, the property limits, location of the streets in the immediate vicinity, direction of traffic, nature of the commodities to be handled, and numerous other factors.

surface or else with some standard paving block, care being taken to provide sufficient drainage facilities, as a muddy and heavy teamway is very detrimental to the business. Team tracks, as a general rule, should not be made excessively long, as this increases the cost of switching and making up the trains; the most convenient length has been found by experience to be about 400 to 600 feet in the clear, giving a car capacity of from 10 to 15 cars on each track.

For handling heavy machinery, boilers, lumber, etc., it is usual to provide one or more overhead travelling cranes. These are frequently made to span a teamway and the two

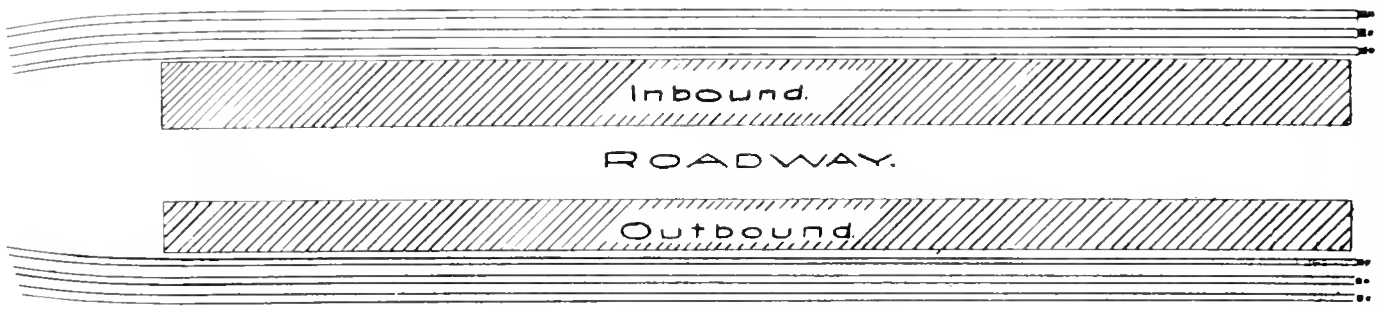

Fig. 2.—Typical Freight Shed Layout.

Mechanical Handling.—Mechanical handling of freight has not been adopted except in some of the most modern of large terminals, although various systems are being largely used at steamship piers where freight, both package and in bulk, has to be moved over longer distances and over more definite route than are obtainable in the average freight shed for handling freight from the cars to drays and storage spaces and vice versa. There are various systems, however, which are adaptable to the mixed requirements of the freight terminal, which will be described later.

Team Yards.—In addition to the freight sheds where L.C.L. freight is handled, a freight terminal is hardly complete without a team delivery yard for delivering car-load freight direct from the cars to the teams. A typical layout of a team yard is shown in Fig. 1, and this type of yard is

adjacent tracks, or the teamway and each pair of adjacent tracks, or the teamway and one pair of tracks. In fact there are numerous different ways of locating the crane which, again, may be fixed or travel on its own track in the same direction as the team tracks.

Freight Sheds.—The freight sheds most commonly encountered are those which are situated with the tracks and sheds on the same level as the roadways. In some of these one shed is used for both the inbound and outbound freight —it should perhaps be mentioned here that inbound freight refers to the freight brought in by the railway and outbound that taken out by the railway—but in other cases where a greater quantity of merchandise is handled the two sheds are kept separate, and although it is not done in every case it is distinctively advisable to have the inbound shed considerably

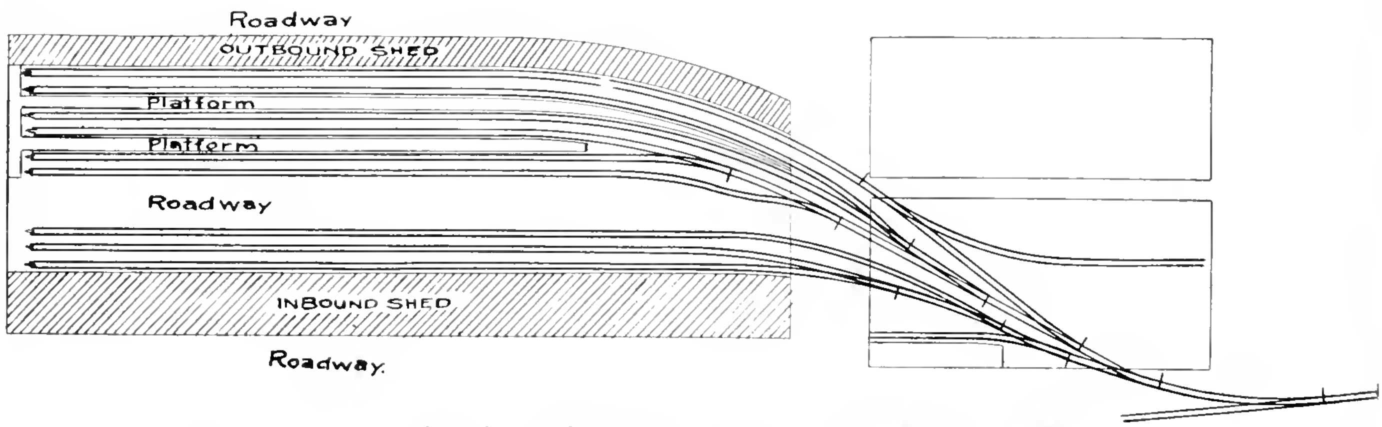

Fig. 4.—Freight Sheds and Transfer Platform, Rock Island Railway, St. Louis.

usually employed, modified in some form or other to suit the local conditions.

As will be seen in Fig. 1, the tracks are laid in pairs, with from 11 ft. 6 in. to 13 ft. centres between them. The width of the teamway is frequently made 40 ft. clear between the tracks, but in cases where a more economical layout is required and land is high priced, they can be narrowed down to 30 ft., but this latter is very apt to cause crowding and congestion, hence delays in the handling of the freight. The teamways should always be well made, either with a macadam

larger than the outbound because a fair percentage of the inbound freight has to be stored pending the arrival of the consignee's wagons to take it away, whereas in the outbound shed the merchandise deposited by the wagons can usually be taken direct to the cars. A certain quantity, however, has to be stored as frequently cars destined to certain points are only placed at the sheds on alternate days in order to insure a full load instead of shipping small loads, or having the goods transferred at some division point or transfer station.

There is a great deal of diversity of opinion with regard to the arrangement of tracks alongside the sheds, but the commonest method is to have two or three tracks on one side of the shed and have the cars spotted opposite the shed doors, with the doors of all three cars in line so that the outer one is loaded or unloaded through the other two. A general arrangement of this type of terminal is shown in Fig. 2.

This system has the great disadvantage of the costliness and danger of uncoupling, spotting and recoupling all the cars, and also of the congestion liable to happen on account of three cars all having to be worked through the one opening, but with this type of shed there is no immediate remedy, and it has its advantages which in many cases counteract the disadvantages.

Another type of freight house, differing somewhat from the general run, is that erected by the Pennsylvania Railroad at Indianapolis. (Illustrated in Fig. 3). The shed itself is L-shaped with the two portions 50 ft. x 335 ft. and 40 ft. x 180 ft. respectively. The tracks are spaced with 11 feet centres, and the intermediate platforms are 12 feet wide.

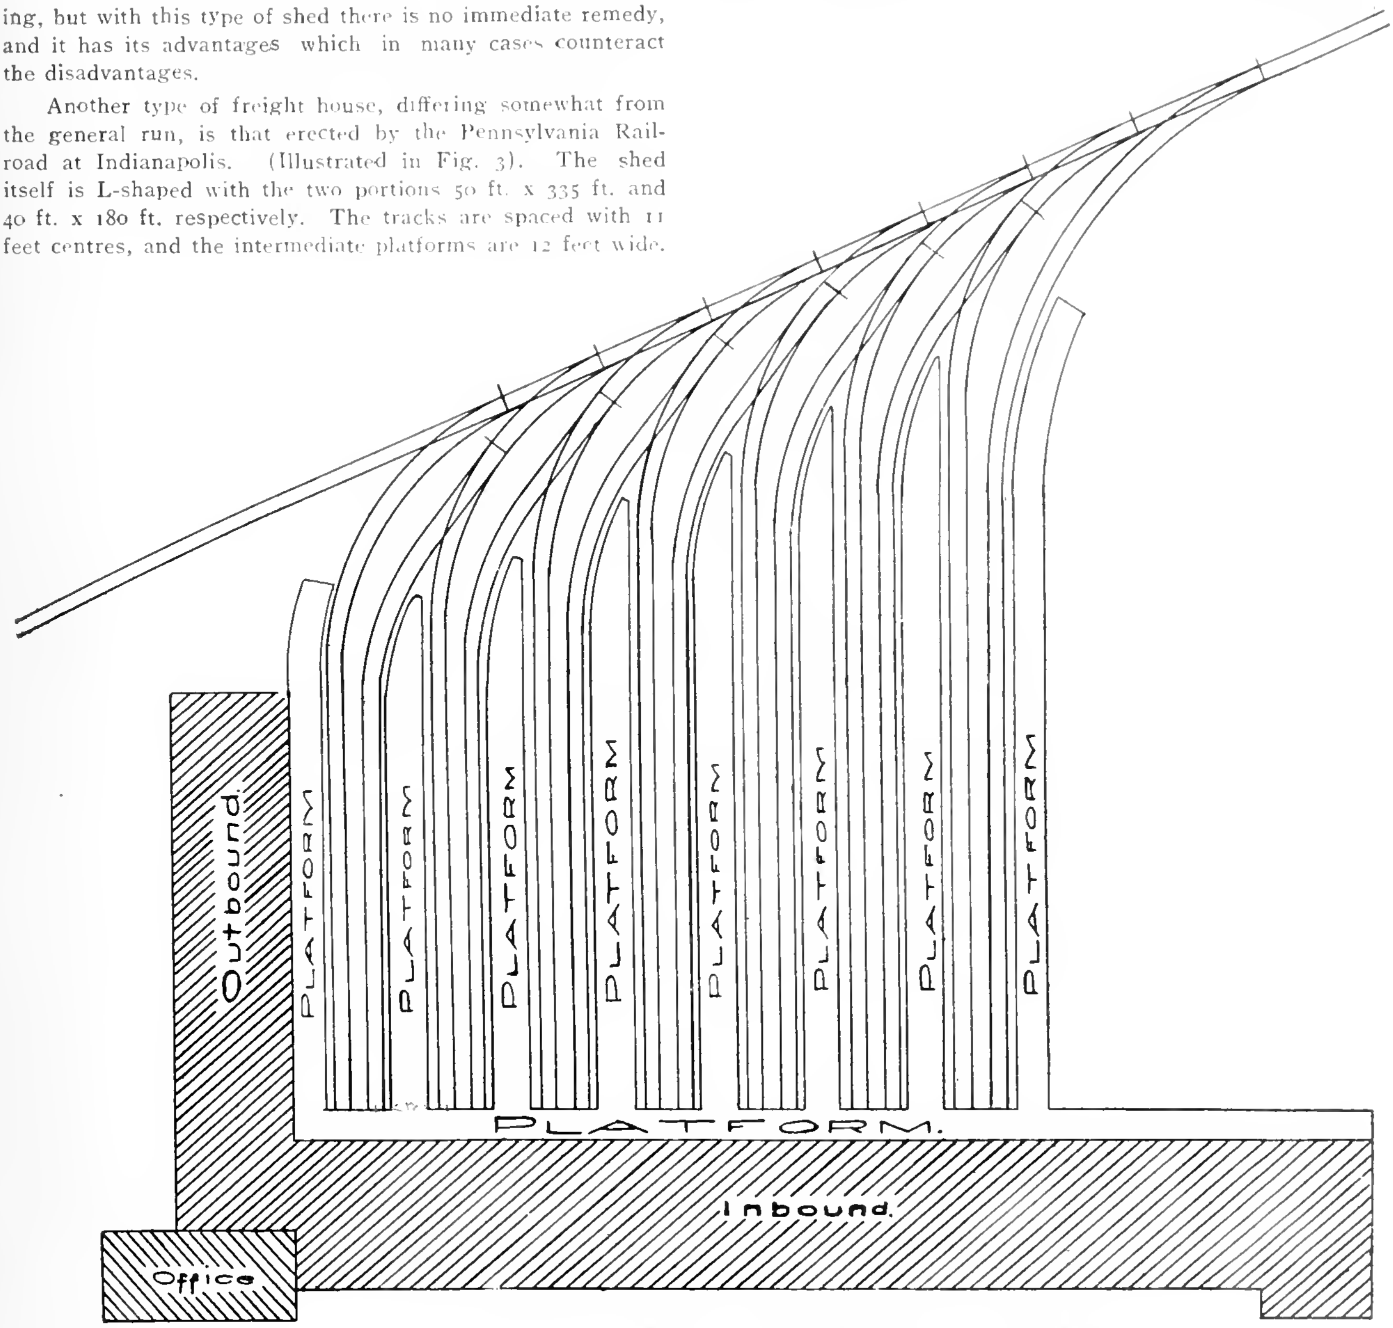

Fig. 3.—Freight Shed of Pennsylvania Railway at Indianapolis.

On account of the limits of the property the tracks are laid with curves of 100 feet radius.

Still another type of modern freight terminal is that of the Rock Island in St. Louis. A plan of this is shown in Fig. 4. The outbound house is 24 ft. x 570 ft. and the inbound house 46 ft. x 577 ft. and two 8-ft. transfer platforms are provided.

Figure 5 illustrates the freight terminal built by the Lake Shore Railway at Toledo, Ohio, and at first sight it does not look as though it could be operated very efficiently on account of the great amount of trucking required, but contrary to expectations the claim is made that the freight handled at a cost of about 35 cents per ton.

From these few examples of terminals illustrated will be seen that in general terminals on the one level may be divided into two classes, namely, those in which the in and outbound freight can be handled to and from the cars without having to switch the cars from one track to another and, second, those in which the cars, after being unloaded at the inbound shed, have to be switched to the outbound shed to be loaded. Now, as a general rule, it is fairly safe to say that it is more economical to move freight to the cars than it is to move cars to the freight, so that the former of the two classes presents the best features for economical operation, although in many cases the reduction in cost of switching is counterbalanced, or even overbalanced, by the additional

cost of handling the freight in the terminal due to the longer haul necessitated by this arrangement.

Two-Story Freight Houses.—The best way of handling freight in and outbound without having to switch the cars from one shed to another, or having a very long trucking haul is to adopt a two story freight house. This type has other good features, such as economy of land, and is readily adaptable to modern conditions which require the tracks to be elevated or depressed in order to eliminate grade crossings. It is roughly estimated that $2 per square foot will

for loading and unloading the freight from the cars. Five large high-power elevators are provided for handling the freight between the different stories.

Still another type is that of the Wisconsin Central in Minneapolis. This house is 417 feet long and varies from 66 feet 1 inch to 79 feet 7 inches wide. The tracks are below the street level, and all freight is handled on a 24-foot platform and outbound freight is brought in on a low level roadway direct to this platform, ten 6-ton scales being provided, one for each of the doorways. There are four 5-ton and one

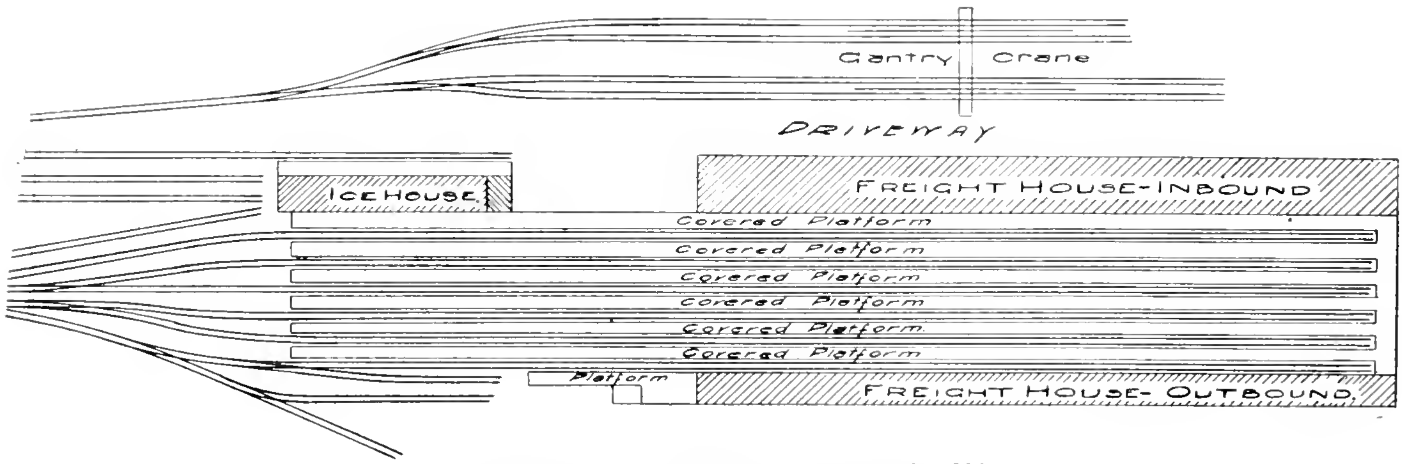

Fig. 5.—Freight Shed, Lake Shore Railway, Toledo, Ohio.

cover the additional cost of a two-story, slow-burning construction building, above the cost of a single-story building of similar construction.

A modern freight shed with four different floor levels is that of the Wabash Railroad at Pittsburgh, Pa, illustrated in Fig. 6. The tracks are on a high level, and the space between the unloading and loading platform and the teamways is occupied with storage rooms. The total width of the house is 145 feet and the length 572 feet, and it has accommodation for 50 cars, or, including storage space, 125 cars.

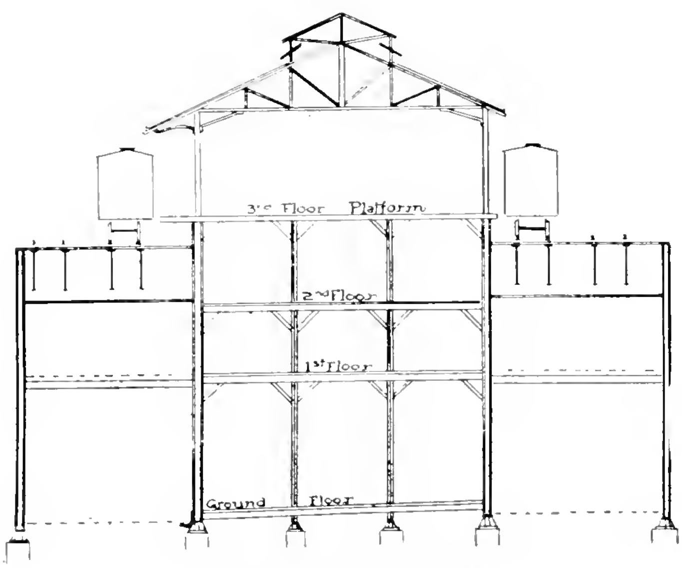

Fig. 6.—Cross Section Wabash Freight Terminal, Pittsburgh, Pa.

The ground floor is used for delivering and receiving freight and is paved with asphalt. The first and second floors are used for storage and are divided up into a number of warerooms, which are rented for the convenience of shippers. The third floor is that upon which is situated the platform

10-ton elevators for taking the inbound freight up to the street level, where it is stored or delivered to the teams. There are also two additional storage floors above this, the total storage area being 100,000 square feet.

In both these sheds the handling of the freight between the cars and teams and storage rooms is done entirely by hand trucking, but there are a number of sheds in which the freight is entirely handled by mechanical means, which will be described in connection with the mechanical handling plants.

Mechanical Handling of Freight.—At the present day there are very few plants in operation for the transference and general handling of package freight at terminals where large quantities of package freight are handled between cars and drays, but a great deal of attention has been paid to the subject within recent years, and there are quite a number of different methods from which one, or a combination of two or more, of these methods may be selected to meet the special requirements of any particular case. Quite a number of plants of different kinds have been installed at steamship piers and freight transfer stations and warehouses, but the conditions to be dealt with are usually quite different in these cases to those obtained at freight terminals for handling L.C.L. freight.

Now, before the subject can be dealt with in an intelligent way, the requirements, method of operating and all the local conditions have to be thoroughly understood. The old method of handling freight at the sheds required six operations for outbound freight and two to three for inbound, as follows:—

Outbound Freight.

(1) Checking and receipting freight at platform.
(2) Designating packages for proper cars.
(3) Moving the hand trucks to scales by one gang.
(4) Weighing.
(5) Trucking from scales to cars by another gang.
(6) Stowing in cars by third gang.

Inbound Freight.

(a)

(1) Unloading from cars.
(2) Trucking to wagons.

(b)

(1) Unloading from cars.
(2) Trucking to storage space.
(3) Trucking from storage to wagons.

In order to increase the efficiency of the working of the terminal and hence reduce the cost per ton of merchandise handled in the terminal, a mechanical freight handling plant must conform as closely as possible to the following requirements:—

(1) It must eliminate rehandling as much as possible.
(2) It must cause no congestion.
(3) It should be so designed and operated as to give a large increased capacity to the terminal compared with the old hand trucking method.
(4) The operating expenses should be reduced.
(5) The switching of cars should be reduced as much as possible.

A type of moving platform has been devised for handling freight, and is capable of development for use in a variety of cases. This platform can be used either to carry the package placed directly on the conveyer or else to move the trucks in which the freight is loaded. For use in a large freight shed two of these platforms could be placed on either side of the shed, moving in opposite directions. A great many suggestions have been made with regard to the use of these platforms, but they do not seem to have been used to any very great extent.

Some are in favor of a moving platform three to four inches above the level of the stationary platform, with short ramps, adjacent to it, while others think that the platform should be set in level with the shed floor. The relative value of these methods will probably only be settled by experience.

Another type, similar in operation to the moving platform, but different in construction, is the chain conveyer, different views of which are shown in Fig. 7. As will be seen, this is simply another means of moving the ordinary hand trucks at a fair rate of speed along fixed lines. The

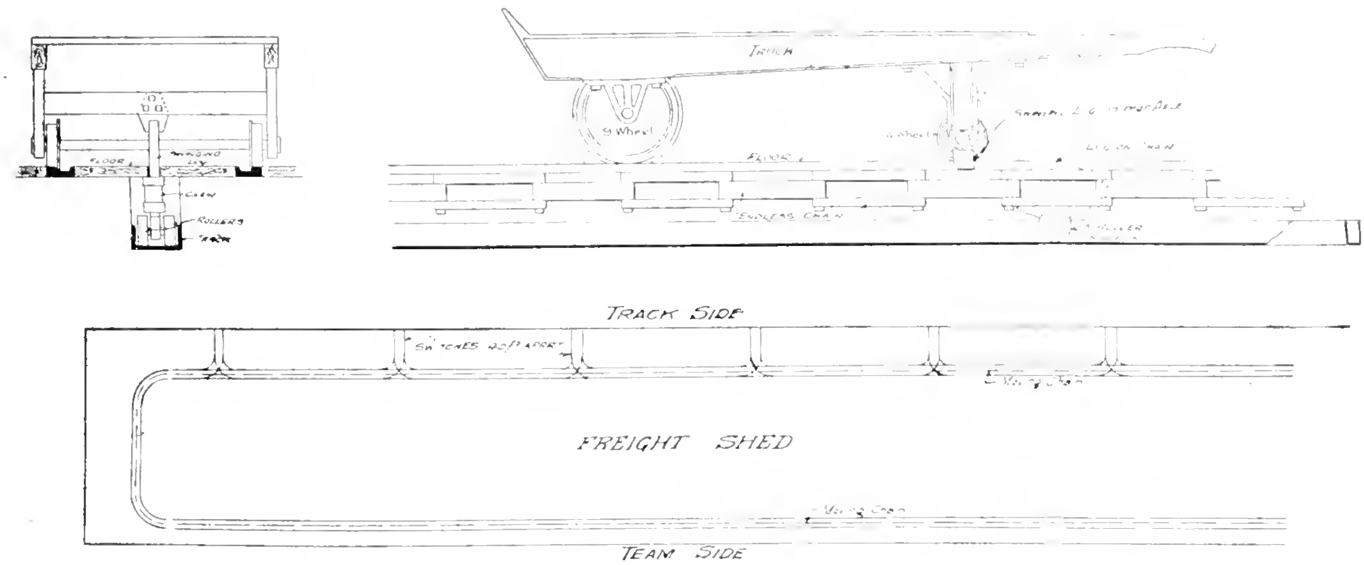

Fig. 7.—General Plan and Details of Chain Conveyer, with Truck in Position.

(6) The detention of cars in the terminal should be reduced to the minimum.
(7) It must be capable of being operated at high speed.

In general, the different kinds of plants for handling freight may be divided into four classes, viz.:—

(1) Conveyers.
(2) Overhead travelling cranes.
(3) Carrier systems.
(4) Motor trucks.

Whatever type is selected, it must be able to overcome the difficulties of coping with the great variety of shape, size and weight of commodities which it will be called upon to handle, also with the necessity of transferring the various packages from the teams to the cars, and from the cars to the storage platforms, or to the drays at the shed doors.

Conveyers.—There are quite a number of different types of conveyers in use for different purposes, such as roller, chain, belt, platforms, etc. These conveyers are very suitable for use where freight of one general class has to be handled on more or less fixed routes, such as are usual on steamship piers and transfer stations, but they are not adaptable to changing conditions.

roller chain is set in a space below the floor with an opening through the floor about one inch wide immediately over the centre of the chain. On either side of this opening running rails are set in flush with the floor, and in operation the truck is wheeled on to the track and when lined up the handle end is lowered and a swinging lug on the rear axle falls into the slot and is engaged by a lug on the chain which then pushes the car forward. Switches should be placed at about 40-foot intervals around the shed, as shown in the general plan in Fig. 7. This conveyer has been patented by a firm of conveyer manufacturers and is designed to travel at a speed of 60 feet per minute, carrying one truck every 12 feet, enabling the conveyer to handle about 100 to 150 tons per hour.

Roller gravity conveyers have been installed for special purposes, such as at the Minnesota transfer, near St. Paul, where large quantities of lumber and shingle are distributed from the cars by gravity over the lumber yard and warehouse.

The general opinion, however, with regard to these type of conveyers described above is that they are too limited in their capabilities to be really efficient in handling the great variety of package freight such as is usually met with at a general freight terminal.

Overhead Travelling Cranes.—Overhead cranes have not been installed to any very great extent for handling package freight, but they are serviceable for taking heavy and bulky loads over short distances and constant routes. They are very expensive to install, owing to the great weight of the moving parts and the heavy foundations and supports required. It has been suggested that a trucker could take his load to a crane which would then lift the truck with its load and carry it to its proper location in the house, the trucker returning to the car with the nearest empty truck, or it might be found convenient to have a narrow gauge track and car operated by hand from the track side door to the street side door. The crane could then handle this as easily as a truck.

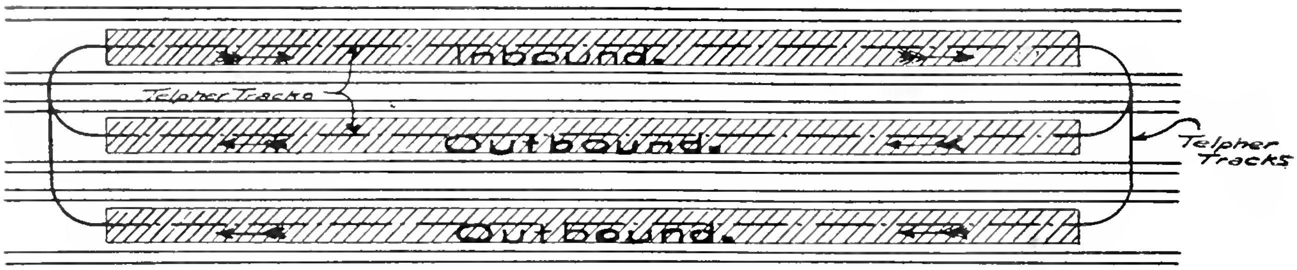

Fig. 8.—Plan Showing Telpher Tracks at Bergen, Sheds of Erie Railroad.

This scheme is as susceptible of development as that of the moving platform or chain, although the crane is liable to be more expensive both in installation and operation.

(To be continued).

THE EFFICIENCY OF COAGULATING BASINS.

Engineers who have had any experience with the operation of filter plants will find the paper recently read before the Illinois Water Supply Association by W. F. Monfort,, chemist of the St. Louis water department, both instructive and interesting. The St. Louis installation comprises a coagulant house capable of treating with lime and iron sulphate more than 160 million gallons per day with a series of unbaffled basins. There are no filters, but six basins of about 25 million gallons capacity; one of 40 million gallons, and two of 20 million gallons each. The water flows through all of them in series. The combined capacity of the system is 230 million gallons and the area about 250 acres. The system has been giving satisfaction ever since the World's Fair, but lately the suggestion has been entertained of supplementing with a filter plant the present treatment. Mr. Monfort's paper reads as follows:—

Capacity of the Plant.—It has been popularly assumed that the plant as now constituted is ample for the adequate treatment of an indefinitely large volume of water. One writer estimates the capacity of the plant at 250,000,000 gals. per day. Operating results warrant a much lower estimate based on the degree of success attained in treatment of varying quantities of different waters, ranging in suspended solids from 14 to more than 8,000 parts per million.

There is reason to believe that even in the first year of operation the clarifying system was overtaxed. The records of this laboratory afford but twelve determinations of suspended solids in river and clear well samples during the year 1904-1905, of which two must be discarded for obvious reasons. All are given in Table I. with consumption for their respective dates.

In the absence of any evidence to the contrary it is assumed that the scattered analyses are representative of the working of the plant. Treatment was begun on March 22, 1904; the first recorded result nine days later suggests the inadequacy of the plant, which then comprised but the six basins in series, to clarify 67,000,000 gals. per day when the suspended matter was 2,400 p.p.m. For 97.5 p.p.m. of suspended matter in the finished water indicates the introduction into the distribution system on the corresponding day, April 1, 1904, of 27.5 tons of suspended solids. It is possible that this result was abnormal, since mud previously deposited in conduits and clear well may have been loosened by the flow. The second result, two months later, shows improved working, but suggests that 75,000,000 gals. could not be handled properly when the suspended solids in the river exceeded 1,700 parts. According to present standards the only passable results in the first twelve months of operation are those of November 30, and April 1, 1905, when river solids were less than 1,000 parts, and the daily consumption was under 80,000,000 gals. Under other conditions the finished water contained notable amounts of solid matter. High consumption during the World's Fair period overtaxed the new clarification plant the entire summer. Still, these results show a vast improvement over conditions in the year prior to introduction of the lime-iron method, when the public was expected to make no complaint when 450 p.p.m. of suspended matter appeared in the tap water.

Table I.—Clarification Results for First Year of Operation, St. Louis Basins.

	Suspended solids.		Daily consumption in million
1904-1905.	River.	Clear well.	gallons.
April 1	2,442	97.5	67.5
May 30	1,717	25.0	74.5
June 30	3,753	32.5	87.9
July 30	1,694	43.6	95.6
August 30	800	15.0	89.8
September 30	1,268	22.0	91.1
October 31	578	12.0	81.7
November 30	376	2.0	77.3
December 31	208	10.0	71.2
January 31	181	—9.2	79.8
February 28	2,478	—4.4	73.7
April 1	990	0.0	70.4

In the second year of operation results are generally better. However, of 130 recorded determinations of suspended matter in clear well samples, 40 gave negative results. Figures given in Table II. are averages of 130 determina-

tions for river and 90 for clear well. Average daily consumption for each month is from high service pumping.

Compared with the new standard set by the previous year, these results are good. Apparently lower consumption favored better operation; although the occurrence of so many impossible results (negative quantities) makes interpretation difficult. The records show that from June to January, inclusive, high caustic alkalinity was carried in the treated water. This is perhaps the explanation of the high suspended solids recorded, which seem to indicate somewhat less than 80,000,000 gals. per day as the maximum capacity of the plant when the river was carrying 1,800 p.p.m. suspended solids.

The writer specifically disclaims any responsibility for the foregoing results of operation and analytical data. Results for subsequent years were determined under his direction and are believed to represent with a fair degree of accuracy the working of the plant. Averages are used in lieu of reciting the full detail of determination made on all save holidays. Inasmuch as total displacement of water in the entire basin system requires from 7 to 15 days, the averages by months of operation better represent the blended waters issuing from the clear wells to the distribution system. They are platted in Fig. 1, in sequence with those of 1905-1906.

The diagram shows graphically that when suspended solids in the raw water were below 1,500 p.p.m. and consumption did not exceed 75,000,000 gals. per day, the average suspended solids in the clear well water were usually not more than 1 or 2 p.p.m., increasing slightly with a rise in either river solids or consumption, and greatly with concurrent rise in both.

Table II.—Clarification Results for Second Year, St. Louis Basins.

	Average suspended solids. Parts per million.		Average daily consumption million gallons.
1905-1906.	River.	Clear well.	
April	.....	....	67.0
May	1,962	12.7	69.5
June	1,809	2.7	78.4
July	2,845	7.4	75.8
August	1,950	12.0	77.9
September	2,056	11.0	73.7
October	1,015	5.8	68.7
November	603	5.2	64.0
December	386	9.0	63.0
January	611	9.2	62.6
February	649	7.1	65.2
March	641	7.7	62.2
	1,320	8.2	69.0

It is noticeable that when pumpage was much above 75,000,000 gals. and river solids greatly exceeded 1,500 parts the quality of the treated water was seriously changed for the worse. In general, the curves of suspended matter in the treated water reflect the effect of high river solids and high consumption, following one or both in extreme cases, and illustrating the fact that these uncontrollable factors produce conditions which the present plant cannot meet. It appears that a raw water carrying not more than 1,500 parts of suspended matter can be made acceptable to the public of Saint Louis so long as consumption does not exceed 75 to 80 million gals. per day, but that the capacity of the plant varies inversely with the suspended matter.

The diagram further shows that from 1905 to 1910 consumption exceeded 75,000,000 gals. per day only in the summer and fall months, while in 1911 and [illegible] daily consumption has rarely fallen below this [illegible] time. The rise in river stage caused by rains of [illegible] spring and summer brings high average suspended solids [illegible] the raw water; for suspended solids vary with the stage. Coincident with these times of high turbidity comes the heaviest draught upon the distribution system, when lawns are to be sprinkled and the greatest waste of water occurs. It is, unfortunately, true that periods of highest turbidity are generally periods of greatest consumption.

Efficiency of Clarification.—There is abundant evidence that efficiency of clarification and bacterial reduction are conditioned by: Rate of flow through basins; amount of sludge already deposited; character and quantity of suspended solids in the raw water; temperature of water in river and basins; wind velocity and direction.

When a water properly treated is passed through the settling basins, 97 to 99 per cent. of the suspended matter is precipitated in the first basin, the percentage removal depending upon the character and quantity of solids contained, the temperature, wind velocity and direction, and the amount of sludge in the filling basin. In passing succeeding basins the remaining suspended matter undergoes a further reduction of one-half or one-sixth; corresponding to a few hundredths of 1 per cent. reckoned on suspended matter in the raw water, likewise dependent upon velocity, size of particles, wind and temperature. The major portion of clarification is, however, accomplished in the filling basin of 25,000,000 gals. working capacity. There is no provision for applying chemicals after water enters the basins. Efficiency of the plant, therefore, depends primarily upon the volume of water which can be satisfactorily clarified in the filling basin.

The weight of suspended matter in the effluent of successive basins varies with the weight of solids carried by the raw water. The percentage is approximately constant; the actual weight of solid matter remaining in the finished water is proportional to that originally present in the river water.

TABLE III.—SUSPENDED SOLIDS IN EFFLUENT OF SUCCESSIVE BASINS

	Parts per million	Per cent removal	Parts per million	Per cent removal	Parts per million.	Per cent removal.	Parts per million	Per cent removal
River	1,444	..	3,000	..	4,500	.	1,000	
Basin 1	14.0	99.01	47	98.5	9[illegible]	98.0	25	99.75
Basin 2	12.1	99.16	21	99.3	50	98.8	20	99.80
Basin 3	8.4	99.4	14	99.5	37	99.2	10	99.9

Basin 5	5.8	99.6	10	99.7	15	99.7	7	99.95
Basin 6	5.6	99.6	[illegible]	99.7	15	99.7	5	99.95
Basin 7		..			..	.	5	99.95
Basin 8		.				.	5	99.95
Pumpage	70		80		50		120 million gal.	

The results in Table III. are from the records of periods when pumping was constant. Since the course of currents will vary with changing rates, and the velocity and consequent carrying powers of currents increases with increase in pumping, the weight of suspended matter carried over the first weir is subject to wide fluctuations. A change in pumping from a rate of 60 to 90 million gallons per day has increased the suspended matter in the treated water (clear well) by from 2 to 7 p.p.m., and a further sudden increase to 120,000,000 gals. per day has caused a further rise of 10 to 13 parts, which was carried through the entire series of basins and conduits to the clear well, where 25 to 30 parts of solids in suspension occurred.

Slight changes in temperature suffice to alter the course of currents through the basins. In the spring, when the temperature of water in the river and basins is rising, the sludge is less subject to disturbance than in the fall and early winter, when, with falling temperature, the influent water, more dense than the warmer water of the basins, passes downward over the sludge, causing it to carry over weirs.

In the fall, with lowering atmospheric temperatures, the sludge and water in the bottom of the basins are sometimes 1 degree Fahrenheit or more warmer than surface water of basins and river. Circulation is then effective in changing the course of influent water currents, making them deeper and increasing the scour.

The sludge is further subject to disturbance by wave action when high winds prevail, a frequent occurrence in March. In such case the amount of suspended matter carrying over the weir from the filling basin shows a marked increase. Our basins have a working depth of about 14 feet. Similar effects of wave action have been noted in other reservoirs 18 feet deep.

The basin at the Chain of Rocks (52 acres) are all uncovered, all used in series, and therefore, subject to disturbance by each of the agencies affecting their successful working.

Character of Sludge.—Suspended matter with the coagulum produced by chemical treatment subsides rapidly, undergoing a change in volume during its accumulation in the bottom of basins. When freshly formed it is loose, disseminated through the full volume of water in which it forms; under average conditions after 1½ hours it occupies about 3 per cent. and after 24 hours about 2 per cent. of the original volume. After this lapse of time only the newly precipitated portions are disturbed by gentle currents.

Opening mud gates at 8-hour intervals seems to reduce the sludge only near the gates, since it follows in a general way the contour of the bottom of the basin and is of such consistency that it does not flow readily over the compact material of earlier subsidence. The tendency is for each new deposit to collect more thickly upon the highest points of previous deposits.

Bacterial Removals.—Bacterial purification, as shown in Table IV., is proportional to the degree of clarification, falling a little below the percentage removal of suspended solids for the reasons which are cited below.

Table IV.—Removal of Bacteria With Suspended Solids.

	Suspended solids. Parts per million.	Suspended solids. Per cent. removal.	Bacteria per cu. cm.	Per cent. removal.
River	1,444	.....	57,000	.....
Basin 1	14.0	99.01	933	96.1
Basin 2	12.1	99.16	.....	.....
Basin 3	8.4	99.4	500	99.1
Basin 4	7.1	99.5	.....	.....
Basin 5	5.8	99.6	100	99.8
Basin 6	5.6	99.6	.....	.....
Clear well	2.6	99.8	42	99.99

Bacteria entangled in the natural sediment of the water, and gathered into coherent masses with the coagulum, concentrate in the sludge to the extent of 1,000,000 or more per cu. cm.; they are subject to disturbance and dissemination through basin contents by varying currents, however produced, and are easily carried through latter basins to the clear well.

It has been observed that slight changes in temperature of the influent water, causing almost infinitesimal differences in the density from that of water at different levels in the basins, give rise to turbid, polluted effluents from each basin in series, as the less compact layers of sludge are moved; that overturning, which in large bodies of deeper water occurs but twice a year, may occur several times a week when warm and cold days alternate in spring and fall; and that with a slight rise in suspended matter carried from the older sludge in the filling basin may come an altogether disproportionate increase in bacteria, by reason of alterations in the rate of pumping, or the currents produced by high winds sweeping along the surface of a half mile of water. When it is considered that the combined surface of water exposed to winds and temperature changes is more than 52 acres it will not seem idle to refer to what might at first appear entirely negligible factors. See Table V.

An abrupt change in the rate of flow through basins may cause the sludge to carry its burden of bacteria through successive basins, e.g., on August 17, 1912, such a change occurred, followed on the 19th by the appearance in the clear well samples of contamination with organisms of the B. coli group.

Change in the direction of flow incident to cleaning and restoring a basin to service affects both suspended solids and bacteria per cubic centimeter in the finished water. Basin 1 was thus put in service June 6, 1912. The rise of bacteria in clear well samples was from 150 per cubic centimeter on the 6th, to 3,300 in the following week. In this case irregular pumping (at rates ranging from 70 to 120 million gallons per day) was a factor in producing bad results.

Table V.—Effect of High Winds on Bacterial Counts.

	February 17. Bacteria per c.cm.	February 17. Per cent. removal.	February 24, 1909. Bacteria per c.cm	February 24, 1909. Per cent. removal.
River	24,500*	.....	33,700*	.....
Basin 1	1,550*	93.67	2,470*	92.68
Basin 3	1,000	95.92	890*	97.36
Basin 5	338	97.80	820	97.57
Drawing gate	720	97.06	2,960	91.22
Terminal chamber	1,325	94.59	3,475	89.70
Tap	6,563	73.21	13,750	56.26

It is apparent that bacterial reductions are subject to disturbance from too many factors to give constant results. We have no safeguard against turbid, contaminated water under these conditions. Table VI. shows the disproportionate increase of bacteria released by stirring previously deposited sludge.

River samples usually give evidence of the presence of bacteria of the B. coli group in 1,100 cu. cm. The finished water has given counts of more than 30,000 bacteria per cu. cm. on gelatine at 20 per cent. C., and members of the B. coli group have been found in 6 per cent. of tests on 1 cu. cm. samples in a single month.

Table VI.—Bacterial Increase in Clear Well After Basin Cleaning.

1912.	Suspended solids.	Bacteria per c.cm.	Per cent. removal.
June 6*	15	150	99.6
" 7	12	250	99.6
" 8	14	300	99.4
" 9	..	....	....
" 10	11	775	98.2
" 11	12	1,100	97.2
" 12	10	475	98.6
" 13	11	2,075	93.0
" 14	9	1,500	94.8
" 15	10	3,300	92.9

In reviewing bacteriological results for past years there is noticed a very wide divergence at any one sampling point, and extremely irregular counts for a given period at various points in the clarification system. The utmost we can hope for is a large percentage reduction of bacteria. We can have

*Note—Bacteria of the B. coli group present.

no assurance that the water which enters the distribution system will be free from pathogenic organisms regularly. While the improvement in the character of the effluent since the introduction of the clarification scheme seems to have reduced the typhoid death rate, the quality is still far from that of a good filter plant.

Residual Solids in Distribution System.—Water leaving the clear well contains small quantities of suspended and dissolved iron compounds, small particles of calcium and magnesium compounds, and larger quantities of silt and silicious matter too fine to be deposited during rapid flow through the sedimentation system. The amount of this material daily introduced into the distribution lines during the first year of operation, calculated from suspended matter and daily consumption, was as high as 27.5 tons, averaging 8.7 tons per day for the ten analyses referred to above. See Table VII.

This material is intermittently discharged from taps over the city in a very irregular way. At the laboratory of the city chemist samples are collected daily for analysis. Comparison of suspended solids in the clear well and at this tap illustrates the extent of this irregular deposition and displacement, as shown in Table VIII.

It is a matter of common observation that after unusual draught upon the mains in a portion of the system, very high turbidity appears, local, or affecting large sections of the city, according to the degree of the disturbance. Following a large fire complaints of turbid water are very numerous. So long as our practice continues sedimentation in the mains, the department cannot resent protests of consumers at turbid water when the accumulated solids are intermittently flushed out.

Table VII.—Average Weight of Suspended Matter in Daily Supply.

	Solids in tons.	Consumption in million gals.
1904-1905	8.7	79.0
1905-1906	2.35	69.0
1906-1907	1.05	70.1
1907-1908	0.31	68.9
1908-1909	0.5	70.7
1909-1910	0.34	75.4
1910-1911	0.92	76.1
1911-1912	1.74	83.5

Incrustation in Distribution System.—Because ours is a partially softened water there is always a certain variable amount of calcium carbonate present in the finished product. The softening process is completed slowly at summer temperatures and in winter is incomplete even when the water passes to the distribution system. There is, therefore, more or less deposit of calcium carbonate in mains and service pipes. Even with high bicarbonate alkalinity in the filling basin the water leaving the sixth or ninth basin is still supersaturated with calcium carbonate.

Connection with a 7-foot steel flow line was made in January, 1908, and the city supply drawn through it for 74 days. Examination at the end of the period disclosed a deposit, principally of calcium carbonate, 1/16 inch thick when moist, which shrank to 1/32 inch in drying. The water had an average total alkalinity of 59 p.pm., of which 25 were due to neutral carbonates and 34 to bicarbonates. Temperatures ranged from 32 degrees to 47 degrees Fahrenheit.

During the earlier years of operation there were notable deposits in meter gears, fish-traps and the like.

While the deposit in the distribution sys[illegible] n[illegible]t now seem to be increasing rapidly, there is [illegible] crustation in progress, due to the blending of unequ[illegible] ened waters. Trouble from this source can be lessened [illegible] longer storage, which will equalize the quality of the wat[illegible] before passing the high service pumps—a very costly expedient; or by so regulating the degree of softening that the finished water shall show a high degree of uniformity—a difficult matter when the raw water is changing quickly. Lower regular velocity through the settling basins would allow longer time for softening reactions; this entails the use of several filling basins, instead of but one with the rest in series. Finally, further reduction of this trouble could be effected by changing the order of chemical treatment, adding lime first and agitating the treated water before the charge of iron sulphate is applied.

Fig. 1.—Diagram Showing Relation of Consumption to Classification, St. Louis Waterworks.

There are several methods of arriving at a standard of judgment for considering the efficiency of coagulating basins as full and final preparation of water for distribution to consumers; comparison of the quality of the effluent with respect to clarity and bacterial content (a) with that of the previous supply, (b) with untreated water from day to day, or (c) with the effluent of a well operated filter plant.

Table VIII.—Intermittent Sedimentation in Mains. Suspended Solids in Parts per Million.

March	12	8	12	6

During the first year of operation at Saint Louis the weight of solid matter carried into the distribution system averaged 25 p.pm.—ranging from none to 97 parts; the reduction was about 98 per cent. reckoned on the weight of solids in the raw water. While this was a decided improvement over conditions prior to treatment the introduction of an average of 8.7 tons of suspended matter per day into the mains left much to be desired if one compares this result with the standard set by a satisfactory filter plant, whose effluent contains no weighable quantity of solid matter in

suspension, and shows no visible turbidity or opalescence in bright sunlight.

The local standard of purity has advanced from year to year since the clarification system has been in operation. Prior to 1904 sedimented water containing 60 to 450 p.p.m of solids in suspension was accepted, if not approved. Compared with that standard, the quality of water furnished in 1904-1905 was excellent. The next year showed a marked improvement, and established in turn a standard for comparison of the succeeding year's supply. With each subsequent year the quality of water furnished has been progressively better, until 1910-1911, when consumption so far exceeded the plant's capacity that there was a falling off in the quality of the effluent, although it was still superior to that supplied before 1907-1908. The capacity of the present plant must be increased. The extensions and changes made must provide a better effluent than the present public has been educated to demand.

It is apparent that the addition of a filter plant to the coagulating basins is essential if the residual sediment is to be finally removed, and the high color which sometimes characterizes the raw water is to be reduced to an acceptable degree. Operations under prevailing conditions in a plant of this size and character do not admit of the close control possible in a filter plant, where the units (filters) are small, subject to immediate supervision and washing, and their output regulated by rate controllers. Furthermore, with filters the solid matter collected with entangled bacteria is quickly and permanently removed from water passing through them; whereas coagulating basins give too frequently only a temporary separation. It is manifestly impossible to interrupt the flow through any one basin at will, should the water in it prove unfit for use, without seriously affecting the contents of other adjacent units by altering the course of currents through them. Nor is it possible to wholly eliminate the previously accumulated sludge in filling and sedimentation basins, so that after cleaning the first water passing through them shall be faultless.

With seven filling basins and six additional new reservoirs for sedimentation, as considered in a report made by the writer, there would be effected at best only a percentage reduction of suspended solids and bacteria, with no assurance of a safe, clear, sparkling effluent. Irregularities incident to a plant of this character, where pumping and drawing and the consequent period of sedimentation are subject to wide variations directly affecting the finished water, can be avoided only by filtration.

The abridged form of treatment adopted prior to the World's Fair has beyond question served a very useful purpose. The question has arisen whether the present system of partial softening, coagulation and sedimentation shall be extended by adding further sedimentation basins to the already existing plant, or supplemented by a filter plant which shall afford a perfectly clear water at all times, with fairly constant bacterial removals and the possibility of immediate control of operating conditions. The cost of constructing two basins of 40,000,000 gals. capacity each was about $7,500 per 1,000,000 gals. capacity.

It is hardly possible to make the necessary changes in present basins and add the required reservoir capacity to provide for clarification of the volume of water which will certainly be consumed within the next ten years at a cost of less than $1,500,000. Whereas a filter plant added to the present basins with certain changes outlined comprising 40 filters of a normal rating of 44,000,000 gals. in 24 hours, can be constructed at a cost of about $1,250,000.

There are locations where basin construction is cheaper, where prolonged sedimentation in very large reservoirs may be advantageously used in producing an acceptable effluent for a time—until the public forgets its earlier satisfaction with an improved water supply, and clamors for further betterment. Before such installations are begun there is need of very careful study of the quality of the untreated water, to show its adaptation to coagulation methods and good judgment as to arrangement of the plant with a view to the ultimate addition of filters.

CONCRETE SWIMMING BATH AT SOUTHAMPTON.

By J. A. Crowther, A.M. Inst. C.E.*
(Borough Engineer and Surveyor, Southampton.)

The original bath, which was constructed some years before the writer of this paper came to the town, was presented to the Southampton Corporation by Mr. Tankerville Chamberlayne, Member of Parliament for the Borough.

The bath was originally 156 feet long by 30 feet wide, having a depth of 6 feet. The ground proved to be very treacherous, being on the bank of the River Itchen at Northam, and the bath was, and is, filled by the rising tide. Therefore, it will be seen that two forces must be provided for: (1) When the tide is out and the bath full of water; and (2) when the tide is high and the bath empty.

To meet the requirements of condition (2) it is evident that the bath must be securely anchored to the bed of the river to make sure that it shall remain in position when empty, and a high tide prevails, otherwise the bath might go sailing gaily down the river, possibly to the detriment of shipping.

Soon after the old bath was brought into use cracks in the walls and floor developed, and to such an extent that it was found to be impossible to keep the water in the bath when the tide was out.

Tests were made by closing the inlet valve, and allowing the tide to rise outside. The result was that as the tide rose a distinct tremor could be felt by any person standing on the edge of the bath. Further it was found that wooden wedges loosely inserted at low water and with the inlet valve closed, could not be withdrawn by hand when the tide had risen.

Under the above circumstances the author could not advise the Borough Council that it would be safe to use the bath, even when it contained a sufficient quantity of water.

In February, 1903, the author submitted two schemes to the Baths Committee for reconstructing the bath, and making adequate provision for withstanding the forces arising under the two conditions to which reference has been made.

Scheme 1 was for ordinary elm piles with a concrete superstructure.

Scheme 2 was for ferro-concrete on the Mouchel-Hennebique system throughout.

The estimate for Scheme 1 was $5,106.03, and that for Scheme 2, $4,623.90, and, being distinctly of opinion that ferro-concrete work will last as long or longer than ordinary timber piling, the author advised the Council to accept Scheme 2.

On account of expense, and in order to obtain better foundations, it was decided to construct the new bath of

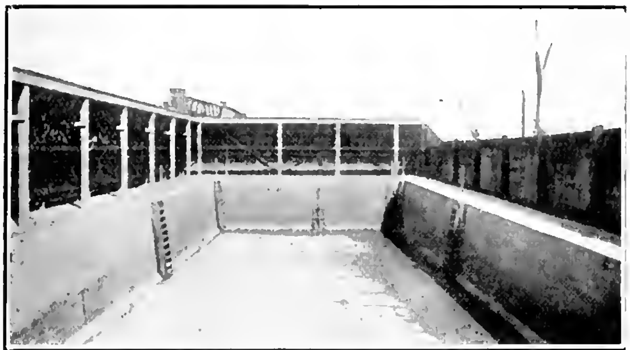
* From a paper read before the Institution of Municipal and County Engineers, England.

smaller dimensions than the first one, this being done by curtailing the projection of the bath into the river.

The dimensions of the new bath are 75 feet by 30 feet, by 7 feet deep at one end and 4 feet 6 inches deep at the other, having also a filter or straining chamber 30 feet long by 10 feet wide.

The greater part of the old bath was removed, but the side walls of the remainder were left so as to provide a promenade for the new part, care being taken to ensure the proper bonding of the old and new work.

Method of Construction of the New Bath.—The whole bath and filter are carried on twenty-two ferro-concrete piles, 14 inches square by 32 feet long, longitudinal ferro-concrete beams, 5 inches wide by 10 inches deep, spaced 4 feet 10 inches apart, centre to centre, and ferro-concrete cross-beams, 7 inches wide by 10 inches deep, laid 9 feet 4 inches apart, centre to centre. The specification provides that in the driving of the piles the set should not exceed half an inch for the last ten blows of a 30-cwt. monkey falling 30 inches.



Open Air Swimming Tank.

The formula used for calculating the resistance of the piles was the usual one of L = WH/8D.

Where L = Safe load on pile in tons, W = Weight of monkey in hundreweights, H = Fall of monkey in inches. D = Set of pile in inches.

The set of every pile was carefully observed, and hereunder will be found a few examples:—

Pile No.	Length of pile. ft. in.	Length driven, ft. in.	Set, in.
11	32 0	28 9	⅛
12	32 0	28 0	½
13	32 0	27 6	½
14	32 0	26 9	½

It will be noted from the above table that, although the piles were made 32 feet long, the distance driven was from 26 feet 9 inches to 38 feet 9 inches, at which depth the required resistance was obtained.

The concrete was then stripped off the projecting portion of the piles, and the steel bars bent over and thoroughly interlaced with those of the horizontal and cross-beams.

The floor and walls are 4½ inches thick. The concrete walls of the old bath (before referred to as being left as a promenade), are carried on the cross-beams, which were continued through the pile heads, and about 15 inches under the old walls. A chase was then cut vertically in the old concrete wall and the cross-beam continued upward on this chase as a counterfort. The steel work of the whole structure, including the piles, beams, floor and sides, was all tied together and interlaced by means of straps and the main bars, so that the whole was securely bound together.

The piles were made in wooden moulds laid horizontally, and the reinforcement of each pile was made up of four 1¼ inches diameter bars running the entire length of the pile, these bars being braced together with links or stirrups of 3-16-inch diameter. The steel work was first placed in position so as to leave a space of about 1½ inches (not less than 1 inch) between the steel and the wood framing, in order that the concrete might entirely surround the metal and preserve it from the action of sea water. The mould was then filled up and carefully punned so as to make a solid mass.

The piles were turned in about fourteen days, and then left for further seasoning. When considered to be sufficiently hardened, the piles were placed in an upright position for driving, and in this position the atmosphere could play on all four sides of the pile, and so quicken the process of seasoning. While in the vertical position each pile was watered every day before being driven.

As it was necessary to complete the work as soon as possible, some piles were made up with concrete in the proportions of 1 part of Portland cement to 3 parts of sand and aggregate, and driven three weeks after having been made.

The specification provided that the concrete for the piles should be in the proportion of 1:5, and that for the sides, floor and beams in the proportion of 1:4. The specification for the concrete was very stringent. All the cement was carefully examined and tested for specific gravity, fineness of grinding, tensible strength and soundness. Care was also taken to secure clean aggregate.

Well knowing the difficulty of securing good concrete work in tidal waters, and especially in Southampton, where we have four tides to be contended with each day, the author attached much importance to securing a good contractor, and to a stringent specification governing both workmanship and materials.

The first condition was secured by adopting the Mouchel-Hennebique system of construction, as this firm insist upon their work being carried out by licensed contractors, which, of course, means that none but good and experienced men are employed.

The specification provided that upon the completion of the work the bath was to be charged with water to high water of the highest spring tide, and to remain so for at least forty-eight consecutive hours; then to be left completely empty for the same period, and to remain perfectly watertight and sound in every detail under these conditions before the engineer would give his certificate as to final completion, and that the contractor should maintain the bath in such watertight condition for a period of twelve calendar months. Although the contractor experienced great difficulty in doing this, he succeeded and left the bath as specified.

The view reproduced in the accompanying illustration shows the new bath when empty.

REINFORCED CONCRETE COALING STATION.

A locomotive coaling station of reinforced concrete of 2,000 tons capacity, has recently been built for the Philadelphia and Reading Railway at Philadelphia. The building, which spans seven railway tracks, is supported on seven rows of five columns each, and one end row transversely, the rows of columns being parallel to outer lines of tracks. The floor of the bunkers is of sufficient height above rail level to permit the largest engines to take on coal and discharge ashes.

GAS DISTRIBUTION IN TORONTO.*

By D. L. Hill.

[NOTE.—Municipal engineers are frequently confronted with real problems caused by gas mains crossing the underground work of other corporations, such as telephone, conduits, water mains, etc., and it is felt that the paper printed herewith will prove of considerable interest to many of our readers who are coming in contact more or less frequently with this difficulty.—Ed.]

In taking up the subject of gas distribution, the question is so broad and the time at my disposal so brief, that nothing more than a mere synopsis can be given of the various operations connected with this branch of the industry. For this reason I have divided the subject into sections, so as to be more easily understood and followed.

The view of the lantern slide shows the trunk main system of Toronto, and is confined to cast iron pipe only.

Street Mains; Their Functions.—Street mains bear the same relationship to the gas company as the delivery wagon bears to the merchant; they both deliver to the point of consumption the commodity sold. It is a noticeable fact that a mercantile house doing a large volume of business covering a wide area, has delivery wagons made of various sizes. For local delivery, small one-horse wagons are used, but for suburban and interurban delivery, large trucks and vans are employed with a capacity several times greater than for local duty.

The analogy is apparent when applied to gas mains, hence the diversity of sizes. The large, or trunk mains, as they are usually called, carry the gas away from the holder to the distant points of consumption, the intervening territory being interlaced with what might be termed intermediate trunk mains, which are fed by the larger ones. These intermediate trunk mains divide the city into sections, comprising many streets and blocks, and it is from these intermediate mains that the service mains derive their supply.

Sizes of Mains.—The sizes of the various feeder mains are determined by Pole's formula for the flow of gas in pipes when the quantity, or volume, of gas to be delivered is known, but, unfortunately for the gas engineer, this is not always obtainable, for oftentimes large building operations are launched in isolated sections of the city which develop quickly into an area of large consumption, a condition which in no way could be pre-determined. Therefore, unless the feeder mains have been laid of ample capacity, the company would be put to considerable trouble and expense to meet the increased demand, so that the decision as to size of these mains rests largely upon a question of judgment born of experience and knowledge of local conditions.

The size of service mains is determined more from the standpoint of durability and economy than of capacity, for in the majority of cases where 4-inch mains are laid a 2-inch or 3-inch would amply supply the maximum demand, but owing to the structural weakness of the smaller sizes, causing the supply to be frequently interrupted by breaks, stoppages by "trapping," etc., attended by the necessity of immediate and expensive repairs, it is more economical to adopt a liberal policy regarding the sizes of service mains; the company's rule being to lay nothing smaller than 4-inch.

Peak Load, or Maximum Demand.—The question of maximum demand might be of sufficient interest to mention in passing. If it were possible for the daily consumption to be uniform for each hour of the twenty-four, it would mean a great economy to the company in street mains, but the mains must be of sufficient capacity to meet the demand at "peak load." By referring to a Bristol recording gauge chart it will be noticed that the time of this increased demand is variable, but in general it occurs between the hours of 5 and 7 p.m. daily, during the fall and winter months, due to the overlapping of lighting, industrial, and domestic loads. The extreme "peak load" will cover a period of perhaps 15 minutes, in which time the consumption is increased many times over any other similar period out of the 24 hours, necessitating a severe tax on the main system, while some other periods of the day have practically no consumption. To increase the consumption of gas during these "off periods" is a desideratum which is vigorously encouraged by the company through the sale of industrial appliances, thus bringing a return from a heavy investment in a main system at a time when it would otherwise be earning little or nothing.

Main Laying.—Mains should be laid in a straight line and of sufficient depth so that it will preclude any possibility of disturbance, either from street traffic or climatic changes. The first consideration can be omitted, for if a main is laid below the normal frost line in this climate the possibility of disturbance from street traffic is very remote, besides, our mains are laid chiefly between the curb and the street line, so that heavy traffic could only affect the mains at street crossings. The custom is to lay mains four feet below the surface and of the same grade as the street, but in many cases the mains are laid in advance of street grading, in which event the main is laid to a grade of 2 inches, approximately, for every 100 feet. When the grade reaches a level of one foot, more or less, below the normal depth, a "drip pot" is set, from this point the grade of the main is upward until the summit is reached at normal depth, when the grade again is turned downward. The necessity of this gradient is due to the fact that the aqueous vapors held in suspension in the gas while in the holder are thrown down, or condensed, when subjected to the varying temperatures of the street main. This condensation then flows to the "drip pot" by gravity, to be pumped out at intervals.

The trench should be no wider than is necessary to lay the main, which should rest on good firm earth, for if it sags or settles, the condensation finds lodgment there, thus restricting the flow of gas, or completely obstructing it if the sag is deep enough. After the trench is ready to receive the pipe, the spigot end is brought home into the bell of the preceding length, care being taken to see that the bell and spigot end are perfectly clean before entering. This jointing space is then filled to within 1½ inches to 2½ inches of the face of the bell (the depth varying with the size of the pipe) with jute yarn twisted into a rope of sufficient size to completely fill the joint space, after which it is driven up hard with hammer and yarning iron so that it is gas tight. The remaining space is now filled with molten lead. This operation is performed by placing a lead rummer, or dam, made of asbestos rope, around the pipe immediately in front of the bell, the ends being turned out and held by a clamp, leaving a triangular space for the "gate" through which the lead is poured When cool, the lead runner is removed, the lead forming a fillet, outside the bell, which is then upset with a hammer and cold chisel, followed with caulking tools of varying thickness until the last or finishing tool completely fills the jointing space. When the joint is finished the lead is flush with the face of the bell.

In general, mains should be laid with as few bends as possible. In turning sharp curves the pipes should not be "broken" or swung over at each joint until the desired curve is reached, but circle bends should be used, for it is

* Paper read before the Consumers' Gas Company Educational Association meeting, April 8, 1913.

impossible to make a good joint when the pipe is not in line. At the junction of intersecting streets special pipe castings are placed so that at any future time it might be necessary to make a connection with this main, an outlet is ready, thus obviating the necessity of cutting out and inserting a branch.

Leak Work.—No matter how carefully the main laying is done, leaks are sure to develop, for it must be borne in mind that the gas company has only the same rights as any other corporation enjoying the privilege of using the streets for their underground operations. In a densely populated city, like Toronto, the underground work of other corporations frequently comes in contact with our mains, thereby disturbing the earth surrounding them. In the course of time through the settlement of the newly filled trench, our main is carried down with it, attended by leaky joints and frequently causing a break.

As soon as the report of a leak in the street is received, a survey of the surrounding territory is made immediately to locate its source. It might come from a dozen causes, such as broken stand-pipes, defective house piping or fittings, leaking meter, etc., any of which is comparatively easy to find and repair, but a leaking main or service requires different treatment, and is frequently attended with no small amount of danger, particularly if the main is in close proximity to some other foreign structure such as an electric conduit, or telephone duct. As these structures are not tight enough to prevent the gas from entering, it is liable to be carried long distances from the source of the leakage and its presence is manifested at the nearest manhole. The accumulation of gas in this confined space only requires a spark to create an explosion, at times resulting in serious injury to life and property. When the leak is in a street where no such foreign structures exist, it is usually found by "barring" over the main. This operation consists in driving a steel shod bar through the earth over the main, the leak being detected by the odor coming from the opening after the bar is withdrawn. If the leak is found to be at a joint, the lead is merely recaulked, but if the main is broken a temporary repair is made by wrapping the fracture with a bandage of soaped muslin until a split sleeve can be procured and put into place, i.e., if the break is of such a nature that it can be repaired in this way. A "split sleeve" is what its name implies—a sleeve, split or divided through the centre, and held together by bolts through flanges cast on either side.

To place a split sleeve in position, the main is scraped thoroughly clean, and millboard, after being softened in warm water, is placed between the flanges, the bolts are inserted and the nuts brought up tight, so that the millboard is compressed into any unevenness in the iron, which, when dry, gives a permanently tight joint. The jointing space between the sleeve and main is made up by first driving in jute yarn, which is then followed by molten lead, similar to an ordinary bell and spigot joint. If the break is longitudinal, the affected section of pipe must be removed and a new piece inserted. This operation necessitates the interruption of the gas supply, if the main is fed from one way only, in which event the consumers affected must be notified that the gas will be shut off while repairs are being made.

The gas is shut off when repairs or the connection of two mains are being made, by drilling a hole in the main of sufficient size as will admit a rubber bag. This bag is made of thin sheet rubber, from one to two inches larger than the diameter of the main, to which a hose is attached for inflating. For the smaller mains the bag can be easily inflated by placing the end of the hose to the mouth and blowing, but for larger mains a "stopper" is usually employed in conjunction with the bag, the bag being inflated with [illegible] air pump.

The "stopper" consists of two flexible strips of whalebone to which is fastened oiled canvas of the diameter of the pipe. When pressure is exerted on the ends the centre portions spring outward in the form of a hoop, bringing the oiled canvas taut, thus relieving the gas pressure from the rubber bag.

Services.—It is through the service that the consumer receives his supply from the street mains. The company install all services gratis when the building is on the street line, but if the building sets back from the street line a small charge is made to run the service from street line to building, being merely sufficient to cover the cost. It is the policy of the company to maintain these services and ensure the consumer an adequate supply permanently, even if subsequent appliance installations would render it necessary to lay an entirely new service in addition to the one already in place.

The considerations affecting the size of pipe to be used for services are, generally speaking, maximum demand, distance from main, and economy of maintenance. By taking into account the number of outlets or gas-consuming appliances, and assuming them to be all in use, the maximum demand is easily computed. The length of service to be run is known, and its size is readily determined by the use of Cox's gas flow computer, which is a circular slide rule, as it were, which graphically solves Pole's formula for the flow of gas in pipes. But in this relation it will be found in the great majority of cases a one-inch or even a three-quarter pipe would meet all requirements regarding size for ordinary dwellings, while the question of economy would dictate a larger size. The prevailing practice is to lay no services smaller than inch and a quarter. The small extra cost of this size pipe over the smaller sizes is not a very large percentage of the total cost of the service, while it will provide for a possible increase in the amount of gas required. Its greater weight also adds considerably to the life of the service and is not so susceptable to become "trapped" by condensation due to settlement. The pipe is coated with a coal tar preparation before being laid.

The service is connected to the main by means of what is termed a "street tee" and "ell," which, when connected, forms a swing joint, thereby relieving the strain on the street main in case of any movement. The service is connected by drilling and tapping a hole in the upper side of the main in which is inserted the street tee. A wood or rubber plug is placed in the open end of the tee, thus shutting off the gas from the service until the work is completed, when it is removed and replaced with a screw plug. In making the hole in the main the old method was to chip a hole in the pipe with a cape or diamond pointed chisel, as close as the eye could judge for size, after which it was reamed and tapped. This method is not unknown to-day, but the practice must be discouraged, for in case the hole is chipped too large, it will not permit a full thread to be made when tapped, in which event the hole is made a size larger, subjecting the workman to the danger of being overcome by escaping gas, not to mention the weakening of the main thereby. A very ingenuous device which is in general use to-day drills and taps the hole in one operation with little or no escape of gas.

The service is laid on solid earth with an incline towards the main so that any condensation from the gas will not be carried into the building. Anyone who has ever encountered the odor of this condensation in the house will appreciate this precaution.

House Piping.—This is a branch of the business over which the company has little or no control, except in an advisory capacity. The house piping is usually installed by a steam-fitter or plumber while the building is in course of erection, and is too often left to his discretion as to size, etc. In the interests of economy, without regard for the duty they are to perform, the pipes installed are usually too small, in which event the gas company is condemned for not furnishing an adequate supply when the whole trouble rests with the house piping.

Various tables or rules are in use setting forth the minimum sizes of house piping which should be used, based upon the knowledge of the quantity of gas to be supplied, through a given length of pipe, with an allowable drop in pressure of 1/10 inch for every 50 feet. The necessity of some regulations relative to the size of house piping has been brought home very forcibly through complaints of insufficient supply that the company is now co-operating with architects and builders in this respect, in order that the consumer shall have an ample supply for any additional requirements.

As the question of meters was discussed at a previous meeting, I will not touch upon that branch of the business here.

AN INTERESTING EXCAVATOR.

We present herewith two illustrations of a rather interesting machine which is now engaged at the works of the Tofield Coal Company, at Tofield, Alta. This machine is capable of excavating at a high or low depth from six to nine meters, and giving an output of 1,100 cubic yards in light dry soil.

It is worked on the continuous bucket system, and has a bucket at every sixth link. These buckets work in a guided ladder which is pivoted at the inner end to the body of the machine, and suspended by wire ropes from steel jibs, and can be raised or lowered as required.

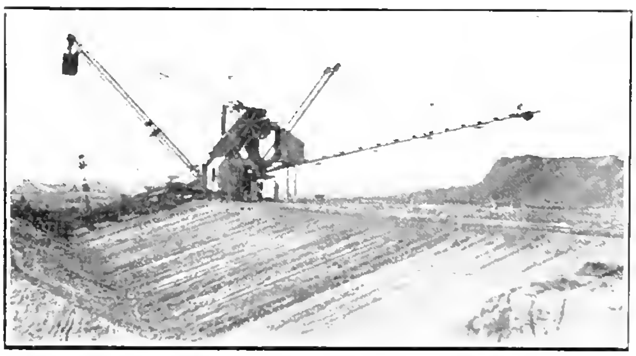


Fig. 1.

The chain of buckets is worked by a hexagon tumbler at the top of the machine, and the buckets empty into a hopper as they pass over the tumbler on which is fitted a cleaning knife to ensure the emptying of the buckets.

The hopper guides the excavated material on to a belt conveyer 26 meters long, which works at an inclination of 15 degrees.

The whole excavator is supported by springs on twelve wheels running on a track consisting of three 90-lb. rails.

The power is derived from a horizontal tubular boiler and twin cylinder engine, and all the motions of the machine are derived from this engine, and they consist of the following movements: Travelling of the machine backwards or forwards; lifting or lowering the bucket ladder; stopping or starting of the buckets (all controlled by three levers worked by one man).

All these movements are got by an arrangement of toothed wheels and pinions, and fitted with friction clutches to ensure no breaking of the teeth should the machine be overloaded or the buckets meet any obstruction.

Fig. 2.

The method of working the machine is to level the earth in front by the machine travelling backwards and forwards over the higher parts until these are level with the lower, then to set a cut by the machine of from five to six inches depth, and travel the machine along the full length of rail and on completion of each cut to lower the bucket ladder another five or six inches for the return cut, keeping the buckets working continuously.

The machine is at present excavating below its base. On a sufficient opening being made to allow the machine to work in the excavation, the machine will be moved on top of the coal. A strip of coal will be removed parallel to the cutting, broad enough to allow the railroad to be laid alongside the cutting, and also sufficient space to deposit the excavated material from the end of the conveyer beyond the railroad. The machine will then excavate the earth above the coal, and deposit beyond the railroad in the space the coal has been cleared from.

As the track of the machine is moved in closer to the bank (which will be about 12 feet at each move, this being the length of the horizontal piece at the bottom of the ladder) it will leave a strip of coal 12 feet broad to be taken away at the back of the machine, with a railroad alongside the coal, and as this strip of coal is removed, the rail-track will be moved up to the coal face again, and by this method the coal can be loaded direct into the cars.

This machine is manufactured by the Lubecker Machine and Manufacturing Company, and was supplied by F. S. Dudgeon, Limited, of London, England, and is the usual A. type machine supplied with the conveyer.

COST COMPARISONS OF ELECTRIC AND HORSE-DRAWN TRUCKS.

Interesting figures are published in the April issue of the Journal of the American Society of Mechanical Engineers with regard to the findings of an investigation into the comparative cost data of electrically equipped trucks and horse drawn vehicles made by W. R. Metz, superintendent of the government office, Washington, D.C., for purposes of ascertaining the desirability of replacing the horse-drawn wagons with electric motor trucks. An abstract of the report is published below:—

In the preliminary investigation figures were obtained on a 2,500-lb. electric truck that had been in service at the Washington naval gun factory for four years. The cost of operation and the saving accomplished were as given in Table 1. A 5-ton electric truck was in use there during the same period. Its cost of operation was about the same as for the 2,500-lb. truck, except that it cost $1.10 for charging per 40-mile radius as compared with 75 cents for the smaller truck. Its total cost of operation, including depreciation and interest, was figured at $2,843.84. It displaced two two-horse wagons, affecting a net saving annually of $2,460.92.

Table 2 gives cost figures for the single-horse vehicles of a large company using horse-drawn wagons and electric and gasoline machines. By adding the items for extra horser and harness, similar totals for two, three and four-horse wagons are found to be $740.52, $1,016.23 and $1,291.94.

In Table 3 are given the operating costs for the same company's electric trucks.

During the fiscal year 1910 the expenses of the stable section of the government printing office were $31,113.58, and those for the delivery section were $17,093.93, making a total of $48,207.51. The figures were slightly higher in 1911. Table 4 itemizes these 1910 costs, and from this table Table 5 is derived, showing the operating cost of one two-horse wagon of 5,000-lb. capacity.

Beginning in November, 1911, electric trucks and carriages of various capacities have been installed, and most of the horses and their equipment have been sold. Table 6 gives costs with the present equipment. The remaining horses are to be replaced, after which the four remaining stablemen will probably be supplanted by two helpers and a laborer, effecting a further reduction of $1,377.20 annually.

From the monthly cost records the operating cost of one 5,000-lb. electric truck is derived and shown in Table 7. One such truck replaces two two-horse wagons, the cost of which, as shown in Table 5, was $6,737.72. The annual saving due to the electric truck is therefore $4,204.39.

Based upon the assumption, in the absence of mileage figures for the horse-drawn wagons, that they averaged 12 miles per day—it being known that the electric trucks average 24 and make twice as many trips as the teams did—Table 8 is derived to show the comparative costs per month and per mile for operating the horse-drawn vehicles and the three sizes of electric trucks.

Table 1.—2,500-Pound Electric Truck.

Cost of truck	$2,230.00		
Labor for charging batteries		$ 46.44	
Charging		16.50	
Acid		18.00	
Rubber jars		15.00	
Batteries (partly renewed)		64.98	
Carbon brushes		1.80	
Repairs		99.96	
1 operator at $2.48 per day		776.24	
2 laborers at $1.92 per day each		1,201.92	
Totals	$2,230.00	$2,240.84	
Depreciation 10 per cent.		223.00	
Interest on investment at 2 per cent.		44.60	
Total cost			$2,508.44

Total mileage per year....3,366
Cost per mile $0.745
This truck displaced 5 horses and carts costing as follows:

5 carts by contract at $1.92 per day	$3,004.80	
5 laborers at $1.92 per day each	$3,004.80	
Total		$6,009.60
Net saving of truck over horses per year		$3,501.16

Table 2.—Horse-Drawn Vehicles.

Investment—		
1 horse	$250.00	
1 vehicle	125.00	
Harness	30.00	
Total	$405.00	
Maintenance and upkeep—		
Depreciation—		
Horse at 20 per cent.	$ 50.00	
Vehicle at 15 per cent.	18.75	
Harness at 15 per cent	4.50	
Interest on $405 at 6 per cent.	24.30	
Total		$ 97.55
Horse upkeep—		
Feed at 47.4 cents × 365 days	$173.01	
Shoeing at 7.5 cents × 365 days	27.38	
Veterinary at 1.1 cents × 365 days	4.02	
Total		204.41
Vehicle expense at 43.4 cents per day	$158.35	
Harness expense	4.50	
Total		162.85
Total expense exclusive of labor and stable		$464.81

Table 3.—Expense of Operating Electric Commercial Vehicles.

Capacity, Lb.	850-1,000	1,500-2,000	2,500-3,000	4,000	7,000
Interest and depreciation (machine less batteries and tires)	$244.50	$306.30	$391.40	$422.94	$470.84
Mechanical and electrical upkeep	67.54	84.15	101.70	110.96	121.42
Tire repairs and renewals	79.28	97.30	155.05	267.60	535.25
Battery repairs, cleaning and renewals	130.50	175.36	219.34	271.54	312.84
Current at 1 cent per kw. hr.	20.00	30.20	40.00	60.00	51.50
Totals	$541.82	$693.31	$907.49	$1,133.04	$1,491.85

Table 4.—Cost Data for Horse-Drawn Vehicles for Year Ending June 30, 1910.

Equipment—	
23 Horses (average per year)	$ 6,900.00
Harness, blankets, etc.	1,350.00
1 Five-ton truck (2-horse)	425.00
7 Large delivery wagons (2-horse at $475 average)	3,325.00
6 Single delivery wagons (1-horse at $275 average)	1,650.00
3 Light mail wagons at $200	600.00
4 Depot wagons (carriages) at $300	1,200.00
2 Coupes, with pole and shafts, at $540	1,080.00
Total	$16,530.00
Cost of operation of stable section—	
Wages of foremen and stablemen	$10,113.59
Wages of drivers	12,666.21
Rent	2,400.00
Feed	3,172.20
Supplies	959.62
Repairs to harness, wagons, etc.	626.86
Shoeing	906.60
Gas and electricity	268.50
Total cost of operation, maintenance and repair	$31,113.58
Depreciation, horses 20 per cent., harness 15 per cent., wagons 10 per cent.	2,410.50
Interest on investment at 2 per cent.	330.60
Total cost, including depreciation and interest on investment	$33,854.68
Cost of operation of delivery section—	
Salaries and wages	$17,085.93
Material and supplies	8.00
Total cost	$17,093.93

Table 5.—Cost per Year of One 2-Horse 5,000-Lb. Wagon.

CONTENTS OF THIS ISSUE.

MONTREAL AND ITS LOST OPPORTUNITIES.

Those of our readers who are at all acquainted with Montreal will appreciate and realize how much to the point is a criticism that Mr. T. H. Mawson, of the University of Liverpool, and who is an acknowledged international authority on the subject of Town Planning, makes regarding the city's lack of appreciation and making the most of their opportunities for a beautiful city. In his recent lecture in Montreal before the Greater Montreal Planning and Housing Association, his remarks as regards any attempts that have been made to make the most of its natural advantages were not by any means very flattering. It is hardly to be expected, in fact, that an observing man could fail to criticize.

Montreal's streets for a city of its size are probably the worst on the continent. While severe winter weather no doubt makes it hard to maintain good roads, nevertheless neither the weather nor the engineers are to blame for their absence, but the Civic Administration itself. It has always seemed impossible to persuade the majority of the aldermen of Montreal to take any kind of a broad-minded view of affairs, or to have pride in the construction and building up of a clean, well-built, beautiful city. Instance of civic lack of appreciation of opportunities and future needs are numerous. One occurred a few years ago in connection with the sale of some property belonging to the Redpath estate. This estate occupied part of the southern flank of the Montreal Mountain and abutted on Mount Royal Park. The purchase of it would have given the city, in addition to acreage, a beautiful driveway and entrance to the park from Sherbrooke Street, which had been long needed and was considered extremely desirable. The land was offered to the city at what those qualified to judge considered a most reasonable figure, and had behind it, we believe, a public-spirited consideration of the city's good. After a great deal of unnecessary delay and hesitancy and opposition on the city's part, the owners became disgusted, withdrew their offer, and it was quickly sold at a higher figure to real estate people, who have since used it for building purposes. A more utter lack of appreciation for the city park system and future good of the absent than that exhibited in the above case could hardly be found.

In his criticism of Montreal, Mr. Mawson stated that he had been in the city many times, and had always been struck with the magnificent opportunities which have been lost. The city has been laid out on the most unimaginative lines, and no cognizance whatever has been taken of its natural contours. This great natural amphitheatre overlooking the river offered opportunities for one of the most magnificent cities in the world. There were few sites which could compare with it.

On the subject of the streets and the steep grades of same, a suggestion which Mr. Mawson made which will appeal to all acquainted with the city's layout was that for the construction of a new and direct highway between Victoria and Dominion Squares. Such a road would do away with the steep traffic conditions encountered on such streets as Windsor, Bleury and Beaver Hall Hill. It is a subject which, now that the Canadian Northern is busy on the planning and construction of terminals and stations across the immediate path of the proposed road, should have been considered and provided for in the general layout beforehand by the Civic Government.

It is sincerely to be hoped that Montreal will shake itself of the lethargy it has shown in the past as regards the beautification of one of our finest cities.

THE LIVINGSTONE CHANNEL.

The opening of navigation of the Great Lakes continues to bring into public prominence the Livingstone Channel in the Detroit River. In last week's issue we spoke of it in connection with the work of the International Joint Commission, and their decision, re a proposed new dyke for maintaining the depth of water upstream from it.

At the present time of writing word has just come to hand of the grounding of a steamer in the channel which seriously threatens any navigation through it. When we consider the enormous traffic through the Detroit River, any threatened interruption naturally affects shipping interests to a very marked extent and the business public as well.

The Livingstone Channel was only formally opened on October 19th of last fall, and apparently the conditions are not yet ideal for traffic through it. Its construction was authorized by the United States Congress in 1907, and four and a half years were occupied in its completion at a total cost of ten million dollars. The channel was cut through practically solid rock for more than six of its thirteen miles of length, and runs in a direct line from above the head of Bois Blanc Island to deep water in Lake Erie.

The preparatory work was begun in the spring of 1908, when the contractors began erecting the cofferdam, which enclosed what is known as the dry-work section, about a mile of the river bed near the upper end of the rock cut. Actual channel digging was begun in the fall of the same year.

Originally constructed with a width of 300 feet, the dry section was completed in November, 1910, but was later widened to 450 feet, and addition being completed in December last, before the river was permitted to fill the enclosed space. Below the dykes for about five miles the channel has a width of 300 feet, while below that point, where the material to be removed was earth, the width is 800 feet. In the dry section the channel has a depth of 23 feet. Throughout the remainder of its length the least depth is 22 feet.

PROPOSED FEDERAL LAW IN REGARD TO THE POLLUTION OF NAVIGABLE STREAMS.

There has recently been appointed at Ottawa a Commission comprised of eighteen members of Parliament for the purpose of enquiring into the pollution of Canadian sources of water supply. The appointments are the result of the introduction for a second reading of Mr. Bradbury's Bill to prevent pollution of streams as above.

That the Government should take means to be advised on the subject, and to frame legislation in connection with same, is admittedly a most desirable step. It has been brought out in the past on several occasions that even the water of our Great Lakes, which ordinarily one would not consider on account of their bulk to be in any probable danger of general pollution for years to come, contain considerable amounts of chlorine at far distant points from sources of contamination. Analyses show, for instance, that the amount of chlorine in the west end of Lake Ontario has increased two and a half times in thirty years, while in the easterly end the amount of chlorine has doubled in twenty years. This increase in chlorine indicates sewage pollution, which, if not stopped or minimized, will in time render even our Great Lakes unsafe for use as a public water supply.

Consider the official figures, which show that the toll of death from typhoid in Canada is 35.5 per 100,000 of the population. In Germany it is only 7.6 and in England 11.2. Ottawa and Winnipeg are cities whose populations have suffered severely from epidemics of typhoid, due to the pollution of the Ottawa and Red Rivers, respectively. What they have gone through, other towns will have to combat with, unless steps are taken immediately to fortify with federal aid the sometimes inadequate and careless attempts of local municipalities to protect their water supply from dangerous contamination.

The ultimate aim of the Government in appointing the Commission is most admirable, but we cannot see that there is anything to be commended in their way of going about the work before them. The work in connection with this Commission could have been much more efficiently and rapidly carried through by the appointment of a much smaller commission composed of competent engineers and medical health officers rather than by an unwieldy body of non-engineering parliamentarians, whose appointment leaves a very probable opening for misunderstandings and mis-translations of engineering opinions and data given them. We cannot see any possible excuse, if efficiency is desired for such appointments. While this parliamentarian committee may wade through investigation to some beneficial and corrective legislation, they are, nevertheless, both on account of bulk of numbers and lack of training on the subject, unwieldy, slow and unfitted for the work.

It is time the Government was made to wake up to the fact that when reports and investigations are wanted on subjects relating to science, any ignoring of the professions concerned is dangerous to them, politically. The public should be made to understand the foolishness and unbusiness-like method of eighteen unscientific and wholly unqualified Parliamentarians enquiring into a matter which could be much better done by those acquainted with the engineering and scientific sides of the problems involved.

MONTREAL TRANSPORTATION PROBLEM

It begins to look as though Montreal would shortly find an exit from the tramways problem which has been worrying it so long. Two announcements have recently been made, either of which contains the elements of relief.

Recently the president of the Tramways Company approached the city with a tentative proposal. Later a conference was held at which something in the nature of a definite plan was placed before the representatives of the city. In this was outlined a scheme for the relief of congestion both immediate and future. Certain streets were asked for, for the extension of the company's lines. The programme was not unlike that proposed by Mr. Duncan McDonald. The Tramways president does not appear to have asked anything unreasonable. His proposal called for practically only one new line of any considerable extent, which line ran through a section of the city not now adequately served and upon streets to which there could be no particular objection. Other proposals were such as have been approved by the city council, such as making the stops less frequent. In the down town section it was proposed to use Victoria Square as a stopping point for certain cars instead of continuing

these through the congested district. Altogether the proposals seemed of a reasonable nature, and unless there is more behind them which has not yet been made public, there would not seem to be any good reason why the city should not meet the company in the matter. President Robert promised to put on a very much larger number of cars and to construct a roadbed of a superior character. Up to the present the city authorities do not appear to have given any very definite indications of how they regard the proposals.

Shortly after President Robert made his proposals to the city, fuller details concerning the Canadian Auto Bus Company appeared. It may be recalled that this company was organized some time ago to carry on an auto bus service in the city of Montreal. The company made certain proposals to the city, in which the city was to be a holder of a very considerable number of the shares of the company, this being the company's reward to the city, so it was thought at the time, for granting an exclusive franchise for ten years on certain streets. Objection to the arrangement between the city and the company was offered by a number of citizens and it it quite likely that the question is still before the courts.

At first, the names connected with the company were not those of well-known financiers, and a certain amount of doubt concerning the seriousness of the project was entertained. Within the past week, however, an announcement has been made to the effect that Mr. H. S. Holt, president of the Montreal Light, Heat and Power Company; D. Lorne McGibbon, president of the Canadian Consolidated Rubber Company; F. L. Wanklyn, general executive assistant of the Canadian Pacific Railway; are all mentioned in connection with the concern.

The capital of the company is $10,000,000, and the Canadian group, together with the English group, which has become interested in the concern, have already subscribed $1,500,000. The concern has a Federal charter which permits it to operate in any city in Canada.

The interesting features in connection with the above directorate is the mention of a number of names which have been spoken of as greatly opposed to projects of the president of the Montreal Tramways Company. It is generally considered on the Street that the Auto Bus Company will be strongly opposed to the Tramways Company. The franchise from the city of Montreal dates from last August, and according to the terms the company is obliged to give a five-minute service. It has been stated, however, that instead of a five-minute service the concern will give one which will be twice as frequent. The cars will be of the single deck variety on all steep grades, but it is not impossible that the double-deck variety will be employed on the leveller grades. The capacity will be from 28 to 38 people and the franchise insists that there shall be no strap hangers but that all passengers shall be provided with seats. The fares will be five cents, straight, and transfers to all lines of the company.

The city of Montreal has now spread clean across the island and extends a long distance east and west so that the auto busses will not be confined to a limited territory because of lack of ability on the part of the city to extend permission. The franchise, of course, only covers certain streets. Altogether it is expected that fifty auto busses will be running here by mid-summer, or shortly thereafter. There seems to be some disposition on the part of the city officials to delay action in the matter of the Tramways Company until the effect of the establishment of the auto bus service is felt. In the winter time the heating of the cars will be sufficiently accomplished through the exhaust.

AN INTERESTING HYDRAULIC INVESTIGATION.

In the fall of 1912 an investigation of the power possibilities for the town of Picton, Ontario, was made on the Mountain Lake power site by Mr. H. G. Acres, hydraulic engineer to the Hydro Electric Power Commission of Ontario. The report of the investigation appears in the last report of the Commission and is given herewith:

The Mountain Lake power site is owned by F. S. Wilson, Esq., of the J. C. Wilson Co., of Glenora, and hydraulic power is produced for the purpose of operating a machine shop, foundry and grist mill. The machine shop runs practically continuously six days a week, eleven hours a day, and uses about 28 h.p., while the grist mill and a storehouse, which use the greater amount of power, operate intermittently, being frequently closed for a week or more at a time.

The gross operating head is between 165 and 170 feet, the mean effective head being probably not less than 160 feet.

Mountain Lake, Approach Channel to Weir.

Although there is sufficient turbine capacity installed to generate about 130 h.p. it is probable that 75 h.p. would amply cover the average annual demand. On a basis of 66 hours a week operation the annual expenditure of energy would therefore, be about 257,400 h.p. hours. If this amount of energy were expended uniformly and continuously over the whole year of 365 days, it would be equivalent to about 30 h.p. continuous 24 hour power. With the turbine installation at present existing, this amount of power would be produced by a continuous uniform outflow from the lake of about 3 cu. ft. per second. Allowing 2 cu. ft. per second for leakage, the total discharge required would, therefore, be 5 second feet.

Five second feet flowing for one year would deliver a total volume of 157,680,000 cu. ft. of water. The area of the lake with its tributary water-shed could be reasonably taken at 600 acres, and assuming 12 inches of precipitation available for power purposes, the total surface inflow into Mountain Lake would amount to 26,136,000 cu. ft. per annum. Subtracting this amount from the total quantity above specified as being delivered to the wheels, leaves a remainder of 131,544,000 cu. ft., which is, therefore, the annual volume of delivery from underground sources. This volume of underground supply is equivalent to continuous uniform flow of 4.2 cu. ft. per second, which, on the basis of the above assumptions, would be the average volume of discharge from the underground supply.

The above figures constitute practically all the information that could be derived from the data in existence when the investigation of the power site first came up for consideration.

Owing to the existence of a market for power in the town of Picton, about 4 miles from the power site, it was considered necessary to investigate conditions in greater detail in order to ascertain definitely whether or not there existed in this power site a sufficient capacity to supply the requirements of the town, and in this connection the first step was to devise some means of accurately measuring the discharge out of the lake.

The lake is located at the top of a precipitous hill on the south shore of Picton Bay, the difference in level between the bay and the lake being ordinarily about 175 feet, the shores of the two bodies of water being not more than 600 feet apart. The water is carried from the lake through a small head gate and several hundred feet of riveted steel pipe to which the various wheels are connected at the foot of the hill. Owing to the leakage in the pipe and the absence of data relating to the volume of discharge through the wheels, it was necessary to use some other means of measuring the discharge from the lake. It was f und upon examination that the only practical means of doing this was to excavate a channel about 150 feet long from the lake into the bed of a small brook, which was evidently at one time the lake's natural outlet. This channel was excavated 12 ft. wide and to an average depth of 2 ft., and at the head of it was placed a sharp crested weir having a clear width of 12.01 feet. With the weir so placed it was possible to get the maximum head of 11½ inches on the crest, which was equivalent to a total discharge of about 37.6 cu. ft. per second. Discharge readings were taken on this weir at intervals of 15 minutes between 3.15 p.m. on Sept. 7th and 3.15 a.m. on Sept. 8, the work having been done on Sunday in order that the mills could be closed down and the head gate tightly closed. The readings taken over this 12 hour interval showed a total volume of 1,450,202 cu. ft. and it was also observed that during this 12 hour period the surface of the lake had dropped 1.56 inches. This drop in water level indicated that the measured outflow was composed of the underground discharge plus a volume of water corresponding to a drop in lake level of 1.56 inches.

During the course of the investigation an accurate stadia survey was made of the lake, and the area was found to be 9,352,000 sq. ft., or about 215 acres, so that 1.56 inches drawn off this area would mean a total volume of 1,215,760 cu. ft. which was discharged over the weir. As above mentioned, the discharge over the weir amounted to 1,450,202 cu. ft., so that the difference between these two totals, which amounts to 234,442 cu. ft., is a measure of the volume of supply from underground sources. This volume of flow delivered for a period of 12 hours is equivalent to a continuous discharge of about 5 cu. ft. per second, which is one of the results which the experiment was designed to supply.

At the conclusion of the above mentioned 12 hour period, the discharge was entirely shut off and it was found that for a subsequent 12 hour period the lake showed no tendency to fill up, the gauge readings being practically the same at the end of the second 12 hour period as at the beginning. In this connection, it is to be noted that the supply from which the lake was to be refilled had been ascertained to be 5 cu. ft. per second. With this volume of inflow it would require about 80.5 hours for the lake to fill to the original level, which would be at the rate of slightly less than ¼-in. every 12 hours. The slow rate of refilling, therefore, accounts to a certain extent for the absence of appreciable variation in level during the second 12 hour period,' but sufficient evidence was obtained in any event to prove that the recuperative capacity of the lake is very small.

From the above, therefore, it seems evident that while the lake appears to be supplied by springs having a very large volume of discharge, the dependable power capacity would not be more than 75 h.p., and that while the site is eminently suited to the purpose for which it is now utilized, it cannot be considered an adequate source of power for general industrial purposes.

It is, of course, possible that if the lake level could be materially lowered a corresponding increase of flow from the springs could be anticipated. The lowering of the lake level would tend to reduce the power capacity through the reduction in head, and this would, to a certain extent, effect the tendency to augment the power capacity through the result of the increase in flow, so that there would be what might be termed a critical head at which the maximum power capacity would be realized. This critical head could, of course, only be ascertained by very expensive experimental procedure. As an example of what the result might be, it might be assumed that by lowering the lake 20 feet the discharge from the springs might be tripled, so that there would be a discharge of 15 sec. ft. operating under a head of 145 feet. This would produce about 198 mechanical horse power. It would seem, therefore, that under no conditions would the site have sufficient power capacity to make it an attractive commercial proposition.

While the work preparatory to the experiment was being done the records were kept of variations of lake level. During the first week of operations, when the machine shop only was running, the water level remained practically constant, while during the second week when the machine shop and grist mill were both running, the water level dropped about two inches, notwithstanding the fact that heavy rains occurred during that interval. During the second week of the observations, therefore, the power required to run the mills absorbed about 1,500,000 cu. ft. from storage in addition to the normal inflow from the springs, plus the precipitation during that interval. This affords additional evidence of the small capacity of the source of underground supply.

TENSILE TESTS OF CONCRETE.

A series of tests on concrete specimens measuring 18in. long by 6in. square has recently been made in the engineering laboratory at Cornell University.

The specimens were of three different mixtures, the first a 1:2:4 mixture containing limestone crushed to pass a 1½-in. ring, the second a 1:2:4 mixture containing sandstone, crushed to pass a 2½-in. ring, and the third a 1:2½:5 mixture containing crushed sandstone similar to that of the second mixture.

In six tests the 1:2:4 limestone concrete showed an average tensile strength of 278lb. per square inch, the highest being 308lb. per square inch, and the lowest 253lb. per square inch.

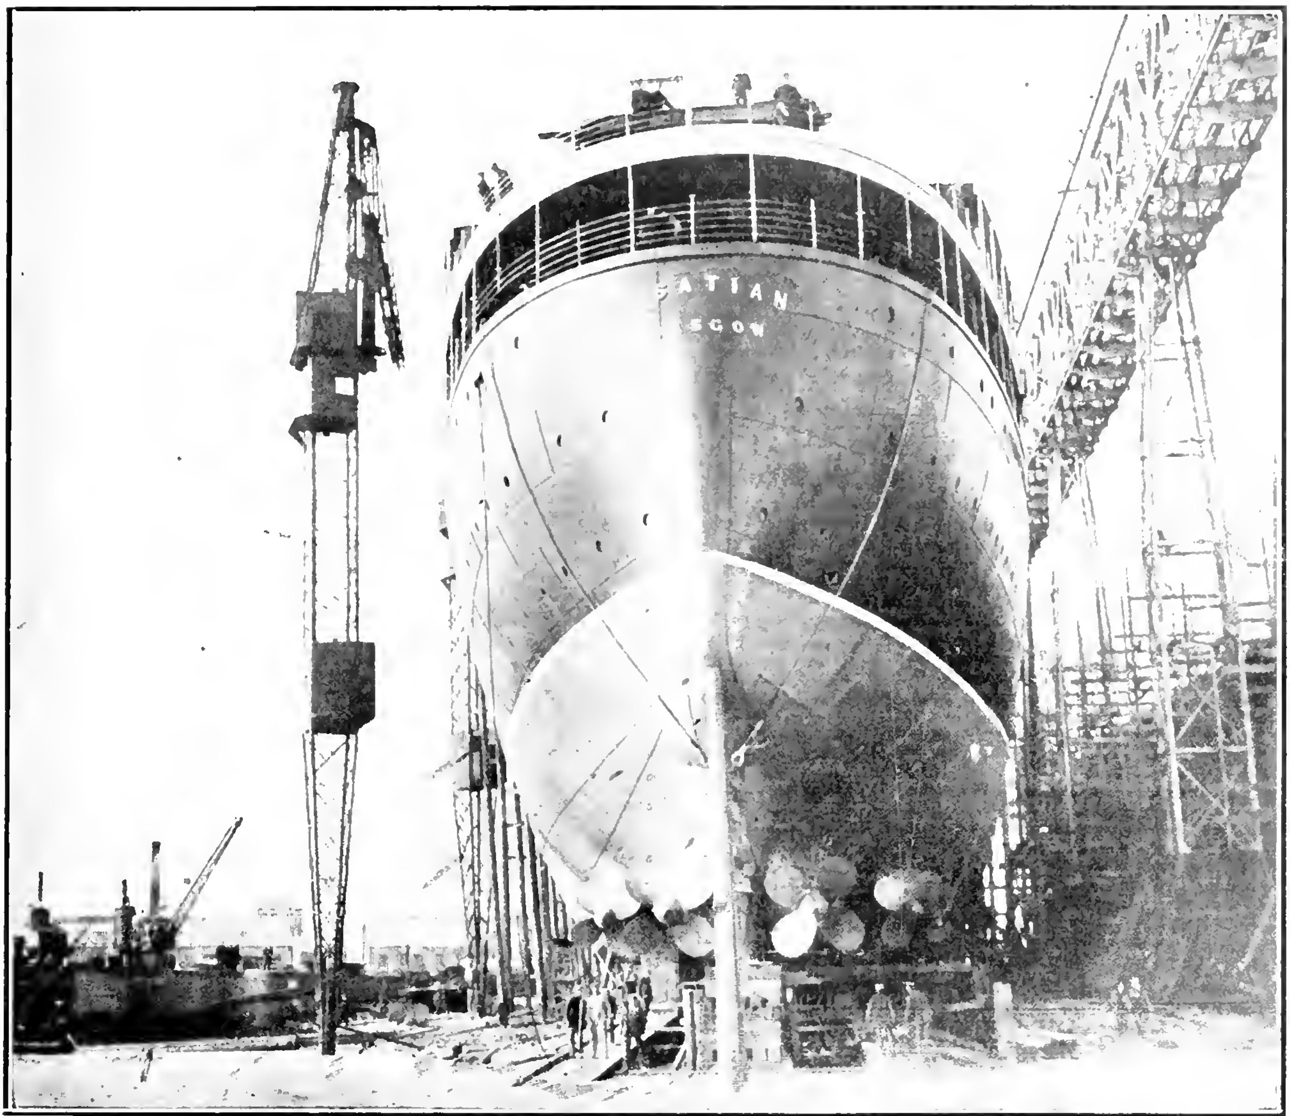
In nine tests, the 1:2:4 sandstone concrete showed an average tensile strength of 150lb. per square inch, the highest being 178lb. per square inch, and the lowest 128lb. per square inch.

In nine tests, the 1:2½:5 sandstone concrete showed an average tensile strength of 129lb. per square inch, the highest being 179lb. per square inch, and the lowest being 97lb. per square inch.

It is worthy of note that in many instances particles of sandstone were split in two in the plane of the fracture instead of breaking the bond with the mortar; this was particularly so in the case of the red sandstone, and illustrates the importance attaching to the selection of aggregates for employment in concrete work.

QUADRUPLE-SCREW TURBINE ALLAN LINER "ALSATIAN."

The Allans have been identified with the Canadian mail, passenger, and emigrant service for over ninety years. The line was originated by Captain Alexander Allan, a ship-owner-mariner of Glasgow, with a brigantine, named the "Hero," of 175 tons, her first duty being to carry stores to Wellington's army in the Peninsula. The service to Quebec was inaugurated by the "Jean" of corresponding size to the "Hero," in 1819, and was continued with a fleet of sailing ships of from 300 to 400 tons. Later, iron was adopted, and by 1845 the tonnage of the ships had risen to 710 tons. The limited the dimensions of steamers sailing up [illegible]rence. But improvements have been made within [illegible] few years, with the result that steamers of 16,000 and [illegible] tons now find no difficulty in reaching Montreal. The [illegible] fleet of the Allan Line is now represented by a quarter of [illegible] million tons gross, and there can be no doubt that the Allans not only in connection with their steamship service, but in other respects, have done much to develop Canada to that state of prosperity which in recent years has enabled the extension of railway lines to be profitably undertaken, and to stimulate the utilization of the natural resources of the enormous tract of rich grain growing soil. Internal development and attractive emigrant services across the ocean act



Stern View, Showing Propellers.

first steamer was placed in the service in 1854, to carry out the mail contract with the Canadian government. The steamers by 1858 had reached a tonnage of over 3,000 tons, with machinery of about 1,800 indicated horse-power, the service speed being 11 knots. Two notable ships on the list are the "Victorian" and the "Virginian," the first ships to trade in the Atlantic fitted with Parsons turbines. The advance in size and speed is the more remarkable as the condition of the channel between Quebec and Montreal greatly

and re-act upon each other, and thus, with the enterprise of steamship owners and of the Canadian railway companies, the Dominion must advance very rapidly. For his services to Canadian commerce, Mr. Hugh Allan was knighted by Queen Victoria in 1871. His son, Mr. H. Montagu Allan, was knighted by King Edward in 1904. A younger generation of the family now carry on the business of the founders of the line with marked success, Mr. Hugh A. Allan, in London, being the chairman of the company.

The first of the two new ships to be launched is named the "Alsatian," and has been constructed by Messrs. William Beardmore and Company, Limited. A sister ship, the "Cal-

---

* Abstract of portion of a description of "Alsatian" in Engineering.

garian," is being constructed by the Fairfield Shipbuilding and Engineering Company, Limited. The launch of the "Alsatian" recently was an unqualified success, and the occasion is of interest, as the vessel is the first to be launched by Mr. A. J. Campbell, who has taken up the management of the works, after having completed the organization of the Spanish naval establishments at Ferrol and Cartagena, as shipyard manager of the Sociedad Espanola de Construccion Naval.

The following are the principal particulars of the "Alsatian," which was designed, and was built from specifications, by Mr. A. M. Gordon, the naval architect of the Allan Line:

Length on L.W.L.	600 ft.
Length between perpendiculars	570 ft.
Breadth, moulded	72 ft.
Depth, moulded, to "D" deck	54 ft.
Gross tonnage (about)	18,000
Draught fully loaded	28 ft. 6 in.
Speed on trial, fully loaded	19 knots
S.H.P. on trial (about)	20,000
Speed on service	18 knots
Number of decks	8
Number of water-tight bulkheads	11
Number of first-class passengers, about	200
Number of second-class passengers, about	500
Number of third-class passengers, about	1,000
Number of officers and crew, etc.	500

A notable feature of the ship is the adoption of the cruiser stern. This arrangement confers several advantages. In the first place it is possible to get a greater displacement on a given length over-all, with corresponding increase in dead-weight, or, if the displacement be not increased, the lines may be fined down, so that the ship is more easily driven, with corresponding reduction in engine power. In the second place, the fuller water lines aft which are permissible with this type of stern ensure greater stability, especially at the deeper draughts. In the third place, it is probable that this form of stern tends to reduce the vibration due to propellers. This reduction in vibration is further ensured by the placing of the steering gear low down in the ship, immediately over the rudder-head, so that the weights in the after part are more directly water-borne than where the steering gear is placed on the poop-deck or immediately under it, with an overhanging counter. It is further claimed that the cruiser form of stern will make the ship more comfortable with a following sea, as there will be less tendency for her to "slam" on the waves. This form of stern also increases the deck space aft for the accommodation of passengers. The balanced rudder fitted with this type of stern considerably improves the manœuvring powers of the vessel, and being entirely immersed and protected by the long overhang aft, it is less liable to damage from ice, floating wreckage, or other obstructions, especially when the vessel is going astern. To some, however, the appearance of the ship aft may not appear so attractive as with the older form of stern with a counter of graceful lines, but this is largely due to the training of the eye.

The vessel is fitted with a double bottom all fore and aft, which is carried to the upper portion of the bilge—much higher than in some recent passenger ships. Bilge-keels of the Admiralty type are fitted for about half of the vessel's length amidships, to minimize rolling in heavy weather. The shell for about 80 feet from the stern has been doubled for a considerable extent both above and below the water-line, with a view to protecting the hull from ice, and the framing has also been specially strengthened for this purpose. The frame-spacing for the major portion of the length is 3 feet, being reduced gradually at the ends to 2 feet in the forward and after peaks. Hydraulic riveting was adopted for a considerable portion of the length amidships on the upper portion of the shell and stringers, where tensile and compressive stresses are likely to become greatest. Another feature in connection with this vessel is that no expansion joints are fitted in the boat or promenade decks forming the upper structure; these have been specially strengthened with a view to taking their portion of the stresses.

The vessel is designed so that she will have a positive G.M. of not less than 3 inches when fully equipped, in light condition; thus she may be moved in dock without the excessive use of water ballast. The vessel has been subdivided by eleven water-tight bulkheads, built up generally of plating 17/40 inch at their lowest part and 10/40 inch at their upper part, the average thickness being about 15/40 inch. The stiffeners of the lower portion consist of bulb angles 10 in. by 3½ in. by 22/40 in., and the upper portion of angles 4 in. by 3 in. by 12/40 in., with additional webs where required locally. All the water-tight bulkheads are carried up to "E" deck, and are therefore 9 feet above the maximum load line at the lowest point of the deck. Several of them, however, are carried to "D" deck, which is 8 feet higher. In addition to this, "F" deck is made water-tight at the forward and after ends of the vessel, beyond the machinery spaces. It is therefore calculated that the vessel will float with any four adjoining compartments open to the sea. Hitherto the Board of Trade have only required a vessel to be capable of remaining afloat with any two adjacent compartments open to the sea, so as to enable her to claim a reduction on the number of boats and other life-saving appliances to be carried; but in this vessel the aim has been to ensure her remaining afloat with four adjacent compartments open to the sea, which is far in excess of Board of Trade requirements, whilst the boats and life-saving appliances are also sufficient for every person on board, in accordance with the latest regulations. A further element of safety in this vessel is that all the vertical and horizontal sliding watertight doors which it was found necessary to fit in the watertight bulkheads below "E" deck are actuated hydraulically from the bridge on the Stone-Lloyd system, and provision is also made for working them independently at the doors or from "E" deck.

The vessel has eight decks, so constructed that they ensure the passengers of the three classes comfortable and pleasant quarters.

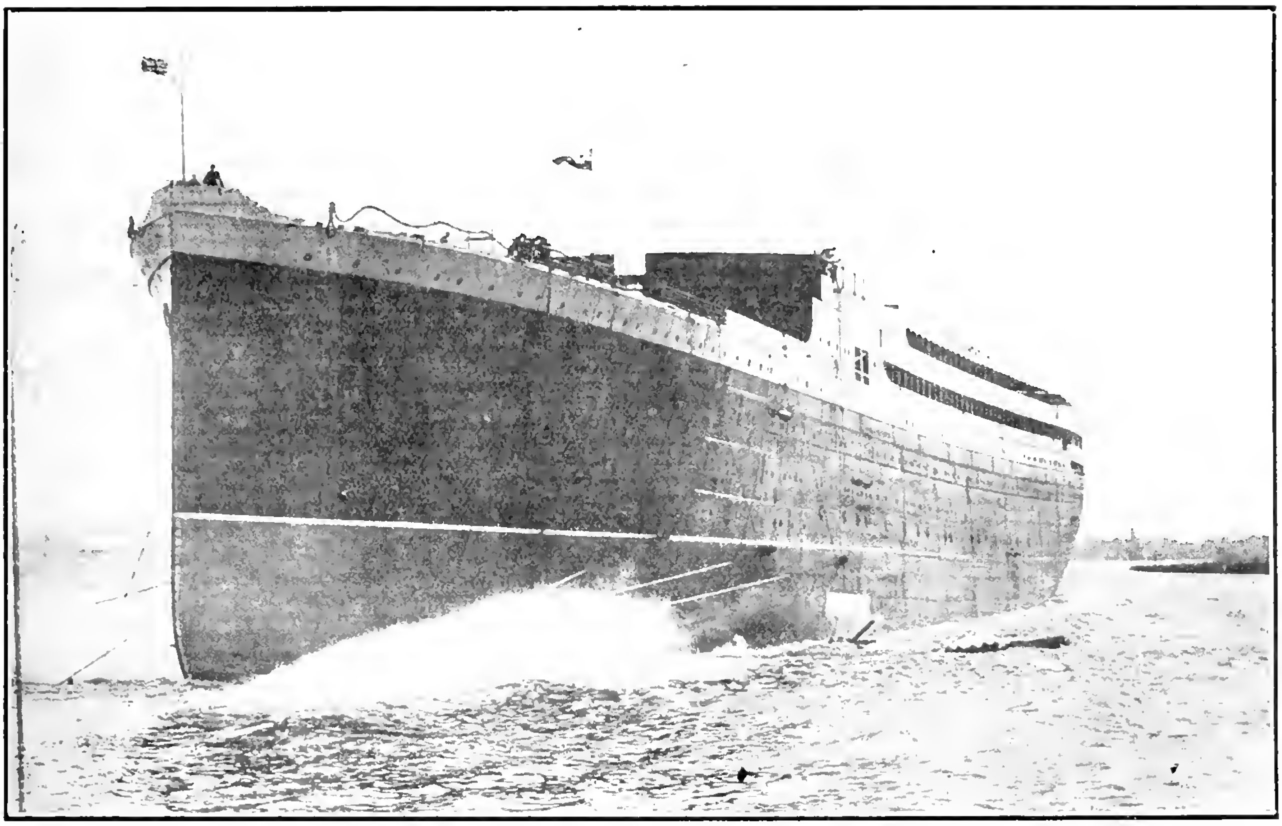
The gear for working the anchors consists of two separate and independent engines, each driving one cable-holder and one warping capstan, by Messrs. Napier Brothers, Glasgow. In addition there are four independent steam warping capstans, two on each side of the vessel. The engine for each capstan is placed in a separate house, and connected by shafting to the capstan, which is outside of it. The steering gear is by Messrs. Brown Brothers, and is of their latest steam steering-tiller type, with stand-by steering gear, the whole controlled by means of tele-motor gear.

There are ten steam-winches for working cargo, six of which are 8 in. by 12 in. (double), and four are 8 in. by 12 in. (single).

There are five electric lifts, one passenger lift, two for stores, and two for mails and baggage.

The main electrical generating plant consists of three steam-turbine-driven sets constructed by the British Westinghouse Electrical Company, each capable of giving a continuous output of 250 kw. at a pressure of 2 × 110 volts when running at 3,000 revolutions per minute. The turbines of the main generating sets are of the Westinghouse impulse type, the normal steam pressure being 150 lb. per sq. in.,

exhausting against a back pressure of 12 lb. gauge. The dynamos are of special construction, and are fitted with slip-rings on the shaft, to which tappings are taken from the armature windings, thence through brushes to the auto-transformers or balance-coils, the middle or neutral point of the balance-point constituting the mid-point of the direct-current circuit. A small emergency turbo-generator is also provided and placed in a separate compartment on the lower promenade "C" deck well above the load water-line of the vessel. This emergency set is also being manufactured by the British Westinghouse Company, and is of 20 kw. capacity at 110 volts. The main generators are placed on an elevated platform on the port side of the engine-room aft, and the main switchboard abaft of the machines on the bulkhead. The switchboard contains the three dynamo panels fitted with automatic circuits of massive design; voltmeters and ammeters of the moving coil type and shunt-regulators for each



Ship After Launching.

dynamo, there being in all thirty circuit-breakers and fourteen switches and fuses.

A special feature of the installation is the three-wire system, which, we believe, is now fitted for the first time on a large passenger ship. All heavy-power circuits are fed direct from the main switchboard at 220 volts pressure, the lighter and smaller motors being supplied from each side of the three-wire supply at 110 volts. From the switchboard heavy lead-covered cables are run on the port and starboard side to auxiliary switchboards placed in different compartments, and interconnected by heavy cables through circuit-breakers, forming complete ring mains round the ship, these being so arranged that in the event of a failure on any cable, a full supply is still obtained through the opposite feeders. Special precaution against heating has been made by carrying all feeders clear of the engine and boiler-room on the deck above these compartments. The total number of lamps installed throughout the ship is about 3,000, all of these being of the metal-filament type. Cables are also run from the main switchboard to the emergency dynamo, and for supplying a separate emergency circuit, a change-over switch being provided so that in case of accident a sufficient number of lamps can be kept lighted in the engine-rooms, boiler-rooms, and passenger accommodation, also on the boat deck should the main dynamos be shut down. Power is also available from this emergency dynamo for working the wireless installation and navigation lights.

The fittings in the public rooms and state-rooms are in keeping with the scheme of decoration, which is Jacobean. The domes of the lounge, smoke-room, and first-class entrances are arranged with concealed lamps above the colored glass, giving a pleasing effect. Electric clocks of the "Magneta" type are placed in the public rooms, entrances and chart-room, and all are controlled by a master clock. Pearson's automatic fire alarms are fitted throughout the vessel, with an indicator in the navigating-room. Thermostats, or heat detectors, are fixed in the different compartments. These can be set so as to give an alarm at a rise of 15 deg. Fahr., and can be limited for compensation to any predetermined temperature; means are also provided to allow each circuit to be tested for continuity by pressing a button at the indicator. In addition to the above there is a very complete system of fire alarm pushes or bells in corridors, etc., these being connected to indicators in the engine-room and navigating-bridge. Telephone instruments are fitted throughout the suite and special state-rooms are connected through a central exchange situated on the main deck. There is also a system of intercommunication telephones between the officers' cabins, and a similar system in the stewards' department, all of the Sterling Company's make.

For the ventilation of the ship an elaborate system of Ashwell and Nesbit's hot and cold air apparatus is fitted, the whole of the fans for this installation being electrically driven. Forty-six motors are used, which require over 150 horse-power.

For the navigation of the ship Graham's loud-speaking telephones are adopted on the navigating-bridge, communicating between forecastle, crow's-nest, docking bridge aft and chief engineer, Marconi room and engine-room and bow. A complete system of submarine signalling apparatus is arranged in the ship, and also a semaphore with Morse flashing-lamp and keys on a platform above the bridge. There is a navigation-light indicator of McGeoch's new pattern for masthead lights, bow lights, anchor and stern lamps.

As regards the electric appliances in the machinery department of the ship, there are four large forced-draught Howden-Laurence Scott combination fans for boiler-rooms, and twelve ventilating fans for stokeholds and engine-rooms, the total horse-power for these being 250. The three turbine lifting and turning motors have a total capacity of 15 horse-power.

In galleys, electrical power is used for the bakery machine, cooking-ovens, and there are motor-driven spits, knive-cleaners, dish-washers, potato-peelers, and freezing-machines, and a large number of electric hot plates throughout the dining-saloons and bars for keeping food and liquids warm during service; this gear requires about 60 horse-power.

The gymnasium is equipped with motor-driven appliances, consisting of one frictional machine, one Seiste's machine, and three horse exercise machines. Curling-tong heaters and fans are fitted in first-class cabins, also wing fans in the public rooms. A motor-driven printing-machine is also placed in the printing-room. The barbers' shops are provided with the latest type of electrically driven hair-brushes, hair-dyers, and massage apparatus; each machine is fed from a socket placed in a convenient position to the chair, no overhead shafting being required.

The steam whistle is the Willett Bruce pattern, and is worked by a small motor and solenoid enclosed in a water-tight case placed in a convenient position near the whistle. Provision is made for blowing by hand-cord in the ordinary way, and the whistle can be operated by the three switches placed port, starboard, and amidships on the captain's bridge, these are so arranged that either "time control" or "signal control" can be made.

The propelling machinery consists of Parsons' compound steam-turbines arranged in series on four shafts, and including one high-pressure, one intermediate, and two low-pressure turbines. Two astern turbines, each with impulse and reaction blading, are incorporated with the low-pressure turbines, which latter drive the inner lines of shafting. These, therefore, are alone used for manœuvring. Steam from the boilers may pass direct to each turbine, and by a suitable arrangement of pipes and valves, any shaft may be operated independently of the others; but normally the steam will pass in sequence through high, intermediate, and both low-pressure turbines. With this arrangement of machinery, better economy is expected than with the usual four-shaft parallel arrangement.

The turbine casings are of cast iron, and the drums, dummies, spindle, wheels, and shafting are of forged steel made at the Parkhead Works of the builders. Forced lubrication is fitted throughout for the main bearings, adjusting-blocks, and plummer blocks, and the arrangements include four Weir's lubricating oil-pumps, two Carruthers' water service pumps, with the necessary oil-coolers, drain, and reserve-tanks.

The condensing plant is fitted in a separate water-tight compartment immediately aft of the engine-room, and consists of two main condensers of the "Uniflux" type, in conjunction with two dual air-pumps, together capable of carrying and maintaining a high vacuum even in summer, when the temperature of sea-water approaches 75 deg. Fahr. Four centrifugal circulating-pumps are provided for supplying the necessary water to the condensers. The air-pumps discharge to filters of the gravitation type, through which the feed-water flows to large float-control tanks. These control-tanks are arranged about the middle line of the vessel, and suctions are provided for the main auxiliary feed pumps. A large feed-heater of the surface type takes all the exhaust steam from the auxiliary machinery, including the turbine-driven electric generators, and is drained to the float-tanks through the filter. Any surplus exhaust steam may be passed to the turbines. With this utilization of the exhaust steam for heating the feed-water for the boilers great economy in working is expected. Other auxiliaries include pumps for bilge, sanitary, ballast, hot and cold fresh water, hot and cold salt water, and ash-ejector purposes. It should be noted that the sanitary pumps are of the rotary type, driven by electric motors, thus eliminating noise and shocks.

Steam at a working pressure of 200 lb. per sq. in. is supplied by six double-ended and four single-ended boilers of the cylindrical type, working under Howden's system of forced draught, and arranged in two compartments. There are four forced-draught fans, placed on deck above the boilers, and driven by electric motors. Ash-ejectors and ash-hoists are fitted in each compartment, and special arrangements have been made for ventilation of boiler-rooms by electric fans of the pressure type.

The vessel, boilers, and machinery have been built under special survey to British Corporation Rules to enable her to class B.S. with that society, and she will also comply with latest Board of Trade requirements and Canadian immigration laws.

TEST TO DESTRUCTION OF BRICK PIERS FOUR FEET SQUARE AND TWELVE FEET HIGH.

The testing of two brick piers of unusual size is described by Maj. J. E. Howard, Engineer Physicist, Bureau of Standards, in a paper before the National Brick Manufacturers' Association. We have redrawn the diagram showing the test results and with it publish here the portion of the paper relating specifically to the tests. The piers were about 4 ft. square by 12 ft. high, weighing a little over 13 tons each. They were built of common, hard burnt, wire cut building brick from one of the yards of Messrs. Booth & Flinn, Pittsburg. One pier was laid in 1:1 cement mortar, the other in 1:3 lime mortar.

The brick were selected with a view of laying a pier which would display a crushing strength of about 3,000 lbs. per square inch when laid in cement mortar, provided this

Table I.

Pier laid in	Dimensions. Height.	Cross-section.		Sectional area, sq. ins.	Average thickness of joints.	First crack. Total lbs.	Total lbs.	Ultimate strength. Lbs. per sq. in.
cement mortar	12 ft.	47.5 ins.	47.5 ins.	2,256	5-16 ins.	4,737,000	6,580,000	2,917
lime mortar	12 ft.	47.5 ins.	47.5 ins.	2,256	5-16 ins.	676,800	1,710,000	757

pier of nearly 190 cu. ft. volume had a strength per square inch of cross sectional area proportional to one of 8 cu. ft. volume. The pier actually displayed an ultimate strength of 2,917 lbs. per square inch, indicating substantially the same strength in each size. Similarly the pier which was laid in lime mortar was expected to have an ultimate strength somewhat less than 900 lbs. per square inch. It failed at 757 lbs. per square inch.

Owing to their great size the piers were built in the testing machine, where they seasoned until the time of testing. The test of the cement mortar pier was completed when four weeks and three days old. Ten gauged lengths in all of 20 ins. length each were established on the four sides, the extremities of which were defined by small metal plugs cemented in the bricks. As loads were applied and advanced the compression of the pier was measured on these 20-in. lengths by means of a strain gauge, in practically the same manner as thermal effects on cement filled brick pavements are being observed by means of that instrument. The compression of the lime mortar pier was measured when it was 25 days old.

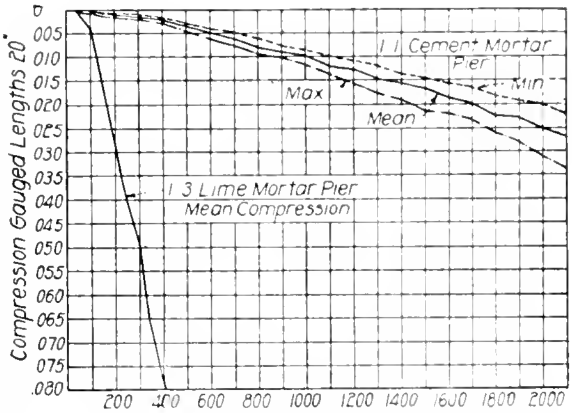


Fig. 1.—Curves Showing Relative Compressibility of Brick Laid in Cement and Brick.

The results of the tests were as shown by Table I.

In failing, along the middle of their heights, the sides opened laterally. Frictional resistance at the ends, between the brickwork and the platforms of the testing machine, strengthened the piers against lateral deformation and probably influenced the pyramidal shapes assumed after rupture. The manner of failure of these large piers was the same as that witnessed in piers of smaller dimensions.

Diagrams are presented to illustrate the behavior of these piers during test and at their ultimate strength. Figure 1 shows the compression curves of the two piers as loads were successively applied. The pronounced difference is in their rate of compressibility is well indicated. This difference is, of course, due to the difference in the mortars used. These curves represent the total compression of the brickwork, which in the case of the lime mortar pier was chiefly permanent set. But that of the cement mortar pier at 1,000 lbs. load was about one-third permanent set and two-thirds elastic compression, or, stated differently, the cement mortar pier would recover about two-thirds of the observed compression upon release of load.

Three curves are given for the cement mortar pier, one representing the mean compression, one representing the minimum compression of the several gauged lengths and one gauged length which displayed the maximum compression. Since the ends of the pier were in contact with and were moved by the rigid platforms of the testing machine this difference in the amount of compression on the several gauged lengths, which were established along the middle of the height of the pier, represents unequal compression locally, and would occasion bending stresses in the bricks and lead to the formation of transverse fractures.

HYDRO-ELECTRIC POSSIBILITIES OF THE MAITLAND RIVER, ONTARIO.

In June of 1912, a report on the power possibilities of the Maitland River was made to the Hydro-Electric Commission of Ontario by Mr. H. G. Acres, hydraulic engineer to the commission. This report, which is incorporated in the last annual report of the commission, just published, gives a considerable amount of data regarding the hydrology of the stream, together with an analysis of the possibilities of commercial development. The report is given herewith in full:

The natural source of power for the county of Huron is the Maitland River, which rises on the height of land between Lake Erie and Georgian Bay, and flows into Lake Huron through the town of Goderich. The watershed of this river is about 950 square miles in extent, and is largely drained and deforested. As a result, the natural flow characteristics have been destroyed, and the watershed of the Maitland River, in common with the watersheds of other rivers in the southwestern peninsula, has an uncontrolled run-off which produces heavy spring freshets, and a consequent low discharge during the late summer and early autumn periods.

The abnormal flow characteristics of the Maitland River to a large extent discount its value as a source of power, the more so by reason of the fact that its watershed is almost entirely lacking in natural storage basins. The country throughout the whole area is cleared and for the most part cultivated, so that the land damages and construction costs in connection with the establishment of remedial works of sufficient magnitude to adequately offset the effects of drainage, cultivation and deforestration would be prohibitive. In view of this fact, the power possibilities of the Maitland River, considered as an independent source of continuous power, can only be discussed on the basis of minimum flow, in conjunction with such advantages as can be derived from local pondage.

The total drop of the Maitland River from headwaters to mouth is approximately 900 feet, but the topography of the watershed is such that no natural heads of any consequence exist, the gradient of the river-bed being fairly uniform and the average velocity high. As a result, power can only be developed by diversion or by the creation of an artificial head, or by a combination of both methods. This condition, in conjunction with the poor run-off regulation, will tend to make power development expensive, and to increase the annual cost of power.

The above general facts and the general conclusions deduced therefrom, comprised practically the sum total of all hydraulic data in connection with the Maitland River which could be safely used when the Huron County scheme first became a definite issue. The proper consideration of the scheme, therefore, necessitated at the outset a systematic investigation of the flow characteristics of the Maitland River. Owing to the desire of the county authorities to have a report at the earliest possible date, it was decided to carry on the hydraulic investigations for one year only, the understanding being that any conclusions arrived at by the end of that period should not be considered as final, but merely as indicating reasonable possibilities. The extent to which this end was attained will now be considered.

Early in May, 1911, a gauging station was established at Ben Millar, and since that date monthly measurements of flow have been made, and in connection with these measurements daily records of level were also obtained.

The records obtained up to the present time are tabulated hereunder:—

Date of measurement.	Discharge. Cu. ft. per sec.	Water level.	Electric h.p. per foot of head. Horse-power.
May 19, 1911	979	14.27	82
June 14, 1911	549	13.80	46
July 20, 1911	305	13.60	25
August 11, 1911	170	13.37	14
September 18, 1911	172	13.39	14
October 16, 1911	257	13.55	21
November 20, 1911	4,068	15.34	340
December 22, 1911	1,280	14.30	107
January 27, 1912	752	Ice	63
February 29, 1912	506	Ice	42
March 28, 1912	2,116	Ice	176
April 6, 1912	41,000	20.26	3,420
April 7, 1912	65,000	21.60	5,420
April 26, 1912	1,437	14.40	120
May 30, 1912	5,815	16.13	485
Estimated extreme minimum on Aug. 30, 1911	120	13.18	10

The last item in the above table is inserted by reason of the fact that there was no actual measurement of flow taken when the water-level reached its lowest stage of 13.18 at Ben Millar, as evidenced by the daily records. The estimated discharge of 120 cubic feet per second is considered to be a generous one and is to be considered the minimum volume of flow so far recorded.

The flow characteristics of the river during the term covered by these records may be summarized as follows:—

(1) The minimum run-off of the watershed was about .125 cubic feet per second per square mile.

(2) The maximum run-off of the watershed was about 68 cubic feet per second per square mile.

(3) The ratio of minimum to maximum flow was at 1 to 543.

(4) The low stages of flow occurred during the months of July, August, September and October.

(5) The intermediate stages of flow occurred during the months of November, December, January, February, March and June.

(6) The high stages of flow occurred during the months of April and May.

These records also indicate:—

(1) That the river is extremely sensitive to the effects of rain-fall.

(2) That the river is seriously deficient in ground storage capacity.

(3) That deforestation, cultivation and drainage have so accelerated the run-off that the ground storage of the watershed can never be filled to its natural capacity. The falling off in discharge from 65,000 sec. ft. on April 7th to 1,437 sec. ft. on April 27th plainly indicated the existence of this condition.

The records so far obtained seem to indicate, therefore, that the discharge of the Maitland is mainly dependent upon surface run-off, and the power capacity of the river from month to month will vary almost in proportion to the monthly precipitation on the tributary watershed. This contention is borne out by the evidence of the May discharge. On May 19, 1911, there was 82 h.p. per foot of head at Ben Millar, with the May precipitation slightly below normal. On May 30, 1912, there was 485 h.p. per foot of head at Ben Millar, with the May precipitation 300 per cent. above normal.

This intimate relation between rain-fall and power capacity indicated the necessity of determining what relation the monthly precipitation during the year covered by the records bore to that of previous years, and precipitation records from all meteorological stations located in or adjacent to the Maitland River watershed were obtained with this object in view. These records proved to be so disconnected and otherwise unsatisfactory that an exhaustive analysis of the same would have been useless. The figures relating to precipitation have, therefore, a low degree of accuracy, and are submitted only because of the impossibility of procuring more reliable data.

The figures in the table below were compiled from precipitation records taken at Goderich for 36 years, at Clinton for 8 years, at Mount Forest for 7 years, at Stratford for 16 years, at Lucknow for 27 years, and at Listowel for 10 years. The first column contains the average of all records of monthly precipitation to date, and the second column contains the precipitation for the corresponding months during which the flow characteristics of the Maitland were being investigated.

General average monthly precipitation for all years.		Monthly precipitation during months of measurement.	Difference Above average.	Difference Below average.
Jan.	3.55 inches	(1912) 4.70 inches	1.15	....
Feb.	2.95 "	(1912) 2.12 "	....	0.83
March	2.62 "	(1912) 1.59 "	....	1.03
April	2.15 "	(1912) 2.10 "	....	0.05
May	2.93 "	(1911) 2.71 "	....	0.22
June	2.91 "	(1911) 2.02 "	....	0.89
July	2.91 "	(1911) 1.90 "	....	1.01
Aug.	2.47 "	(1911) 2.59 "	0.12	....
Sept.	2.86 "	(1911) 3.71 "	.85	....
Oct.	3.39 "	(1911) 4.45 "	1.06	....
Nov.	3.49 "	(1911) 4.33 "	.84	....
Dec.	3.48 "	(1911) 2.13 "	....	1.35

It will seem from the above that the monthly precipitation during the year of investigation fell below the general average during the months of February, March, April, May, June, July and December, and was above the general average during the months of August, September, October, November and January.

While, as previously stated, the reliability of the precipitation data is questionable, several deductions can be drawn from the above figures which have a certain value.

These deductions may be itemized as follows:

1. The average precipitation for the three winter months of December, January and February from the above table is 9.98 inches. The precipitation for this period in 1910-11 was 9.46 inches, or 0.52 inches below the average. The precipitation for the corresponding period in 1911-12 was 8.95 inches or 1.03 inches below the average. It is to be inferred from this that there was a greater volume of spring run-off during the spring of 1911 than there was in the spring of 1912. This condition should reasonably be expected to produce a greater summer flow in 1911 than in 1912, on account of the fuller replenishment of ground storage.

2. The average precipitation for the three months of March, April and May is 7.70 inches. The precipitation for this period during 1911 was 8.21 inches, and for the same period in 1912 was 10.54 inches, being therefore 0.51 inches above the average for 1911, and 2.84 inches above the average for 1912. Under these conditions the tendency would be to produce a spring discharge in the Maitland slightly above

the average in 1911, and considerably above the average in 1912. This should also have a tendency to make the summer flow for 1911 less than the summer flow for 1912, but slightly more than the average.

3. The average precipitation for the three summer months of June, July and August is 8.29 inches. The precipitation for the summer months of 1911 was 6.51 inches, or 1.78 inches below the average. The tendency would, therefore, be for the production of a summer discharge below the average during 1911.

4. The average precipitation for the three autumn months of September, October and November is 9.74 inches. The precipitation during the autumn months of 1911 was 12.49 inches or 2.75 inches above the average. The tendency of this condition would be to produce an autumn discharge greater than the average in 1911, and also to produce a discharge greater than the normal during the winter months of 1911, and 1912.

Applying these deductions to the flow characteristics found by measurement during the years 1911 and 1912, the following conclusions are derived:—

1. The winter precipitation for 1910-11 was slightly less than the average but greater than the winter precipitation for 1912, the tendency being therefore to produce a summer flow in 1911 slightly above the average, and greater than the summer flow for 1912.

2. The spring precipitation for 1911 was slightly greater than the average but much less than the spring precipitation for 1912, the tendency being, therefore, to produce a spring run-off and consequently a summer flow, slightly above the average in 1911, but less than would obtain in 1912.

3. The summer precipitation for 1911 was considerably below the average, the tendency therefore being to produce a summer flow less than the average.

4. The autumn precipitation for 1911 was considerably above the average, the tendency being to produce an autumn and winter flow greater than the average.

As regards summer flow in 1911, we have therefore two factors, the winter and spring precipitation and the spring run-off tending to make it a maximum through the effect of ground storage, and one factor, the summer precipitation, tending to make it a minimum by reason of a summer run-off which was below the average. Inasmuch as surface flow is assumed to be the governing factor as regards the discharge of the Maitland River, it may be reasonably stated that the summer discharge for 1911 was really below the average, and also that the summer discharge for 1912 may be expected to be greater tban that of 1911 and possible above the average.

In the matter of autumn and winter flow, that shown by measurement during 1911 and 1912 is probably much greater than can ordinarily be expected, as the autumn precipitation was so much in excess of the average. Smaller values for discharge are to be anticipated during the coming autumn and winter if, as seems probable, the precipitation more closely approaches the average.

To conclude this portion of the argument it may be said that, as regards the flow characteristics of the Maitland River, the outstanding features are, first, its sensitiveness to the effects of rain-fall, and, secondly, its dependence upon surface run-off as against ground storage. Therefore, while the conclusions above set forth may cover the general behavior of the river over a cycle of years, the occurrence of abnormal or unusual precipitation phenomena during some particular season may give rise to temporary conditions of flow, the nature of which it is not now possible to anticipate.

The initial decision that the Black Hole power-site was the best suited to the requirements of the commission and the county of Huron is amply justified by the results of the subsequent investigation. The minimum capacity of 10 h.p. per foot of head proves the necessity for developing under the highest possible head that topographical conditions will permit and that capital cost will justify, and also for choosing a site providing the best facilities for pondage in order to make peak load and daily storage capacity a maximum. The Black Hole site, with an operating head of 80 feet, and something over 700 acres of pondage obtainable, fulfils the required conditions more satisfactorily than any other possible location on the lower river and has been considered to the exclusion of all others.

Referring back to the table of discharge measurements, the power capacity of the Black Hole site, under an 80-foot head, upon the various dates of flow measurement, would be as follows:

Date of measurement.	Continuous 24-hour power capacity.	Probable combined 10-hour and 24-hour capacity.
May 19, 1911	6,560 E.H.P.	10,000 E.H.P.
June 14, 1911	3,680 "	5,800 "
July 20, 1911	2,000 "	3,200 "
Aug. 11, 1911	1,120 "	1,800 "
Aug. 30, 1911 (min.)..	800 "	1,200 "
Sept. 18, 1911	1,120 "	1,680 "
Oct. 16, 1911	1,680 "	2,400 "
Nov. 20, 1911	27,200 "	38,000 "
Dec. 22, 1911	8,560 "	12,000 "
Jan. 27, 1912	5,040 "	7,100 "
Feb. 29, 1912	3,360 "	4,700 "
Mar. 28, 1912	14,080 "	21,000 "
April 26, 1912	9,600 "	15,400 "
May 30, 1912	38,800 "	62,000 "

Considering the above figures in connection with the conclusions derived from the study of precipitation, the following general statements with regard to power capacity would seem justifiable:

1. The spring flow will, under all circumstances, produce power in excess of economic installed capacity.

2. The summer flow was probably close to the minimum during 1911 and a larger summer power capacity may be anticipated under average conditions.

3. The autumn precipitation and late autumn flow was considerably in excess of the average, so that the power capacities established by measurement during the autumn and winter of 1911-12 cannot be considered normal, and conditions much less favorable should frequently obtain.

Considering the power capacities in connection with the market demand, it is evident that even under average conditions, the summer power capacity of the Black Hole site will not be sufficient to carry the Huron county load, so that some portion of it will always have to be carried by Niagara during the summer season, and probably at times in the early autumn. Also while the autumn and winter capacity may at all times be sufficient to carry the Huron county load, it is by no means certain that sufficient surplus capacity will be available to supply auxiliary power to the Niagara system. As the Maitland River will be obliged to furnish power to the Niagara system during the autumn and winter months to compensate for power obtained from Niagara during the summer, the serious nature of this condition is evident; for unless the Maitland River can furnish auxiliary power during the peak load period when it is required, the summer power supplied by the Niagara system will have to be paid for by the county of Huron.

The projected scheme of development at the Black Hole involves the creation of an artificial head and also a diver-

sion. It is proposed to build a dam of sufficient height to back the water up to Ben Millar bridge and to further increase the head by diverting the flow across the neck of a sharp bend in the river. The additional head obtained by this diversion will be at 5 to 15 feet, depending upon the relative locations of the dam and power-house, and the total average head available would be about 80 feet.

The largest item of capital cost in connection with this development is the dam construction, and before the flow characteristics of the river had been investigated it was thought that earth fill construction could be used for the main dam, but the abnormal flood flow conditions evidenced by this spring's measurements demonstrated the practical impossibility of utilizing this type of construction at the Black Hole. It was therefore necessary to largely increase such preliminary estimates as had been made to provide for a masonry dam, and the hollow reinforced type of construction was adopted as being the cheapest and most economical after giving proper consideration to safe and efficient handling of ice and flood-water.

In a general way it may be said that the conditions relative to development at the Black Hole could not well be more unfavorable, as the low water power conditions are such as to make the revenue-producing power capacities very small, while the flood conditions are such as to call for an abnormally heavy capital expenditure for dam construction and permanent works. The annual cost of generated power is therefore affected by reason of the fact that the revenue from power generated at low stages of flow must be sufficient to cover the heavy capital charges and maintenance costs arising out of the necessity for handling an abnormal flood discharge.

Two estimates of the cost of development at the Black Hole have been made, one for 2,000 h.p., and one for 6,000 h.p. installed capacity. The 2,000 h.p. estimate represents the cost of developing the Black Hole site, as an independent source of power, to the limit of dependable 10-hour capacity. The 6,000 h.p. estimate provides surplus installed capacity for the purpose of using the higher stages of flow to supply auxiliary power to the Niagara system.

The 2,000 h.p. estimate shows a capital cost of $587,000, and a total annual charge of $45,500. The 6,000 h.p. estimate shows a capital cost of $637,000 and a total annual charge of $51,500. Considering these figures in connection with the statements made above as to the effect of a low power capacity, combined with a heavy flood discharge, upon cost, it is interesting to note:—

1. In the 2,000 h.p. estimate, the dam construction amounts to 63 per cent. of the total capital cost, and the annual charges against dam construction alone amount to 51 per cent. of the total annual charges.

2. In the 2,000 h.p. estimate, the interest and sinking fund charges amount to 75 per cent. of the total annual charges.

3. In the 6,000 h.p. estimate, the dam construction amounts to 58 per cent. of the total capital cost, and the annual charges against dam construction alone amount to 45 per cent. of the total annual charges.

4. In the 6,000 h.p. estimate, the interest and sinking fund charges amount to 71 per cent. of the total annual charges.

It is evident from the above figures that the annual cost of generated power at the Black Hole will be high as long as the interest and sink fund continues to be an annual liability, the more so because the revenue from such continuous power as can be generated under conditions of minimum flow will always have to carry the bulk of the annual charge against the development.

FREIGHT RATES BY WATER

The plans of the department of railways and canals for ascertaining the average rate per ton per mile on the inland waters of Canada involved the recording of the freight rates on each ship's report filed at the various canal offices. As an alternative those operators who wished to do so were permitted to send a monthly statement to Ottawa of tonnage, mileage and gross freight earnings. Ship owners were also required to send in at the close of the season a report showing:—Total tons carried, total ton mileage of loaded vessels, gross receipts from freight. On the whole, and having regard to the difficulties which are inseparable from the inauguration of new undertakings of that character, the results obtained during the past year the first of the operations of the plans were satisfactory. For example, out of a net Canadian tonnage of 6,942,278, definite information was received with regard to the mileage and freight earnings on 6,292,661 tons. St. Peters and St. Andrews canals were left out of the scheme for the year 1912, and they accounted for 170,358 tons; so that the actual net Canadian tonnage affected was 6,771,920. Returns were thus received in relation to 93 per cent. of Canadian business. These returns covered all classes of traffic, and it might reasonably be assumed that had every ton been accounted for, the result would not have been altered.

The Canadian returns applied to 6,292,661 tons of freight, to 3,286,187,160 ton miles, and to gross freight earnings amounting to $6,378,893.43.

From United States shipping companies reports were received covering 26,030,661 tons, out of a total net tonnage of 36,840,812. These reports had reference to all classes of commodities, and were thoroughly typical of the whole business on inland waters of Canada. It may be confidently asserted that absolutely complete returns would not have materially affected the final calculation of the average rate per ton per mile. The number of ton miles accounted for amounted to 21,799,392,809, and the gross earnings on United States freight to $14,617,368.60.

Using the factors which have been indicated—the ton mileage and the gross earnings from freight—the results are as follows:—

Canadian traffic:—

Average rate per ton ....91. 04 cents.
" " per mile .... 0.194 "

United States traffic:—

Average rate per ton ....50. 62 cents.
" " per mile .... 0.067 "

Without an explanation, the difference between the Canadian and United States rate per ton per mile will not be understood. Of the 36,840,812 tons of United States traffic through the canals of Canada in 1912, no less than 31,134,251 tons, or nearly 85 per cent., consisted of iron ore. Upbound coal accounted for a further 2,945,441 tons, or 8 per cent. In fact, if iron and coal were eliminated from the total account, the volume of Canadian traffic would exceed that of tne United States.

The transportation of iron ore and coal is a special feature of the trade of the Great Lakes. Most of the ore is carried by the vessels of the Pittsburg Steamship Company, and the rate in 1912 was 55 cents per ton from the head of Lake Superior to ports on Lake Erie. These vessels are owned and operated by the iron interests of Pittsburg, and do not carry other commodities than ore and coal—ore down and coal up. For this upbound coal, without regard to ownership of the vessels, the rate last year was 30 cents per ton. Thus, while wheat was being carried to Buffalo at as high a rate as 2.616 cents per ton per mile, iron ore was passing over the same route at .063. Coal was being moved upward at the still lower rate

of .046 per ton per mile. In a word, any analysis of freight rates on the inland waters of Canada would be misleading which failed to recognize, and to separate for special treatment, this overwhelming movement of ore and coal under the conditions indicated.

Special care was taken during the year to ascertain with accuracy the rates which were charged on waterborne wheat. The facts in that regard were carefully tabulated. They yielded the following results:—

Fort William to Buffalo, per ton per mile, .103 cent; per bushel, 2.863 cent.

Fort William to Georgian Bay, per ton per mile, .163 cent; per bushel, 2.629 cent.

Fort William to other Canadian ports, per ton per mile, .115 cent; per bushel, 2.384 cent.

Fort William to Montreal, per ton mile, .160 cent; per bushel, 5.774 cent.

The lowest rate prevailed in May, and the highest in December.

There was not any wheat actually brought down from Fort William to Montreal in December; and the rates are for November. The largest volume of wheat moved between Fort William and Montreal occurred in October, when the average rates were .184 per ton mile and 6.149 cents per bushel. For the same month the rates from Fort William to Buffalo were .084 per ton per mile, and 2.259 cents per bushel. The maximum rate of the season between Fort William and Montreal was in effect in November, and was 8 cents per bushel.

To measure the conditions which influenced the movement of Canadian wheat to Montreal or Buffalo, it is necessary to know the freight rate on wheat from Buffalo to the Atlantic seaboard during 1912. It was officially ascertained from the Buffalo chamber of commerce, under date of 14th February, 1913, that these rates per bushel were: May to end of September, on lake wheat for export, 4½ cents; in October 5½ cents; after fifteenth November, six cents.

Thus, the all water rate from Fort William to Montreal in May was 5.444 cents per bushel, and the combined water and rail rate from Fort William to the American seaboard (say New York) was 7.219 cents. In November, the water rate from Fort William to Montreal was 7.129 cents per bushel, and the combined water and rail rate from Fort William to the United States seaboard, via Buffalo, was 8.616 cents. The apparent difference in favor of Montreal was 1.765 cents per bushel in May, and 1.487 cents in November, so far as the rates of freight were concerned.

There remains to be presented the facts with respect to traffic by way of Fort William and Georgian Bay ports. The average rate for the season was 2.629 cents per bushel. It was officially ascertained that the rail rates from Georgian Bay to Montreal were as follows:—

	Per Bushel.
Canadian Pacific Railway	6 cents.
Grand Trunk Railway, January 1st to June 30th	5 cents.
Grand Trunk Railway, July 1st to September 30th	4 cents.
Grand Trunk Railway, October 1st to December 31st	5 cents.

Speaking broadly, it might be assumed that the combined water and rail rate is adjusted to practically equal the all-water rate.

Among the causes which operate to divert a large percentage of Canadian wheat from Canadian to United States channels despite the lower transportation cost are:—The availability of ocean tonnage at New York, the consideration of time in making delivery at foreign ports, and the rates of marine insurance. It is obvious that these causes must have continued to operate effectively in 1912.

The question is frequently, and quite naturally, asked: How do freight rates by water compare with freight rates by rail? This question will never be fully and satisfactorily answered until carriers by water are required to report in precisely the way railways are asked to do.

This year, for the first time, accurate information has been obtained with regard to the average rate per ton per mile on the waterborne traffic of the Great Lakes. That rate, so far as Canadian business was concerned, was found to be .194 cent. It is pointed out, however, that this rate does not take cognizance of the special conditions under which traffic on the inland waters of Canada is conducted, and that the contribution of government should be taken into the reckoning. There is pertinency in such a contention. It would seem, at all events, to be proper to include the interest charge on the capital cost of the canals and the annual outlay by government for up-keep. The facts in that regard are definitely known. This plan omits all expenditures for harbors, lighthouses, dredging, buoying, etc., which might be included; but, whether they should be included or not, the matter is ruled out for the time being by reason of the fact that the sum of such expenditures is not definitely known.

HARDENING ARMOR PLATE BY WELDING.

Sheffield steel experts are awaiting with considerable interest further information concerning tests, which, it is stated, have been applied with some success to armor plates manufactured by a new process which, the inventor claims, renders them capable of resisting projectiles of the highest power.

The inventor is William Henry Worrall, of Sheffield. He states that the new armor plate does not at all rely upon any new ingredient for its increased resisting power, but that this is obtained as the result of a different process of hardening, largely secured by the welding or bonding of four or six sheets of metal into one plate, instead of molding the plate as a whole in one ingot. The main object is to effect a thorough homogeneous hardness. This, it is said, will permit of ironclads being as efficiently protected with much thinner and lighter plates than is at present the case.

Several experts express some doubt as to whether the welding of a number of plates contributes to greater homogeneity. They all agree that experiments conducted on somewhat similar lines have not hitherto been attended with success. Dr. J. O. Arnold, F.R.S., professor of metallurgy at Sheffield University, said:

"Practical experience in armor plate manufacture is that you must have the face sufficiently hard and with sufficient depth of hardness to smash up a shell. No reliable estimate can be formed of the value of a plate until it has been drastically tested by the admiralty, under standard conditions. So far as I know there is only one plate of this so-called bonded process of manufacture which has been so tested, and that was a failure. There is a new system of manufacturing armor plates, at present in the experimental stage, which consists of welding a face of high-speed steel on to the relative soft backing of the plate. This has been done with some measure of success, but the ultimate value of the plate can only be determined by an admiralty test. I see it is claimed that Mr. Worrall's plate has withstood a fourteen-inch shell. If that is so, it must have been an admiralty test, because I do not think any private firms are equipped with such a gun.

COAST TO COAST.

Montreal, Que.—The Great North Western Telegraph Company will install in June next between this city and Toronto the Wheatstone high-speed automatic apparatus, which will transmit 400 words a minute, or 24,000 an hour, as compared with 5,000, the record for Morse operators under quadruple operation. The system has been used extensively by the British post-office and the Western Union Telegraph Company, of the United States. Mr L. S. Hume, local manager, recently stated that no reduction of operators would be made on account of the Wheatstone installation. At present, he stated, the growing demands of patrons of the company, both in Montreal and in Canada generally, required increased facilities for handling telegrams. The new arrangement will enable the Great North Western to better cope with their largely increased business. It is learned that one circuit of the new installation will require a staff of twenty-six persons to properly operate one wire only. Three operators will look after a perforating electrical machine run from a typewriter keyboard. A punched tape, which is fed by a "transmitter" working at high speed, where the signals are transferred to a tape by a "receiver." The tape is then handed to typewriter operators, who copy them.

Ottawa, Ont.—Mr. W. A. Legge, the British engineer sent here by Sir Alexander Binnie, has started work in connection with the proposed water supply from the Gatineau lakes. He is first getting the information which may be gleaned from plans and reports in the city engineer's office and from information given Dr. King by the Government parties of surveyors. About the end of this week he will go to the lake district and take charge. There are two Government parties out. One is working around Little Whitefish, Thirty One Mile and Pemichangaw Lakes, and the other is taking levels between Gracefield and Ottawa. After looking over the ground, Mr. Legge will direct what particular work he wants done first and the areas covered. He is not a member of Sir Alexander Binnie's firm, though sent here by him. He is prepared to stay all summer, if necessary, but says no time will be lost. He hopes to get the required information so that Sir Alexander Binnie may make his final report before the winter.

Selkirk, Man.—George H. Bradbury, member for Selkirk, introduced for a second reading to the Dominion Government his bill to prevent the pollution of navigable streams Mr. Bradbury, in opening, pointed out that Canada had spent millions in the material development of the country, in building railways, canals and public works, while little had been done for the health of the people of the Dominion. Providence had been lavish in providing waterways for Canada, but we had neglected to protect these waterways, and they were now proving a menace. Twenty-five years ago the Ottawa River was pure, and to-day one glass of its water contained misery and death to those who had the temerity to drink it. The records of death from typhoid was an awful record for a city like Ottawa. Mr. Bradbury quoted figures prepared by Dr. Charles Hodgetts, of the Conservation Commission, to show the toll of death from typhoid in Ottawa, Winnipeg and other Canadian cities. In Canada the death rate from typhoid was 35.5 per hundred thousand of the population. In Germany it was only 7.6; England, 11.2; Belgium, 16.8; Austria, 19.9; Hungary, 28.3, and Italy, 35.2. In the face of these figures surely it was time that Canada did something, and put an end to the abominable practice of dumping sewage and offal into streams. Typhoid, Mr. Bradbury said, was a preventive disease, and he quoted several sanitary experts on the subject. It was time, in view of the epidemics which had taken place in Ottawa and other Canadian points, for drastic action. During the past ten years there had been no less than 5,796 deaths from typhoid in Ontario alone. He did not believe loss of life could be estimated by money. But, placing each life at $3,000, this meant a total of over $17,000,000. There had been in that time 50,000 cases in Ontario. Each patient lost on an average ninety days, which, at $1.50 a day, meant $6,500,000 in wages. Nursing is placed at five million more, making a total loss in Ontario of $28,000,000. This amount would have been sufficient to give a proper system of sewerage to all the important cities of Canada. On this basis of reckoning the city of Winnipeg had lost five million dollars. Mr. Bradbury explained the situation at Winnipeg. There were two rivers which united at Winnipeg. The Assiniboine flowing from the west carried down the sewage of Brandon and Portage la Prairie. It emptied into the Red River in the heart of the city, and the Red River flowed north with the sewage of Winnipeg, with all its manufacturing plants, and the sewage of Brandon and Portage. Four or five years ago the Government built a dam at St. Andrew's Rapids. Previously the current of the Red was fairly swift, and, while the river was contaminated, it carried the nuisance away. Now the Red consisted of a large basin twelve miles long and one hundred yards wide. The Red, with all this sewage, flowed through Selkirk, and at that point the water was unfit even for cattle to drink. Men could not water their horses in it. Lake Winnipeg had been contaminated for eight or nine miles, and nearly every year there was an outbreak of typhoid among the men who work on the dredges.

Sydney, N.S.—One million four hundred thousand gallons of creosote could have been produced in Western Canada in 1910 if the coal that was converted into coke had been coked in by-product ovens. This is the somewhat startling statement made by the Dominion Commission of Conservation. With the exception of the creosote produced from the by-product ovens at Sydney, N.S., and at Sault Ste. Marie, Ont., no creosote is produced in Canada. This valuable wood preservative is imported from Britain and the United States, but the high cost of the imported article has restricted its use very materially. In view of the steady and even rapid rise in the price of almost all classes of wood products, the importance of creosote is readily seen. For example, there is the problem confronting Canadian railways in obtaining timber from cross-ties. There were 13,683,770 ties purchased in Canada in 1911, an increase of 48.5 per cent. over the figure for 1910. When it is considered that the annual replacement of ties on existing lines amounted to about 10,000,000, it is evident what enormous quantities of tie material are required in order to supply the demand. This demand will not remain stationary, but, on account of the increased mileage of railways being constructed in Canada, will increase each year. Owing to the other demands for lumber and wood products, the price of cross-ties has been steadily increasing. The cost of tie maintenance is now a large item of expense, and the higher prices of the better grades of wood have forced the railway companies to use inferior woods. In 1908 cedar ties constituted 40 per cent. and jack pine (an inferior wood) 10 per cent. of the total used on Canadian railways. In 1911, the proportions were, cedar, 5.3 per cent. and jack pine, 39.9 per cent. In order that the lower grades of wood may be economically used for ties it will be necessary to creosote those species that fail through decay. In order, also, to utilize ties of the softer woods, it is necessary to use tie-plates. When it is remembered that the average life of an untreated tie is seven years, while the life of a treated tie is seventeen years, the importance and value of creosote is readily seen.

Montreal, Que.—Should the plans for the enlarged Montreal waterworks have been submitted to the International Waterways Commission? That is a question which several eminent engineers are asking, and which has resulted in an enquiry into the matter. When the enlarged aqueduct is completed there will be a flow of 6,500 cubic feet per second from the St. Lawrence above the rapids into the waterworks canal, or about one-eighteenth of all the water of the St. Lawrence. This, it is claimed, will have a direct effect in lowering the level of the water above and along the rapids. Therefore, the plans should have been, or should now be, submitted to the Waterways Commission. It has been decided that plans for power plants in the Cedar Rapids and other points must be submitted to the Waterways Commission, and that the enlarged Montreal Waterworks, drawing such a supply of water from above the rapids, should necessarily fall under the same category. In discussing the matter, Mr. T. W. Lesage, superintendent of the Waterworks, stated that: "The plans were never submitted to the Waterways Commission, and there was no reason why they should be. We are drawing the water out of the river near the rapids, and it is going back into the river near Victoria Bridge. I cannot see that the enlarged works will have any effect upon navigation." "Our enlarged waterworks," says Controller Godfrey, who has special charge over the waterworks, "cannot have any effect upon navigation, except as regards the small river steamers. It will not affect the water in the canal. The water flows into our canal above the rapids, and flows right out again lower down, so that it will not affect the level of the river in the harbor. In any event, the plans for the enlarged plant were completed before the present Waterworks Commission was in existence." Against all this, it is claimed that the plans should be submitted to the Commission, even if it were only as a matter for formality, just the same as power projects in relation to the St. Lawrence are submitted as having international importance. City hall officials assert that when the plans for the waterworks were passed some years ago, they were recommended by three expert engineers, who pronounced that they would not interfere with navigation.

PERSONAL.

MR. GEO. B. WILSON, secretary to the mayor of Toronto, has been appointed the head of the street cleaning department, which is to be reorganized.

MR. W. R. SWEANEY, recently acting general manager of the Toronto Hydro-Electric system, has been appointed sales manager of the Toronto Electric Light Company, taking the place of Mr. Parker Kimble, who received an important appointment at Cincinnati.

E. BRYDONE-JACK, Professor of Civil Engineering, University of Manitoba, has opened an office as consulting engineer at 305 Boyd Building, Winnipeg. He will conduct a general consulting practice covering the fields of bridge, structural and concrete work, power development, tests and inspection, etc.

CUMMINS & AGNEW, consulting engineers, Vernon, B.C., have been appointed as city engineers of Vernon, B.C. This consulting firm was recently organized, and consists of a partnership of several established practising engineers. They have several irrigation projects on hand, and are engineers to several towns in the Okanagan Valley. They are undertaking all classes of civil engineering work, both consulting and constructing. Associated in the firm are A. P. Cummins, C.E., B.C.L.S., J. C. Agnew, B.C.L.S., F.R.G.S., D. M. Mathieson, B.Sc., C.E., and J. C. [illegible], M. C. Soc. C.E.

PROF. VAN, graduate of McGill University, Montreal, at present head of the College of Mines of the University of Minnesota, of which university he has been associated with for the last fourteen years, has been appointed director of the department of mines and metallurgy of the Panama-Pacific Exposition, to be held in San Francisco in 1915. He is a native of Holland, and he has had an extensive experience in practical mining work in the United States, Mexico and Canada.

Plans for the Palace of Mines and Metallurgy show that it will be one of the handsomest of the fourteen exhibit palaces now being erected at Harbor View, the exposition site. The extent to which the subject is to be featured at the Panama-Pacific international exposition is indicated by the classification of exhibits in this department, just announced by Capt. Asher Carter Baker, director of exhibits. There will be five groups, subdivided into fifty-eight classes, which will include displays relative to equipment and methods of geological surveys, mining bureaux and other societies for the promotion of mining.

Prof. Van, Graduate of McGill and Director of the Panama-Pacific Mines Metallurgy Exhibit.

The exhibit in its entirety will not only afford exceptional educational opportunities to the public in general, but will be of particular value to mining men in the special fields of their activity.

H. B. PULLAR, Assoc. Am. Soc. C.E., and C. H. ENZENROTH, B.S., announce the opening of their consulting laboratory at 378 Woodward Avenue, Detroit, Mich. Mr. Pullar was formerly assistant manager and chief chemist of the American Asphaltum and Rubber Company, Chicago, and has had long experience in the testing of asphalts and bitumens, and the practical handling of these materials in the construction of roads and pavements, having made and supervised the mixes on approximately 10,000,000 square yards of bituminous roads and pavements of various types.

Mr. Enzenroth is a graduate chemical engineer of the University of Michigan, and has for the past few years been associated with Mr. Pullar. The firm will make a specialty of road and pavement inspection and the testing of bituminous materials. They have a plan for the inspection of pavements which they claim is new, practical and thorough. They intend to give special attention to municipal plant work.

In our issue of April 24th, under the heading of "Personals," a slight inaccuracy occurred when reference was made to the organization of the firm of McPhie, Kelly & Darling, of Hamilton. We find that Mr. McPhie has had an established architectural business there for eighteen years, and Mr. B. F. Kelly, O.A.A., has been associated with him for five years. It was Mr. Darling, not Mr. McPhie, who was connected with the Hamilton Bridge Works Company for fourteen years. We are glad to place this matter correctly before our readers and regret the mistake made. It is the firm's intention to conduct a combined architectural and engineering practice.

COMING MEETINGS.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, T. S. Young, 220 King Street W., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Mucklestone; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson. Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290. Meets 2nd Thursday in each month at Club Rooms, 584 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson. Sask.

THE ALBERTA L. I. D. ASSIOCATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, The Thor Iron Works, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O. Box 7, St Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

An Engineering Weekly

FREIGHT TERMINALS AND FREIGHT HANDLING AT TERMINALS.

By J. S. BUSFIELD, B.Sc., A.C.G.I.*

(Continued from last issue, page 680.)

There are a number of different systems of telpher carriers in use to-day which are giving satisfaction, and this seems to be a method capable of development to give very efficient service. It has been proved that distance of travel is a comparatively small factor in the cost of handling by telpher carriers, this fact enables a plant to be installed and operated at comparatively low cost, even where there is quite a long haul.

In a freight terminal it is always desirable that every square foot of space should be covered by the carrier and this is very hard to accomplish with an ordinary telpher, except by a method of "transferage" designed by Mr. W. McL. Harding, of New York, which will be described later.

Telpher carriers are now becoming such a regular feature in connection with freight handling that quite a number of manufacturing concerns are prepared to install them in large houses guaranteeing a saving in the cost of handling that will pay the expense of the installation in from one to two years, depending on the amount and kind of freight handled. It has been asserted that certain manufacturers will agree to install overhead electrical appliances which would transfer freight 1,500 feet at a cost of 5 cents per ton

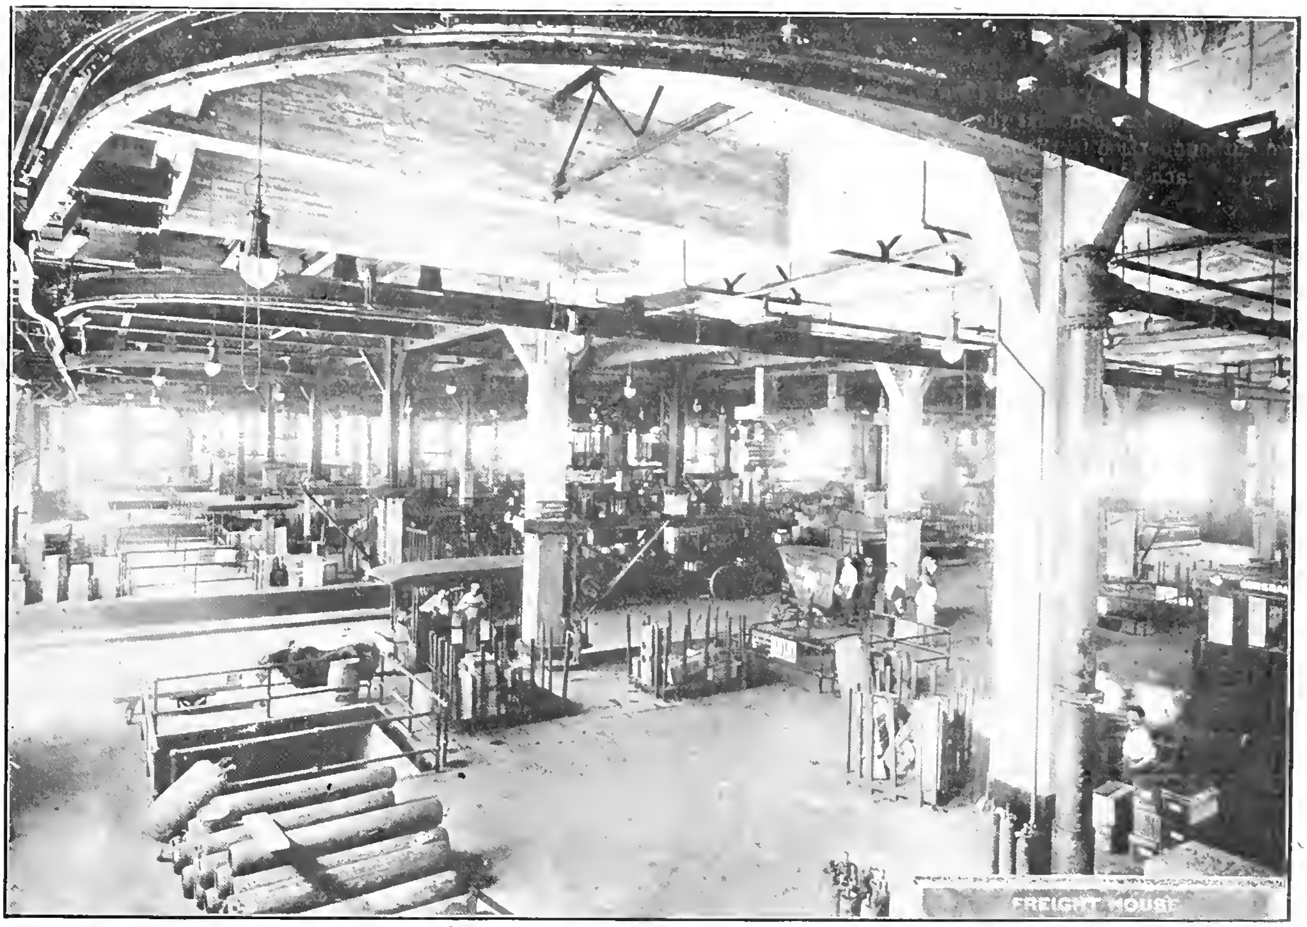

Fig. 11.—General View of M., K. & T. Terminal at St. Louis, Showing Telpher Tracks and Switches; also Tramways Platforms and Hatchways.

* With the Montreal Tunnel and Terminal Company.

for that portion of the work which is now costing more than 25 cents per ton.

A typical arrangement of an overhead telpher carrier system is that in operation at the Bergen, N.J., freight house of the Erie Railroad. A general plan of the houses is given in Fig. 8. It will be seen that there is one inbound platform and two outbound 1,400 feet long with a carrier running down the centre of each platform and connected with cross tracks and switches at each end. A detail view of the carrier truck and running track is shown in Fig. 9. This type is illustrated as being a general sample of a great number of telphers in use. Ten machines operating at one time on the three tracks keeping to the regular routes indicated by the arrows in Fig. 7, would be able to handle 1,000 tons of freight in a day of 20 hours, allowing each machine 6 minutes to make the round trip of 3,000 feet. The average speed of each telpher would be 500 feet per minute, including all stops for picking up and setting down the loads and the maximum travelling speed 1,500 feet per minute.

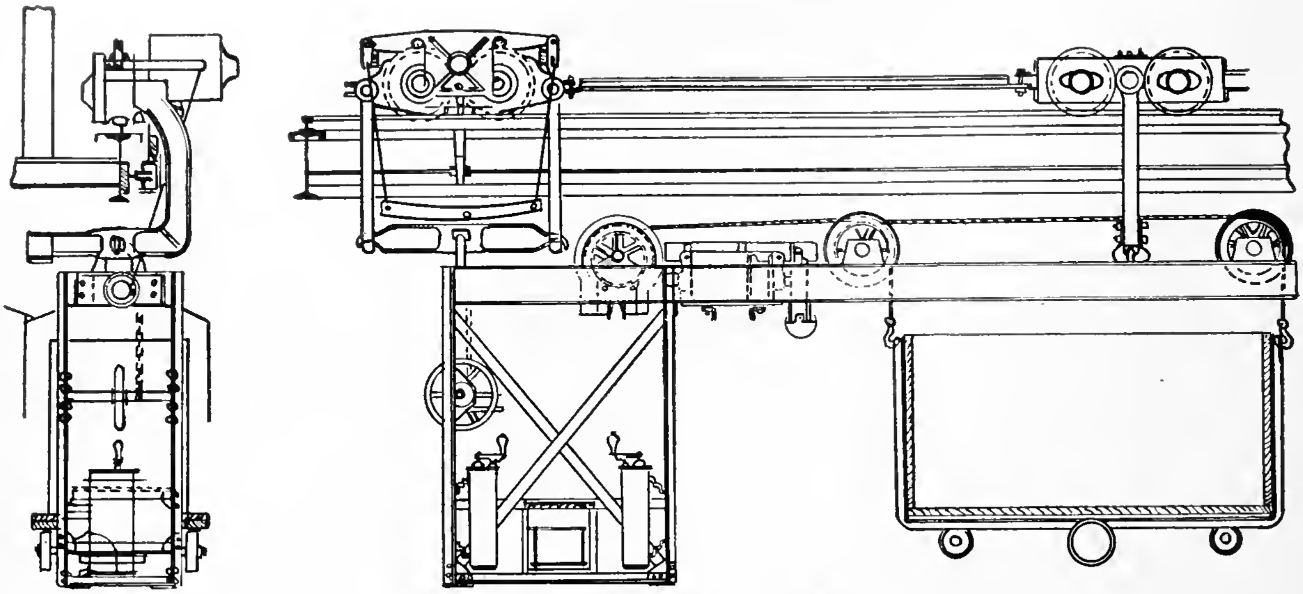

Fig. 9.—Details of Telpher Carrier and Truck.

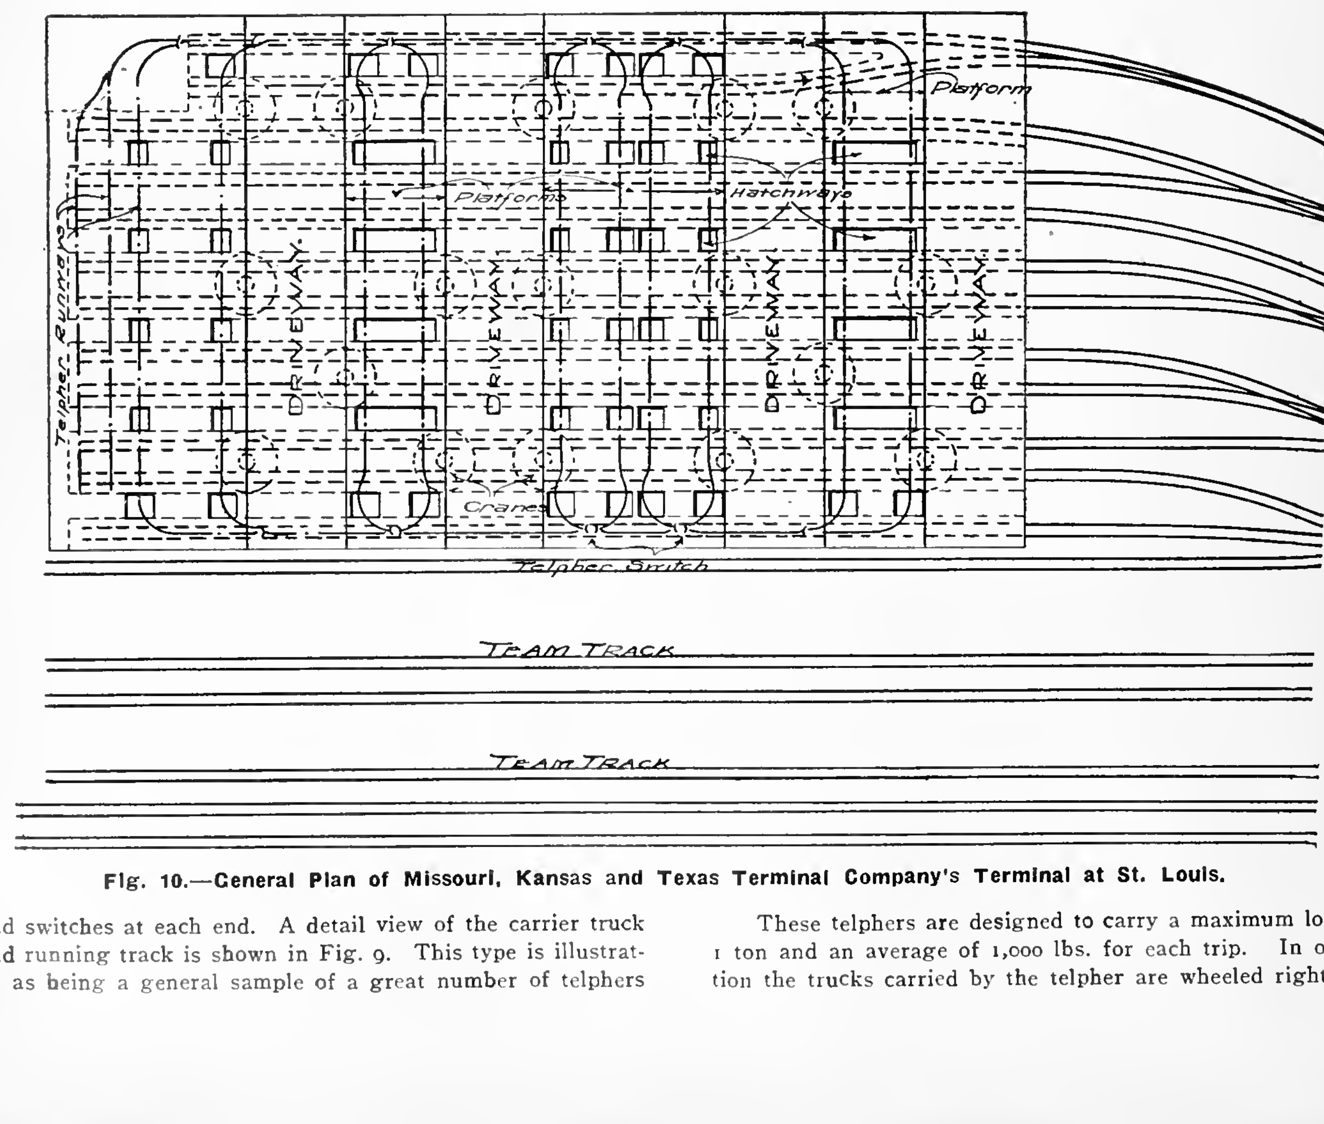

Fig. 10.—General Plan of Missouri, Kansas and Texas Terminal Company's Terminal at St. Louis.

These telphers are designed to carry a maximum load of 1 ton and an average of 1,000 lbs. for each trip. In operation the trucks carried by the telpher are wheeled right into

the freight cars, where they are loaded up with merchandise and then wheeled out to the centre of the platform. The telpher carrier comes along overhead, picks up the load and carries it to the outbound cars, where it is lowered down opposite to the car into which the load is to be deposited. It is then wheeled into the car and unloaded from the truck.

The cost of handling in this manner had been figured at 5 cents per ton, exclusive of the labor cost of trucking the load from the car to its position below the telpher.

The Missouri, Kansas and Texas Terminal Company has erected at St. Louis a double deck freight terminal with the object of reducing the terminal costs, congestion and loss of time in handling L.C.L. freight.

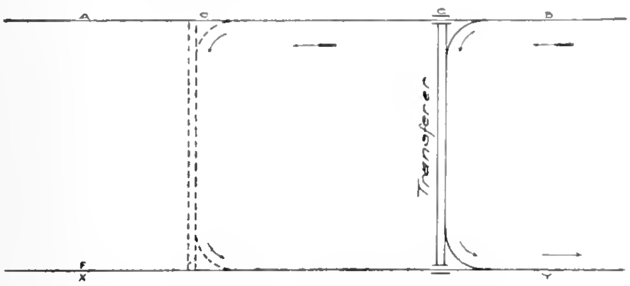

Fig. 12.—Transfer System.

The ground floor of this terminal is occupied by the tracks and cars, and the upper floor is kept entirely for the receipt, delivery and storage of freight. The freight is all transferred from the cars to the upper floor and vice versa by means of an overhead telpherage system, the runways of which are located over the second story. These runways run across the house at right angles to the tracks and in the same direction as the teamways and platforms. At each side of the house is a track connecting all the cross tracks so as to make complete circuits for the telphers. The switches at these end tracks are automatically operated by electricity. A general plan of the building arrangement is shown in Fig. 10, and a view of the team floor, telpher tracks and hatchways in Fig. 11.

The building itself is a structural steel building with brick walls and reinforced concrete floors. In plan its dimensions are 403 ft. by 232½ ft., and accompanying the freight house proper are team, switching and storage tracks and an automobile shed, the whole occupying two and a half city blocks. The shed and mechanical handling plant is designed to handle 100 tons per hour and 75 per cent. of the freight handled is outbound; the capacity of the shed is at present 77 cars, but provision has been made for future expansion. On the ground floor of the building twelve tracks enter from the open north end by ladder tracks with four branches. Each track has a maximum capacity of nine cars. The tracks are spaced in pairs opposite island platforms between the columns supporting the building. With this arrangement trucking through the cars is eliminated and a fixed uniform column spacing is obtained. The platforms are made wide enough to allow two trucks to pass each other.

Immediately east of the building are four team tracks with a capacity of 60 cars, 20 of which are served by a 12-ton gantry crane.

In the upper floor of the building there are four driveways 38 feet wide extending across the width of the building. Alongside the driveways are four platforms, two 82 feet wide and 230 feet long which provide storage space for inbound freight and two narrow platforms 42 feet wide and 217 feet long for receiving outbound freight. All the package freight is loaded up into small platforms or trucks on wheels, which in turn are picked up bodily by the telpher.

The telpher runways are located longitudinally above the wagon platforms, i.e., in a direction at right angles to the tracks on the lower floor. Two runways are provided for each of the 42-foot platforms and for one of the 82-foot platforms, the other 82-foot platform is supplied with four runways. The wheeled platforms and all the loads are transferred from the cars to the teams and vice versa, through a number of hatchways in the floor to the upper level. These hatchways are placed over the low level platforms and below the telpher runways, and so spaced that there is one hatchway for every two cars. Practically no trucking is done on the lower level because all the transferring of freight is handled by the telphers which pick up the load at one hatchway and take it to any other hatchway over the car to which the load is to be taken, here the load is lowered to the cars. At present there are 18 telphers, 16 of which are of 2-ton capacity and the remaining 2 are of 6 tons capacity.

There are 100 wheeled platforms or trucks each 4 feet wide and 6½ feet long, supported on two 10-inch side wheels. Small castor wheels at each end. An arrangement of ratchet lever is fitted to enable one man to move a full loaded truck even up an incline. The telpher machine can hoist these trucks at a speed of 60 feet per minute and travel with them at 500 feet per minute.

In addition to the telpher system there are 17 jib cranes attached to the building columns for loading and unloading the freight from and to the wagons. Fourteen of these are of 1 ton and three of 5 tons capacity.

Transferage.—These two systems of telpherage described have the disadvantage that the carriers must travel over fixed routes and therefore cannot cover areas. A system has been devised by Mr. McL. Harding which will overcome this difficulty by enabling the telphers to cover areas instead of lines. He gives this system the name of "Transferage System."

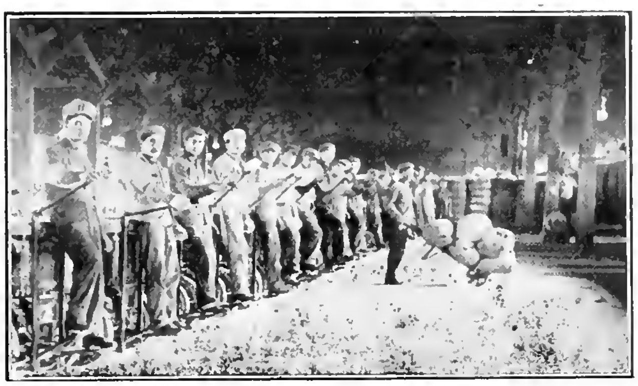

Fig. 13.—Electric Trucks Ready for Use in Freight Sheds.

A diagrammatic sketch illustrating this system is shown in Fig. 12. It is in effect a combination of overhead travelling cranes and travelling trolley or telpher hoists. The following paragraph is taken from Mr. Harding's brief description:

In Fig. 12 let the line A B correspond to the telpher track. A transfer or electric carrier can run in either direction. The transfer travelling in the direction of the arrow at the points C can pass upon the moving switch S and then upon the transferer, which is movable similar to a travelling crane. The transferer is not supposed to move with the telpher and load but can do so if necessary. The load can, therefore, be deposited anywhere in the space between the two lines A B and X Y. The dotted cross lines show the transferer after it has been moved to the left. There may be

two transferers mutually connected upon the same tracks and sets of switches upon each side thus working from cross-overs.

This system seems to be capable of being adapted to suit the varying requirements of a freight terminal. The telphers can be driven at a speed of 500 to 1,000 feet per minute and the transferers, only having short distances to travel, could move at about 100 feet per minute. Trailers might also be used with the telphers and with this system the cost of hoisting, travelling and lowering should not be very high, even for long travel distances.

Motor Trucks.—In the last few years a number of electric storage battery trucks have been put on the market by different concerns and are being quite largely installed in freight terminals. Among the first trucks of this type to be put into use were those of the New York Central at the Grand Central station and the Pennsylvania New York terminal, which were used solely for the handling of baggage. Since then, however, they have been modified and varied into different forms suitable for handling package freight. This type of truck is illustrated in Figs. 13 and 14. Fig. 13 shows trucks ready for use in a freight station, and Fig. 14 shows one loaded.

These trucks have the great advantage of their flexibility, hence their ability to pick up a load at any point in the freight shed and then take it right into the car where the load is to be stowed. This feature, together with their carrying capacity, has in many terminals where they have been installed, enabled the freight handling force to be reduced as much as 50 per cent., with consequent reductions in the terminal costs of handling the freight. The Erie Railroad has at its Jersey City transfer some 20 trucks handling 45 cars of transfer freight and 75 to 85 cars of outbound freight daily, and after an exhaustive test covering the greater part of a year it was found that they were able to reduce the cost per ton from 39 cents to 29 cents, including the cost of running repairs to the trucks.

The following table gives details of the daily average service of motor trucks on a large New York pier:—

Mileage	13.6
Tons handled	225.0
Tons per hour	20.3
Loads handled	230.0
Length of haul	1,585 ft.
Pieces per load	29.8
Weight per piece	88.5 lb.
Time per round trip	2.89 min.
Time to load	58.00 sec.
Time to unload	60.3 sec.
Men in gang	8

A very complete series of tests were made at Providence, R.I., in connection with the performance of these motor trucks, and the accompanying table gives the figures obtained. In the first row the figures refer to the results obtained at the Providence transfer platform, the second is the outbound freight house, third is the inbound freight house, and the fourth is the Providence line pier, Fox Point.

A few general dimensions of the trucks generally in use will not be out of place. Their over-all lengths are usually between 9½ and 10½ feet, with a corresponding length of platform of 6½ to 8 feet. The widths of standard trucks

Fig. 14.—Electric Truck Hauling a Heavy Load of Freight.

varies from 3 to 3½ feet, while the height of the platform above the ground is about 20 inches. The wheel base is made 52 inches and the gauge varies around 3 feet as an average. They are made with varying capacities but the standard trucks as manufactured now do not exceed 3 tons in capacity with the weight of the truck about 1 ton. They are usually designed to give a maximum speed of 10 m. per hour, with a range of intermediate speeds.

The use of these trucks is naturally only in its infancy, but where they have been installed they certainly have shown marked decreases in the cost of handling freight.

Conclusions.—In summing up and studying the relative merits of the different systems of handling freight by mechanical means, each system will be found to have its disadvantages; for instance, in the case of an overhead telpherage system, the telphers are practically confined to fixed lines of travel, and the loads which they have to handle have to be

" " 12 " " *2 & *3.

transferred into the cars by hand. This disadvantage can be reduced though by the use of a number of wheeled platforms such as are in use at the St. Louis terminal previously described.

Again, taking the use of electric storage battery trucks, they are able to overcome this difficulty of the telphers, but on the other hand, they have the disadvantage of requiring a great deal of platform space on which to make their necessary movements, which space might be advantageously used for storage purposes in the case of a telpher system. Another disadvantage of motor trucks is that in order to handle a large business it would require more motor trucks than telphers on account of the fact that the truck has to wait for the unloading and loading up, whereas the telpher carrier picks up or deposits its load and continues its journey to take another load, and it is continually doing efficient work. For this reason it does not seem as though the motor truck could be so efficient as a telpher system, as it can hardly be conducive to economy to have an expensive piece of machinery lying idle for some length of time. Possibly this difficulty can be overcome by the use of trailers, or with small platforms or removable bodies to the trucks. This is a development which no doubt will soon be put into practice.

In designing a freight terminal engineers should take great care to consider the question of mechanical handling of freight. Even if there is no intention of making such an installation immediately, provision should be made for the future handling of a growing business by mechanical means, by looking into the subject and ascertaining what method is most suitable to the particular conditions and requirements of the terminal in question and, if necessary, making such alterations to their design that will enable the necessary machinery to be installed when the business at the terminal warrants the additional expense.

The following table gives a few figures which have been gathered from various sources and which are of use in figuring on the design of a freight terminal:—

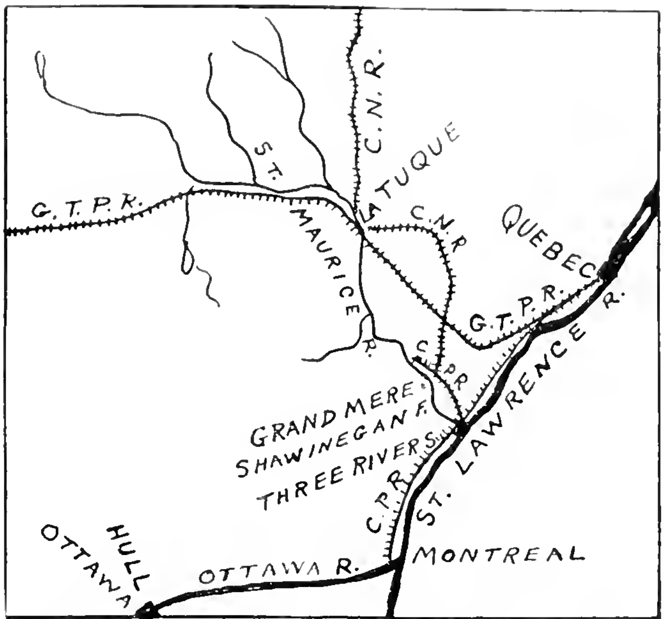
Average load on hand truck	225 lbs.
Average trucker's speed (per minute)	125 ft.
Average tonnage in a car (varying in different localities)	10 to 20
Average cubic feet in a car	1,200
Average width of drays	6 ft. 3 in.
Maximum width of drays	8 ft. 6 in.
Minimum width of drays	5 ft. 0 in.
Average length of drays and teams	20 ft. 0 in.
Maximum length of drays and teams	34 ft. 0 in.
Minimum length of drays and teams	13 ft. 0 in.
Average speed of telphers (per minute)	600 ft.
Maximum speed of telphers (per minute)	1,500 ft.
Average speed of motor trucks (per hour)	6 miles
Maximum speed of motor trucks (per hour)	10 miles

In conclusion the writer wishes to express his indebtedness to Mr. John A. Droege, superintendent of the New York, New Haven and Hartford Railroad for his kind permission to use his book "Freight Terminals and Trains" from which many of the diagrams and data contained in this article were obtained, and to the Sprague Electric Company, of New York, for the illustration of the St. Louis terminal of the Missouri, Kansas and Texas Company.

A concrete bowstring roof truss is a feature of the recently constructed Belleville Theatre in Paris, France. The truss has a clear span of 69 ft. and an overall height of about 15 ft. The top chord approximates a parabola and is connected with the bottom member by six vertical suspenders, spaced about 10 in. on centres.

ST. MAURICE VALLEY FOREST PROTECTIVE ASSOCIATION.

One of the most significant gatherings held in Montreal was the annual meeting of the St. Maurice Forest Protective Association held recently at the Place Viger Hotel. This organization, which is just one year old, marks the beginning of a new era in forest protection. Hitherto the matter of protecting the forests has been one between the individual limit holder and the government. In this field the advantages of co-operation are very great, but until the formation of the St. Maurice Association every lumberman battled with the fires on his own limits as best he could. A year ago the limit holders in this valley, seeing the waste and inefficiency of individual effort, got together and formed an association. They appointed a general manager who took charge of all the fire rangers and directed them as one army, posting every man where he could be of the greatest advantage. The association, which controls an area one hundred and sixty miles



Map Showing Location of St. Maurice Valley, Quebec.

long with an average width of one hundred miles, embracing in all seven million acres, taxed itself one-quarter of a cent per acre, and to the $17,500 thus raised the government of Quebec added $3,000. With this money there were opened or re-opened 525 miles of pack trails, there were purchased canoes, axes, shovels, tents, and gasoline motors for railway patrol, and a beginning made in erecting telephone lines and in connecting these with existing telephone systems. The result was that 97 incipient fires were promptly extinguished and the association came through the year with practically no loss. This year it is proposed to extend the trails, to connect up the telephone lines and to erect lookout stations from which watchmen may send out warnings to headquarters so that a sufficient force of men may be sent promptly to put out the fire. The officers for the first year were: President, Mr. Alexander MacLaurin, of Montreal; vice-president, Mr. W. R. Brown, of Berlin, N.H., and La Tuque, Que.; manager, Mr. H. Sorgius, of Three Rivers. Owing to the illness of Mr. MacLaurin which has necessitated a trip to the south, and the occupation of Mr. Brown with other features, these gentlemen (though both are enthusiastic over the work) retired and the new officers elected were: President, Joseph Dalton, Three Rivers; vice-president, S. L. de

Carteret, La Tuque; manager and secretary, H. Sorgius, Three Rivers.

One of the successful features of the gathering was the banquet at the Place Viger Hotel when about twenty-five gentlemen, members of the association or interested in the work, discussed an excellent menu and afterwards listened to a few pithy speeches.

UTILIZING SAWDUST.

By C. W. R. Eichoff, M.E.

The inconvenient process of burning this valuable waste, taking into consideration the fact that this sawdust, when moderately dry, has the same heat value as the wood from which it originates, has led to the design and construction of many different styles of furnace, which in some cases have brought a betterment and in others failure. Furnaces of the "Dutch oven" style are mostly used in this connection, and especially with boilers. But there are other convenient constructions now in existence. In all these furnaces the main effort was directed to a better distribution of the air necessary for a successful combustion of the material.

Abroad, where conservation of the natural resources has been practised to a greater extent than on this continent, experiments have been made to form this dust into briquettes. At present a number of briquetting plants are in successful operation across the Atlantic, and of later years lumbermen and other mill-owners on this side of the Atlantic have become interested in the briquetting of such sawdust. But the American has not looked favorably on this utilization. The large lumber concerns considered it more profitable not to bother with such a process, claiming that these briquettes can be used only to a small extent and could not compete with other fuels in which this continent is so rich. More interest in the matter was shown by the smaller concerns, where the loss of such valuable wood wastes demands serious consideration. Many owners took up the proposal, but dropped it when they learned the cost of such sawdust briquetting plants. Considering that a product has to be manufactured which requires for its fabrication either a suitable binder or great pressure not using a binder, it is essential that every part of such a plant be designed and constructed with the utmost care and skill in all its details.

Suitable binders are water-gas, pitch, tar, rosin, flour, water-glass and others of the same nature as used in the briquetting of coal. As these binders materially increase the cost of manufacture, their use was found prohibitive, and machines are now used that deliver the goods without the application of a binding material.

The sawdust in this process has to be perfectly dry before being put into the press. From the press the briquettes are transported automatically into a cooling room, and when cool they are hard and ready for transportation. Such briquettes are an excellent fuel for residence use in fireplaces and stoves, do not corrode, and leave very little ashes and soot. The cleanliness, rapid ignition, intense heat and odorless combustion make them a fuel preferable to the best wood. They are also the most convenient fuel for power house use in saw-mills and in logging locomotives, replacing coal or sawdust, which latter would take considerable space. They are also very convenient as a kindling material. The briquettes are of oval form, to facilitate ventilation when piled up.

Presses are built with a capacity of 24 briquettes a minute, giving 14,400 briquettes in ten hours, each briquette weighing about half a pound, which would be equivalent to a daily output of 3.6 tons. The power required for the driers and this press amounts to about sixteen horse-power. Another press has a capacity of nine tons a day, requiring 45 horse-power for the machine.

Use for Dry Distillation.—A very attractive process is the charring of sawdust and subjecting it to a process of dry distillation. The remaining charred material (charcoal) is then briquetted and yields a briquette of very high heat value, equivalent to the best anthracite coal. The process is practically the same as that used in the distillation of wood. The resulting by-products are an illuminating gas, which can be used to light up the mill, wood vinegar or pyroligneous acid, wood spirits or methyl alcohol and wood tar. The wood tar can be subjected to further treatment and yields creosote, benzol, naphthalin, paraffin, etc.

Sawdust has been used for the operation of gas producers for power purposes, in which cases it can be handled either in the loose form or in the form of briquettes.

Related to the briquetting of sawdust is the manufacture of artificial wood. This material is of great tenacity and strength, does not decay and is less susceptible to the action of the atmosphere than is natural wood. All this artificial wood can be sawed, planed and cut, but not split. The manufacture of it has become quite an industry abroad. Decorations for walls, ceilings and furniture are manufactured from mixtures the essential part of which is sawdust. These ornaments rival carved work and are a great deal cheaper, replacing those made of zinc, papiermache and artificial stone or cement.

Sawdust is the essential part of a stone-like material used for building purposes and also for paving blocks. These paving blocks are said to outlast the regular creosoted wood blocks.

Sawdust is pulverized and used instead of sand. In this state it can be colored, perfumed and used for many purposes, such as for sachet bags and the like.

Miscellaneous Uses.—The writer remembers the time when this fine sawdust was used in offices instead of sand and blotters. Its polishing qualities in the pulverized state for gold and silverware are well known. Further, from fine dust of colored wood, such as mahogany, etc., stains can be made to be used in imitating other woods. With linseed oils one can make a filler. The material for this filler is best obtained from the kind of wood on which it is to be used.

Sawdust and shavings are used for packing glassware, porcelain and other ceramic articles. In this state it must be dry, so as not to have a detrimental effect, especially on ceramic goods.

The use of sawdust for cleaning floors is too well known to need mention; not so generally known is its property of preserving eggs.

Any person handling oily and painty tinware should know that it is an excellent means for cleaning fresh paint from such tinware, rendering the vessels perfectly dry and clean.

Sawdust is used in the manufacture of insulating material for steam boilers and steam piping, and as insulating filler in fireless cookers, ice boxes, walls, etc.

It can be laid in cement floors instead of sand, rendering these floors warmer and more porous. It is used for roofing material instead of sand, making roofing paper lighter for transportation and so reducing cost.

Charred sawdust is an excellent means for filtration of liquids and has disinfecting qualities, making it more suitable for this purpose than ordinary charcoal. Added to brick it makes a more porous brick. Mixed with clay it can be used for the manufacture of filtering articles; this has proved to be an attractive process.

Sawdust is used to absorb moisture in building walls that are exposed to water. In the manufacture of cheap wallpaper and artificial flowers it is used in the form of a fine dust. Other uses are for cementation in steel mills, for cleaning purposes in the production of gas, in the manufacture of calcium carbide and carbonundum, and, in foundries, for pickling.

Everybody knows of its application in the manufacture of powder and explosives. Further uses are for floors in gymnasiums and riding schools, for the manufacture of paper, for slippery streets in winter, and for bedding in stables. Sawdust improves soil mechanically, and, when saturated with stable manure, it also works chemically on the soil and so improves it. Sawdust is also used in sawdust mortar (for moist places) and in horticulture to protect hotbeds, etc. With proper manipulation a good wood soil, so valuable in gardening, can be obtained. In the manufacture of soap for washing and cleaning purposes sawdust is also employed.

Very promising is the manufacture of sugar and alcohol out of waste woods; but these processes are not yet far enough advanced to be of commercial value and to justify large expenditures at the same time. Finally, sawdust is the only material now used for a cheap production of oxalic acid.

DISADVANTAGES OF CHEMICALLY PURE WATER AS A BEVERAGE.

Word comes of investigations carried on by a number of French naval surgeons into the use of chemically pure water as a drink, which may be of interest to some of our readers.

To make water chemically pure it has to be distilled, and the continued use of distilled water as a beverage reduces the strength of the physical organism, because, while it is free from all germs, it contains nothing but oxygen and hydrogen. The mineral salts are left behind during the process of distillation, and the mineral salts are really indispensable.

"As long as life persists in the body," these surgeons declare, "the elimination of mineral salts goes on, and this means the rapid demineralization of the organism."

Demineralization, it is explained, leaves one's system in such a state that the natural tendency is to become tubercular. It was found that there were numerous cases of tuberculosis among the young sailors of the French navy, and this was, after long investigation by the surgeons of the navy, attributed to the demineralization of the water.

The distilled water was used in the belief that it was best for the sailors, and the naval authorities were anxious to make every condition as healthy as possible. Just now the surgeons are studying the best means of treating the distilled water used aboard the ships with mineral matter. Of course, pure water is wanted, but as conditions are now it is held that ordinary drinking water would be even better than the chemically pure, if the latter was responsible for the increase of tuberculosis in the navy.

Few people continually drink chemically pure water, and for this reason the dangers could not well be learned until this discovery was made. There are a number of ways in which the germs in water may be eliminated and at the same time the mineral salts left in the fluid. Distilled water is scarcely palatable at the best, as it is these very necessary mineral salts that make it really palatable.

An effort is being made to provide further proof of the dangers of chemically pure water as maintained by the surgeons of the French navy by means of experiments on animals.

USES AND ABUSES OF WATER FILTRATION.

At the meeting of the New England Waterworks Association, Mr. G. H. Pratt, chemist of the Rhode Island State Board of Health, read an article on the above subject, an abstract of which we give below.

In connection with the uses of filtration of water, the author would first mention a few of the conditions which call for such treatment. For many years a town or city may have been using some water of comparatively good appearance as a supply, when suddenly there appears an unusual amount of typhoid fever among the people. Investigation demonstrates that it is the water supply which is common to these cases, and bacteriological tests prove that the water of the stream is polluted. Further investigation shows that there have been some cases of typhoid in a small village upstream, which has no sewage purification, and the excreta from these cases has found its way into the water supply of the down-stream neighbor. This experience—such a common one in the case of cities and towns taking their supplies from streams which have an increasing population on the watershed—leads to a full appreciation of the need of purification, and the resulting improvement in the supply with attendant betterment of the health of the community serve as evidence of one use to which filtration is put.

Another city may be enjoying an exceptionally good health record, especially as to typhoid fever, but the presence of a large amount of organic matter, giving the water a high color and a vegetable taste, causes criticism of the supply, and, regardless of analyses as to its sanitary purity, a large number of citizens persist in the contention that the supply is not what an up-to date city should be furnishing, until finally it is decided to filter the water by mechanical filtration in order to get a water of better appearance. The criticism above referred to immediately ceases, and the people receive a practically colorless water with comparatively no taste in place of the old familiar "organic brew." Thus æsthetic reasons may in many cases be sufficient cause for filtration, and the resulting output certainly justifies its use in these cases.

Similar to the above instance, the presence of different algæ may be the cause of disagreeable odors and tastes which demand filtration by methods which, in such cases, usually require aeration in conjunction with either double slow sand filtration or mechanical filters.

Some cities or towns and numerous small private supplies have been troubled, in cases where the supply is from driven wells, by the presence of iron in the water. This iron often exists in the lower state of oxidation or ferrous condition and upon contact with the air separates from the water as a "brick dust" sediment. Such supplies as this can be purified by methods involving aeration and oxidation of the iron before filtration or in the case of smaller supplies this has been successfully done by the use of a patented double filter which utilizes sand and animal charcoal.

Many industrial processes, especially bleaching and dyeing, require water of good color, low in iron, and free from turbidity. This requirement has resulted in the installation of a large number of filter plants, and the use of filtration for these purposes has been invaluable to numerous mills of this and other countries.

A great many times filtration is resorted to largely, if not entirely, to remove turbidity from the water. This is true of many western waters.

Having thus brought out different conditions which call for the use of filtration, the author will now cite certain concrete instances of illustrations which have been made for the different reasons above mentioned, and will present results

which will show the efficiency of such plants when properly operated in improving the objectionable features which they were primarily installed to remove.

As instances of purification of supplies which have at times, prior to the use of filtration, been the cause of typhoid fever,—or, in other words, as instances to illustrate filtration for removal of bacterial pollution—we may cite Lawrence, Mass., and Providence, R.I. The Merrimac River receives sewage pollution at Lowell and at many other points above Lawrence, and its average bacteriological condition during 1910, to cite one typical year, as received on to the filters, was a total count of 9,100 bacteria per c.c., and the colon bacillus, which is taken as evidence of the presence of sewage contamination, was present in all the samples examined in 1 c.c. tests. The output from the plant (old filter) showed only 57 bacteria per c.c. and the test for B. coli communis was positive in only 8.3 per cent. of the samples examined in 1 c.c. tests. This shows a removal of 99.4 per cent. of the bacteria and a very marked improvement of the conditions as to the presence of B. coli communis.

The water supply of Providence is obtained from the Pawtuxet River, and prior to the year 1906 was used without filtration. During these years there were at least two typhoid fever epidemics which were traceable directly to contamination of the drinking supply of the city. The first was in 1882 and the second in 1888, the latter epidemic being caused by the fact that the attendants upon a case of typhoid fever had considered the river a means of quick disposal of the fecal matter of the patient.

TABLE I.
PROVIDENCE WATER SUPPLY.
(1902—1905)

Source.	No of Samples.	Average Turbidity.	Average Sediment.	Average Color.	Average Bacteria per c.c.	Remarks
Intake	96	Slight to decided	Considerable .	46	4,000	
Tap in city. .	96	Very slight to slight	Slight	41	730	After reservoir system and distribution
Per cent removal	—	Appreciable ..	Appreciable ..	10.9	81 8	

(1906—1911)

Source.	No. of Samples.	Average Turbidity.	Average Sediment.	Average Color.	Average Bacteria per c.c.	B Coli in 10c.c. tested. Per Cent. of Samples	Remarks.
Intake	144	Slight	Slight to considerable ...	48	2,525	92	
Tap in city...	144	None	None to very sight	28	60	1.7	After filtration, reservoir system and distribution
Per cent removal	—	Complete	Almost complete	41.7	97.5	—	

Agitation for purification immediately followed this last epidemic, but it was a number of years before the type of filter could be settled; but finally, in 1902, the contract was let for slow sand filters, and beginning with 1906 the city was furnished with filtered water. The results were noted at once, not so much from the standpoint of color—for as in the case with this type of filtration only a comparatively small per cent. of color is removed,—but by the freedom of the water from turbidity and sediment and by a reduction in the organic matter which had caused a marked vegetable odor and taste. Besides the visible improvement in the supply, the analytical study of the conditions before and after filtration showed the changes which were effected, and the excellent sanitary condition of the supply.

As an indication of the work which these filters have performed, I would present (Table I.) the following figures, showing the average condition of the river as to appearance, color, and bacteria for four years from 1902 to 1905 inclusive as shown by bi-monthly tests made by the Rhode Island State Board of Health, and for comparison similar figures on samples taken from a tap in the city covering the same period. These figures show that during this period the distribution system and reservoir storage effected some purification as shown by the slight improvement in the appearance, a removal of 10.9 per cent. of color and 81.8 per cent. of bacteria. Tests for B. coli communis were not made by the board at this time.

Similar figures are also presented (Table I.) showing the average condition of the river for six years subsequent to the use of filtration covering the years 1906 through 1911, and similar figures from a tap in the city for comparison. These figures show a marked improvement in the appearance of the water, a 41.7 per cent. of removal of color, as compared with only 10.9 per cent. due to the reservoir system prior to filtration, which would indicate 30.8 per cent. due to the filters themselves, and show a removal of 97.5 per cent. of the total number of bacteria present. B. coli communis was found to be present in 92.0 per cent. of the number of samples tested on the river, and in only 1.7 per cent. of those taken in the city during the filtration period, these tests being on 10 c.c. samples.

In the preceding tables one sample has been omitted in striking the bacterial averages for the tap in the city during the six years of filtration because of the fact that certain conditions which will be brought out later required the use of river water which affected that sample. The figures presented, therefore, are a true measure of the water of the city during filtration, and show the good work which has been accomplished in removing the bacterial pollution from the water.

The water supply in East Providence is taken from the Ten Mile River, which is a polluted stream receiving sewage from Attleboro, Mass. The condition of this river became such that in 1899, upon the recommendation of the State Board of Health, a mechanical filter plant was installed. The results have been highly satisfactory, showing a reduction from 8,160 bacteria per c.c. in the river to 33 per c.c. in the effluent, or a removal of 99.6 per cent., and complete removal of B. coli communis at all times. These analyses were of monthly samples taken the first eleven months of this year. In addition to this efficiency for bacterial removal, the plant at the same time reduced the color from 61 in the case of the raw water to 6 in the filtered water, or a removal of 90.1 per cent.

From the above, it has been plainly shown what can be accomplished by either slow sand filtration or mechanical filtration in removing dangers from bacterial pollution of water supplies, and it would seem to indicate very little choice between the two systems from the standpoint of removals effected, but with the advantage in favor of mechanical filtration from the standpoint of removal of color from water high in organic material. I will not attempt to go into a discussion of the relative merits of these two systems of purification, as that is not the subject of this paper, but I will simply say that each system is efficient under certain conditions, and local conditions should, in all instances, assist in the selection of one or the other method.

As an instance to illustrate the use of filters for removal of color, I would cite the case of the plant at East Warren, R.I., where during 1911 the color in the raw water averaged 74, and was reduced by the mechanical filters to 11, or a removal of 85.1 per cent. This plant is an illustration of a case where slow sand filters, while they would have delivered a sanitary output, in a short time would have experienced

trouble from algæ present, and the output would not have given satisfaction to the consumers because the water would still have been highly colored instead of being practically colorless as is the present condition.

At Newport, R.I., there is a mechanical filter plant which has been installed to serve a double purpose of removing bacterial pollution and also to remove odors due to algæ. This is an up to-date plant in every way, using a system involving aëration, coagulation, and sedimentation, followed by filtration and then disinfection of the supply with hypochlorite of lime. The color of this water is comparatively low, and the resulting output is of good appearance, when the plant is being operated up to its possibilities, and the effluent is largely free from algæ and odor troubles. Likewise, the water is reduced as to bacterial count to a point where it is practically sterile.

Next passing to the question of concrete instances of installations for the removal of iron, I would mention the the plant at Marblehead, Mass., where by the use of aëration and filtration through sand the color of the water is improved from a rusty appearance to a practically colorless water, and the iron is reduced from 4.70 parts per million to .06 parts, or a removal of 98.7 per cent. One installation has come under my personal observation where the particular apparatus above referred to, which employs a double-cylinder filter using sand and animal charcoal, showed a removal of iron 8.00 parts to .10 parts, or 98.75 per cent. removal, with accompanying improvement in the appearance of the water.

In connection with the use of filters in the purification of water for industrial purposes, I would say that I have been touch with a number of installations where mechanical filters have been installed of different types which, when properly operated under proper supervision, turn out a product which gives entire satisfaction and shows purification in every way comparable with the results above given.

In treating the second part of my subject, namely, the abuses of water filtration, I would call attention to a number of ways of abuse which might lead to criticism of the whole idea of filtration, but in citing these cases where such abuses have occurred, for obvious reasons I will refrain from naming the installations in most cases.

In the case of slow sand filtration, one would consider it an abuse to attempt to purify a water high in algæ content which would result in clogging of the beds and a general upsetting of operating conditions at the plant. Of course, double slow sand filtration, especially if in connection with aëration, would qualify this previous statement, as aëration and a pre-filter would put the water in condition where it could be handled by the secondary filters, but where aëration followed by coagulation and sedimentation and filtration by mechanical filters would obviate all of the trouble due to clogging of the beds, it would seem as if it was abusing the at times satisfactory method of slow sand filtration to attempt to handle such a water by simple slow sand filtration.

It would also seem an abuse of this method to use it in connection with filtration of highly colored water, which would subject the method to criticism on account of the unsatisfactory appearance of the output.

Another abuse of this method in connection with operation of the filters is too quick changing of rates of operation, which tends to disturb the bacterial action going on at the surface with attendant poor results from an analytical standpoint. Also attempting to overcrowd the filters by running at too high rates is a practice which is sometimes met with, which results in diminution of the efficiency of the plants.

A slow sand filtration plant which would handle a given water satisfactorily might, as was the case in Providence, be installed without covering the beds. Such an installation as this in this section of the country is certainly an abuse of the method, for the result invariably would be what was found in Providence, that as soon as a hard winter struck the plant the beds would become covered with ice and it would be impossible to get at the surface to clean without removal of the cakes of ice. This condition occurred in Providence for a short time during February, 1907, finally necessitating opening the river gate, and the use of raw water for about two weeks or so before the weather moderated and before the ice could be removed. This experience resulted in steps immediately being taken to cover the beds, and this experience should serve as a lesson against such open installations in this section of the country.

In connection with slow sand plants, it is necessary to have competent help administering the plant, and one of the easiest ways to abuse a plant is to put it into the hands of inexperienced operators.

The above remark about labor in connection with plants is especially true in the case of mechanical filters where the supervision must be particularly close and where tests for color and alkalinity must be made to regulate the doses of chemicals used.

One of these plants which has come under my observation has operated for a number of years satisfactorily, turning out a water which had given entire satisfaction in connection with work in a bleachery. When I was consulted with regard to difficulties which were occurring, I found that the only trouble was that the parties in charge did not have an understanding of the question of alkalinity control of the plant, and the residual alkalinity of the effluent had dropped to a point where the water was passing the plant at times in an acid condition, or at best with an extremely low alkalinity, resulting in after-coagulation in the vats and throughout the system. This condition had been caused by the fact that a certain mill above them had been discharging a larger amount of acid wastes in the river than at the time their formula for operating was figured for them. Not knowing how to vary the dose from time to time, they had stuck to the old formula with the resulting poor work until corrective measures were taken. The addition of alkalinity to the water put the plant back into its former good condition.

At another installation concerning which I had been consulted, I found another condition which was causing trouble. The responsible man in charge of the plant for some reason or other was assigned to night duty, and he was attempting to make his control tests for color and alkalinity at night by artificial light. This, of course, gave far from accurate results. Another trouble at this plant was that the one man was expected to operate the flow of chemicals from the tanks which were located in the pump house and at the same time attend to washing the filters in a filter house which was located about one-eighth of a mile away. This spreading out of the plant made it impossible for the lone operator to properly attend to the dosing, and the result was that the flow of chemicals varied from time to time, with resulting poor output from the plant. Here, too, I found trouble in connection with the dosing, for the formula they were using to operate by had evidently been recommended without a knowledge of the water to be handled, and they too were operating with a too low residual alkalinity.

At another plant this same trouble as to a low residual alkalinity was found to exist, and the output contained undecomposed sulphate of alumina. Investigation showed that this operator was using an indicator solution many times too

strong, and the alkalinity tests which he was obtaining were absolutely inaccurate. They also were not showing intelligence with regard to the necessity of increasing the doses of chemicals to meet varying conditions in the raw water. Corrective measures, recommended by the State Board of Health, and instruction of the operator, has resulted in this plant turning out one of the best outputs in our state at the present time.

At still another plant the biggest difficulty discovered when troubles arose seemed to be with the application of the chemicals, which in this plant required an extremely close control on account of an influence on the color of the filtered water as the residual alkalinity became too high. The engineer who was employed when this plant started was a man who had been for years pumping water out of the reservoir under the old system, and he could not be made to realize that careful supervision was necessary, and grossly neglected controlling the flow of the chemicals. These operating troubles immediately ceased when a new, competent engineer was put in charge of the plant.

The effect of an abnormal amount of organic matter or algæ in comparison with the color of the water sometimes has resulted in an under dosing with coagulant, as this additional amount of organic matter has seemed to prevent proper coagulation with resulting incomplete removal of the constituents which it was intended to remove, and the effluent has contained alumina and abnormal amounts of color and algæ. Proper dosing in view of the above-mentioned conditions has resulted in excellent work from this plant.

Another abuse is oftentimes attempting to operate a plant, with every possibility for good results, by methods which some men of limited experience may have used at some other plant, meeting entirely different conditions. Such cases have occurred under my observation, but have been capable of adjustment when instructions have been given which had in mind the type of plant and the raw water to be handled.

In connection with the operation of plants of the mechanical type, it is essential that the night man should be one who can be depended upon to stay awake, as a nap for an hour or two may result in throwing the whole operation of the plant out of adjustment for several hours. I have had my experience with this trouble.

Having thus brought out the conditions which call for filtration of water supplies and having shown the good results obtained with certain installations, I have also attempted to point out a number of ways in which filtration plants are at times abused. One or more instances of abuse are sometimes the only cases of filter plants coming to the attention of some people who immediately condemn the possibilities of the whole proposition of water purification on this meagre knowledge.

I would take this opportunity to warn you waterworks men against such conclusions from knowledge of some plant or plants which may not be doing all that has been claimed for them. I would also particularly caution that you do not take the cases of abuse which I have mentioned as indicative of any lack of confidence on my part in the ability of plants to purify water satisfactorily when the following essential points have been observed: First, have the choice of the system and the general outline and construction of the plant in the hands of competent consulting engineers who are experts in these matters; next, having obtained the plant properly constructed and designed to handle the water to be filtered, obtain the best possible men to oversee and run the plant after instruction from competent specialists, and if trouble occurs, call in advice to straighten out the difficulty instead of experimenting blindly; and last, throughout the whole operation of the plant bear in mind that you are handling an efficient machine capable of results, and not an automatic affair which can be left to its own resources.

HOT GALVANIZING.

A new hot galvanizing process has recently been patented by Professor Charles F. Burgess differing from other previous processes in that it covers the use of an alloy of zinc and iron for coating iron or steel. The alloy is composed of about 92 per cent. of zinc and 8 per cent. of iron, and is prepared in a powdered or granulated form. The alloy is applied to the iron and steel in a similar manner to the well-known process of sherardizing.

Arthur D. Little, Inc., of Boston, who touch upon this matter in their report as official chemists to the American Institute of Metals, say that it is claimed by the inventor that the finished coat is dense and silver white in color and electro-positive to iron, but less so than pure zinc, with the result that it does not corrode as rapidly as zinc, and yet at the same time protects the iron or steel equally well.

CONDENSER TUBES.

A number of interesting papers have been presented before the British Institute of Metals, among which might be mentioned "The Corrosion of Brass Condenser Tubes" by Mr. Paul T. Bruhl. This paper is the result of a thorough study of this troublesome problem, and brings out certain very interesting conclusions arrived at by the author. "In this connection attention should be called," says Carl F. Woods, of the staff of Arthur D. Little, Inc., chemists and engineers, of Boston, "to the proceedings and the report of the corrosion committee of the Institute, which was opened a year ago with a view to carrying out an exhaustive and authentic research on the corrosion of brass and bronze. The committee have decided to erect in Liverpool a plant in which the conditions of marine condenser service should be as closely imitated as possible. The plant is to consist essentially of four cast-iron tubes, each fitted with tube-plates to carry twelve condenser tubes, these iron tubes representing four small independent condensers. The condensers will be connected direct to the exhaust of a small engine, which in turn will drive a circulating and vacuum pump for circulating sea water through the condensers. Each condenser will be fitted with the same kind of tubes, and the committee has decided for the first set that one condenser shall be equipped with the so-called "Admiralty" mixture with a tube plate of naval brass, the equipment being carried out with the same extreme care insisted upon by the "Admiralty" practice. The second condenser will represent the best class of commercial practice, the tubes being 70-30 mixture and the plates of yellow metal. The exact equipment of the other two condensers had not been decided upon at the time of the committees progress report, but they will be compositions representative of commercial practice. The results obtained from careful experiments carried out in this way should be of the utmost value, as it should be possible to practically duplicate service conditions and at the same time to control the various conflicting conditions in such a way as to arrive at definite, well-founded conclusions

POWER SUPPLY ON THE RAND.

By A. E. Hadley, M.I.E.E.*

[NOTE.—The Victoria Falls and Transvaal Company, Limited, was formed at the end of 1906, with the object of supplying power in South Africa and Rhodesia, and of acquiring the concessional rights to develop the Victoria Falls. Mr. Hadley read a paper on this power development work recently before the Institution of Electrical Engineers, Great Britain, and it is an abstract of this paper which we publish below.—Ed.].

Under the original proposal a supply to the Rand was to be given partly by transmitting power from the Victoria Falls, 700 miles distant, and partly by steam generating stations located on the reef. The author became associated with the company shortly after its formation, and after its original proposal had been modified through giving up the plan to supply part of the requirements of the Rand with power from the Falls.

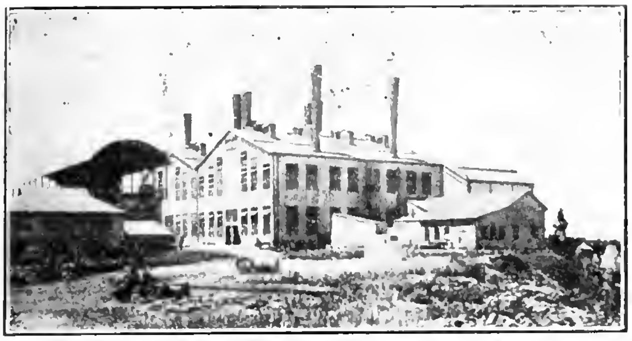


Fig. 1.—Exterior of Generating Station at Simmerpan.

The great demand for power on the Witwatersrand has arisen through the extraordinarily successful development of the gold mines on the reef, which, although only discovered in 1886, now produce 33 per cent. of the world's output of gold. Further, it is estimated by the leaders of the gold-mining industry that the work of raising gold will still be in progress on the Rand 100 years hence.

Turning for a moment to the history of electric power on the Rand, a few details will be of interest. Siemens and Halske were the first to obtain a concession in 1894, and formed the Rand Central Electric Works, Limited, in 1895, which had a plant aggregating 3,200 kw. capacity in 1906. Another concession was obtained by the Simmer & Jack mine in 1897, from which the General Electric Power Company was estblished in 1906 with plant having a capacity of 2,500 kw. In 1905 Messrs. Lewis & Marks, having in view the possibility of supplying the Rand from their coal-fields at Vereeniging, 35 miles south, commenced obtaining way-leaves for a pole line, while certain European manufacturing companies sent out representatives to report on the prospects.

The Victoria Falls Company ultimately took over the two existing supply companies in 1907, and purchased the Vereeniging wayleaves from Messrs. Lewis & Marks, at the same time entering into an agreement with them for the right to establish a power station at Vereeniging. In 1907, pending the installation of modern plant, a supply totalling 4,000 kw. was given from the existing steam stations which had been purchased.

As soon as it was appreciated that a cheap power supply was available the mining groups entered into contracts with the company, and the demands for power have since increased so quickly that it has throughout been the greatest difficulty for the company to raise capital and install plant rapidly enough to satisfy the demand.

In 1908 the largest group of mines, viz., that controlled by the Rand Mines, Limited, and Messrs. Eckstein & Company, decided to change over their mines to electric driving. In addition to the supply of electricity to this group of mines, the conditions called for the supply of compressed air for working the rock drills.

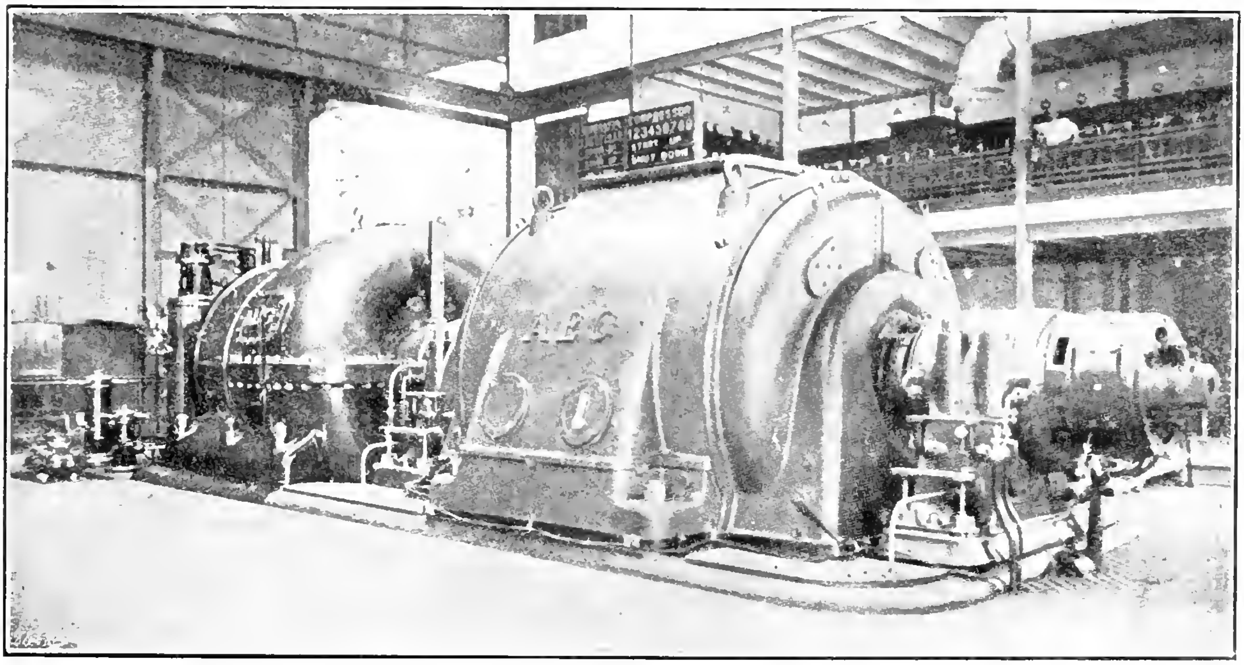

Fig. 2.—Turbo-Generator of 12,000 k.v.a.

The peak load of the combined undertaking has reached 88,000 kw., and the sales average 1,350,000 units per day. These figures include the sales of compressed air to 10 mines. The air units represent practically the same amount of energy as if these 10 mines had converted their compressors to electric drive and purchased electricity. When the further

* Managing Director of the Victoria Falls and Transvaal Power Company.

demands for power which have already been notified are met by the plant now on order, the sales will reach 2,000,000 units daily. The monthly load factor, based on the hour of maximum output, varies from 70 to 74 per cent.

The supply is furnished to all mining consumers at 2,100 volts and 525 volts. The necessary step-down transformers and switchgear are provided by the power company, while the consumer supplies the sub-station building and pays the power company a sum equal to 2 per cent. of the power bill to cover the losses in the step-down transformers.

The standard price in mining contracts covering not less than 12 years is 0.525d. per unit, as long as the monthly load-factor is above 70 per cent., the load-factor being based on the hour of maximum consumption. This price is subject to periodical revision depending upon the cost of production, and further, a participation with the consumers in the profits of the business after a due return has been paid on capital is also provided for. In case of failure of supply the consumers are entitled to a payment from the power company of 7s. per hour for each 100-kw. put out of commission.

The introduction of these prices on the Rand has reduced the cost of power to the mines by 40 per cent., and has reduced the cost of production of gold by an amount varying from 6d. to 1s. per ton of ore milled. It has further resulted in considerable saving of capital expenditure on plant, which in the case of a new mine may amount to £100,000.

The area over which a power supply has to be given lies within a strip about two miles broad and stretching 50 miles from east to west. The total power used by the mines at the present time is estimated at about 400,000 horse-power.

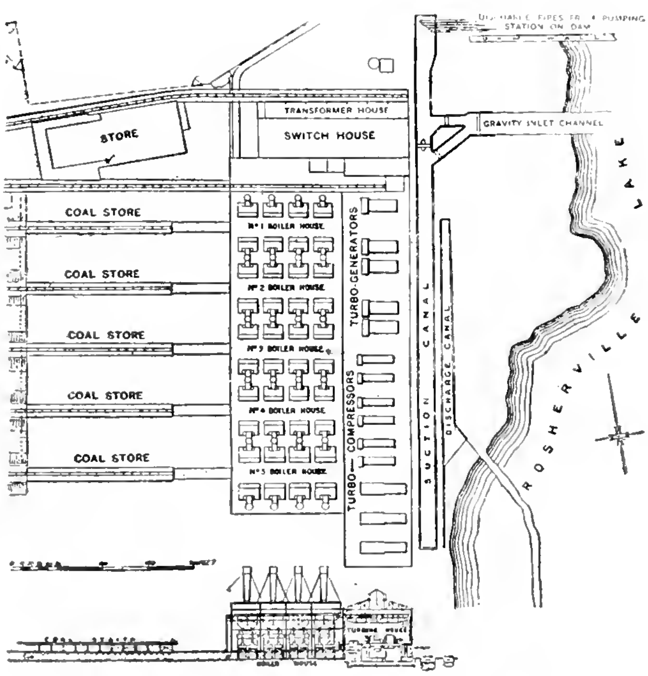

Fig. 3.—Plan of Rosherville Power Station.

Power plants aggregating nearly 180,000 kw. have been installed in, or are under construction for, the stations enumerated in the table given at the end of this article. They are set out in the order in which they were built.

At Robinson Central air station there are also six electrically driven air compressors, each of 3,500-kw. capacity.

At all stations steam turbo-electric generating sets are employed, and produce three-phase energy at 50 cycles. Step-up transformers raise the generator pressure to 40,000, 20,000 or 10,000 volts, and their interposition gives additional security to the machines against pressure rises. This method, in which the generator voltage is optional, gives the further advantage of enabling the stators to be constructed with the bar winding having one bar per slot.

The main system of transmission is effected by means of 40,000-volt overhead lines stretching practically the whole length of the reef. At the present time, however, the western extremity is working as a 20,000-volt distribution line. Where the load is most dense the transmission consists of two rows of towers, each arranged to carry two circuits.

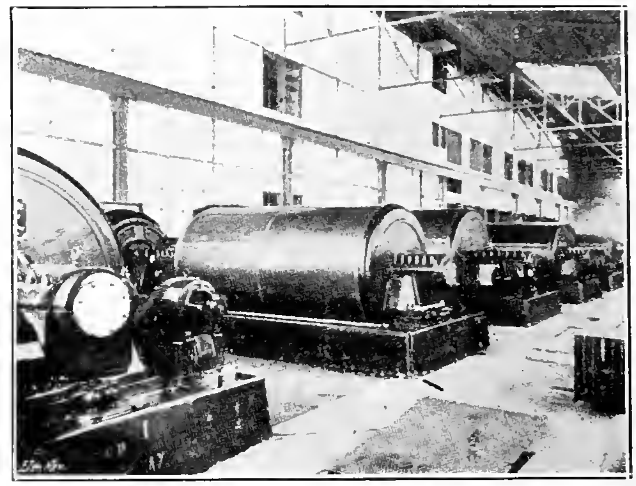

Fig. 4.—Air Compressors at Robinson Central Deep.

The 40,000-volt transmission system is fed at Brakpan, Simmer Pan, Rosherville, and at Robinson Central, where the supply from the Vereeniging station joins the reef. In addition to these distribution stations the transmission lines pass through two further distributing centres at Hurcules to the east and Bantjes to the west. From these six points distribution networks, laid out as ring mains, supply the various sub-stations on the mines. The three eastern distribution stations supply the system through 10,000-volt overhead lines. The central portion of the area is served by an underground 20,000-volt cable system.

The Vereeniging station is connected to the Rand by an 80,000-volt line approximately 35 miles long, terminating at the Robinson Central distribution station, where the pressure is transformed to either 40,000 or 20,000 volts, these pressures being also coupled together through transformers aggregating 16,000 k.v.a.

All transmission and distribution circuits, with the exception of the long-distance 80,000-volt lines, are equipped with the Merz-Price balanced relay system for automatic switch control, without which a reliable supply on the ring-main system could not have been given, and the more expensive radial type of network would have been necessitated. This balanced relay system is also employed for the protection of all transformers and for the large generators. The pilot wires for operating this system on the 40,000-volt transmission lines are combined with telephone circuits in a lead covered cable suspended overhead, while on all distribution networks (both overhead and underground) combined pilot and telephone cables are laid underground.

A special feature of the lay-out of the telephone system is the arrangement whereby the control of all switching and the control and regulation of load, voltage, power factor, and other operating conditions, are in the hands of the control department.

One control engineer or load dispatcher is responsible for all routine switching and linking carried out at any point

on the electrical system during his shift, and under the regulations no switching can be carried out without his consent. The load dispatcher, as soon as any switching has been carried out, adjusts a large diagram in the control room so that it shows every connection on the system.

When the contract with the Rand Mines, Limited, was concluded the site for the station was selected at the Rosherville Dam, which is the largest lake on the Rand. This station will shortly have a capacity of nearly 100,000 kw. of plant installed. After the new extensions are completed the turbine room will be 450 feet long and 75 feet wide, and there will be five right-angle boiler bays, each containing eight boilers. The general lay-out is shown in Fig. 3.

The coal-storage arrangements are very complete, the coal being discharged from a height of 14 feet through the floors of 40 ton railway trucks into outside storage bunkers, under which coal conveyers are arranged. The whole structure is open, as roofing is unnecessary, owing to the favorable climatic conditions.

The conveyers, each capable of dealing with 40 tons of coal per hour, run in tunnels under the external coal store, and are fed with coal by gravity through shoots from the coal pile above. These conveyers are kept running practically continuously, allowing the internal coal bunkers in the boiler house to be of small capacity. An automatic tip is fitted over the bunkers, which tips the conveyer buckets when the coal in any particular bunker has fallen below a certain level. Weighing machines are installed in the conveyer tunnels, and the coal is weighed as it passes in the conveyer buckets.

The ashes are discharged from the rear of the stokers into hand trucks in the basement, where natives push the loaded trucks out and attach them to a motor-operated rope haulage leading to the ash dump. The question of removing these ashes by suction is at present under consideration.

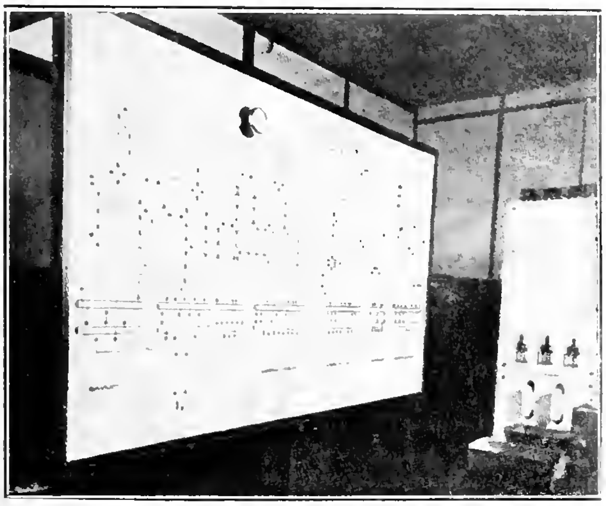

Fig. 5.—Load Dispatcher's Diagram.

The class of coal burnt at this and other Rand stations is mostly the small coal from the collieries in the Middelburg district, 60 miles distant, mixed with a proportion of the duff produced by the coal-cutters. The coal has an average calorific value of about 11,000 B.th.u. per lb.

The large percentage of ash, viz., 18 to 25 per cent. of the coal, and the high load factor at which the plant is operated, necessitated a combination of boiler, superheater and economizer that would give the highest possible efficiency; the high cost of white labor, and the inefficiency of that of the native, also required that the plant should be mechanically operated.

In view of these considerations, and the great cost of constructional work in South Africa, the injector system of induced draught originally devised by Mr. Prat has been adopted in all the power stations. The system has been found to give the utmost satisfaction.

In the lay-out employed, adjacent boiler units are connected to a common ejector chimney, the top of which is 90 feet above the boiler-house floor. An electrically driven rotary fan, capable of developing 75 h.p., blows cold air

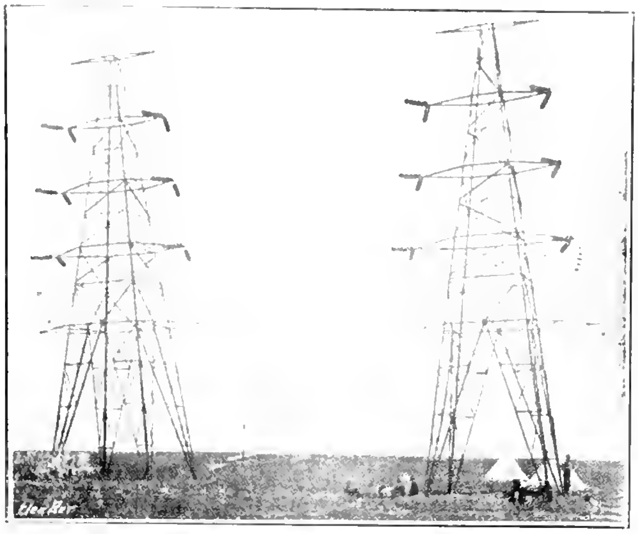

Fig. 6.—Double Tower Line at 80,000 Volts, and Construction Camp.

through the ejector situated in the chimney, thereby producing the necessary suction in the flues, and a draught of about 1 inch is usually employed.

With this arrangement great flexibility in the boiler house is obtained, and by the use of a torpedo-shaped damper in the air pipe regulating the pressure of the air jet, the duty of the boiler unit can be easily regulated to suit fluctuations in the load. The plant is absolutely smokeless, and it is difficult by looking at the ejector chimneys from outside the station to tell which boilers are at work.

The boiler unit selected is the Babcock & Wilcox marine type, fitted with chain-grate stokers, each having an integral superheater and economizer. The boilers are arranged in two rows in each boiler house, with a central and common firing floor. Each boiler has a rated capacity of 32,000 lb. of steam per hour at a pressure of 220 lb. with a temperature of feed water of 100 deg. Fahr., and is capable of producing 38,000 lb. of steam without undue forcing. The heating surface of the boiler is 5,520 square feet, of the superheater 1,720 square feet, and of the economizer 2,200 square feet. A six-hour test on one of the boiler units gave a combined efficiency of boiler, superheater, and economizer of 80 per cent.

The turbine room at present contains five turbo-generators each of 12,000 k.v.a. (Fig. 2) and six steam compressors each having an input of 3,500 kw.; three more steam compressors each taking 7,030 kw. are also being installed. The turbines are of the A.E.G.-Curtis horizontal type, having one high-pressure wheel with three rims of blades. The admission pressure at the intake nozzles is brought down from 220 lb. at a temperature of 300°—350° C. to about 20 lb. with a superheat of about 20° C. In the low-pressure portion of the turbine, the steam is expanded through 12 stages. Both

hand and motor regulation of the speed are arranged for. The total weight of a 12,000-k.v.a. turbine set, including condenser and pumps, is 370 tons.

The stators of each of the six-pole generators are bar wound, having one bar per slot. The machines running at 1,000 r.p.m. produce 50-cycle three-phase energy at 5,000 volts, which is stepped up to either 10,000, 20,000, or 40,000 volts, by transformers directly connected with the stator terminals.

The rotor coils are lined with metal casings before being attached to the rotor by dovetailed grooves and wedges. The rotor carries a ventilating fan at each end. The frequent dust storms in South Africa charge the air with heavy particles which might prove dangerous in the ventilation of the machines, consequently each machine is provided with an air filter having an effective surface of fireproof cloth of 8,000 square feet. Each turbine set is provided with a direct-driven exciter, while a stand-by supply is also available from a motor-generator and battery.

The condensers have a cooling surface of 17,750 square feet; each set has a centrifugal circulating pump of about 663,000 gallons per hour capacity, and a centrifugal air pump, both connected on one shaft and driven direct by a steam turbine. The exhaust from the auxiliary turbine is taken to the middle stage of the main turbine, where the remaining energy in the steam is utilized down to the vacuum of the condenser.

The water for the condensers and compressor jackets is taken from the lake through a channel excavated along the front of the station, and is discharged into a second canal placed alongside the intake; this canal delivers the warm water to the lake at a point as far from the intake as possible. Under normal conditions of water levels the intake water flows by gravity into the service canal, but in order to deal with periods when the water in the lake may be low, a pumping station has been erected half-way along the dam wall at the deepest part of the lake.

The boiler feed pumps are of the turbine-driven centrifugal type, and are installed in the turbine room. With the exception of certain electrically-driven bearing-cooling pumps, all auxiliaries are turbine-driven.

The generator transformers are connected by cables to their corresponding generators, and are each of 12,500-k.v.a. capacity. Where larger transformers have been required, as for the last two sets at Vereeniging, two transformers for each machine have been installed. The transformers at Rosherville are of the shell type and water-cooled, the windings nearest the terminals being specially insulated to withstand between adjacent turns a pressure of 25,000 volts for five minutes. A test pressure of 160,000 volts was applied to the whole of the windings. The weight of each transformer complete without oil, is 50 tons; the oil itself weighs 21 tons.

The steam turbo-compressors at Rosherville are similar to the motor-driven compressors at Robinson Central, and are each designed to deal with 22,000 cubic feet of free air per minute with an outlet pressure of 9 atmospheres (absolute). The power required on the shaft is, roughly, 3,500 kw. In the case of electrically driven sets at Robinson Central each unit is divided into two halves on separate shafts, each motor having a capacity of about 2,000 k.v.a., and being designed to operate at full load at a leading power factor of 85 per cent. The sets run at 3,000 r.p.m. The steam-driven compressors are arranged in two sections on the same shaft with an intercooler between them. The cooling water required for the jackets of the compressor and intercooler amounts to about 40,000 gallons per hour. The air leaves the compressor at a temperature of about 70 deg. C.

Between the compressor and the pipe line an automatic non-return valve is fitted, which allows a compressor to drop out to atmosphere when its pressure falls below that of the air system.

By the use of the rotary compressors the air entering the pipe system is kept entirely free from oil and other impurities liable to be introduced into the air system when piston compressors are employed. The speed regulation of the steam turbo-compressors is automatically controlled by the pressure in the air pipes. The regulation of the electrically driven compressors at Robinson Central is effected by throttling the intake. The weight of a turbine-driven compressor, condenser, and pumps is 180 tons.

The switchgear is laid out in a building at the southern end of the station, and the step-up transformers are in cubicles arranged along the outer side of the switch-house. The last-mentioned is constructed with four floors: the upper floor contains the lightning-arrester gear, the third floor the bus-bars, the second floor the 40,000 and 20,000-volt oil switches, whilst the lower floor is occupied with cableways and pipe passages. Duplicate bus-bars are installed for both the 40,000 and 20,000-volt systems, the various oil switches being provided with knife selector switches to connect to either bus-bar. The 40,000 and 20,000-volt systems are connected together through coupling transformers. The switches consist of three single-phase coupled switches operated from a remote-control board.

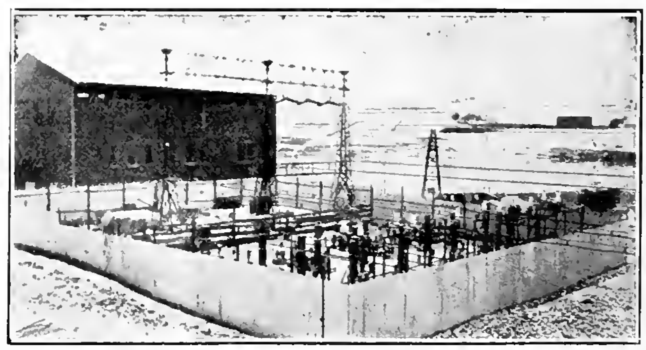

Fig. 7.—Lightning Arresters, Etc., at End of 80,000-volt Line.

Since the Rosherville station came into commercial service, troubles have been experienced owing to failures of switches on short-circuit. When the Brakpan and Simmerpan stations were started to supply the 40,000-volt transmission and also the 10,000-volt local lines, their total capacity was 24,000 kw., and no trouble was experienced when a short-circuit occurred on the system. When, by the addition of Rosherville, the system grew to 60,000 and 70,000-kw. capacity, switch breakdowns occurred, conclusively proving that no apparatus was available which could be relied upon to interrupt the immense rush of current occurring on short-circuit.

Some serious line interruptions have in the past been caused by the wilful throwing of bare wires over the lines. When this form of short-circuit has occurred near a power station, apparatus has usually been lost.

Dynamos running at a high speed have a low internal reactance. The step-down transformers in the present case were designed with a low reactance to give good regulation, so that probably the total reactance in circuit on a short-circuit was about 7 or 8 per cent. The momentary rush of energy on short-circuit could therefore reach the tremendous

proportions of 500,000—700,000 kw. No oil switch, as at present designed, could interrupt this rush of power unassisted. The intensely hot gases formed by the arc, after rising through the oil, come into contact with the air and cause an explosion, which, more often than not, is productive of a switch failure.

About the time that this trouble became apparent on the Rand, exactly the same difficulty was being experienced on stations of similar large output in America, and the problem was vigorously tackled over there. Many methods have been tried at Niagara, Chicago, and other places, and it has become generally recognized that it is necessary to insert additional reactances in order to limit the rush of energy on short-circuit. In certain cases this precaution has proved entirely satisfactory. In others additional methods for assisting the oil switch have been necessary; such as (1) sectionalizing the system on to separate bus-bars and limiting the amount of machinery that would be affected by one short-circuit; (2) the placing of two switches in series timed so that one opens first and inserts a non-inductive resistance, the circuit being actually broken by the second switch; (3) the use of a special type of switch having two moving systems, one of which first introduces reactances, and the other then breaks the circuit.

These methods have been tried on the Rand. The earthing of the neutral through a resistance has proved most valuable, as more than 90 per cent. of the faults start as faults to earth. At Rosherville and Vereeniging reactances having a value of about 6 per cent. have been installed between the dynamos and the step-up transformers. The latest practice is to design both generators and transformers required for power service with large internal reactances.

At Vereeniging and at the Rand end of the 80,000-volt line two systems of switching have been installed. On the first two Vereeniging machines two switches are employed in series, one introducing a non-inductive resistance; while on the last two machines, both of which have not yet been put into service, a two-movement reactance switch is being installed. This switch is constructed on the lines of an oil-break switch, but is provided with a second pair of contacts for the final break. The separation of the first pair of contacts introduces two reactances placed centrally one on each terminal bushing inside the oil tank, and the second pair of contacts finally breaks the circuit.

At some early date the system will also be sectionalized in order to reduce the rush of power on short-circuit, and in doing so reactances of relatively large value can be inserted between sections in those cases where it is not economical to separate adjacent sections permanently.

This problem of switchgear for dealing with enormous rushes of power has proved one of the most difficult that has been encountered so far on the Rand and also in America. It has not yet been finally solved, nor have switches been standardized which are capable of dealing unassisted with these exceptionally severe service conditions. These remarks on switchgear apply not only to the central stations, but also to the distribution stations, and in a less degree to the consumers' sub-stations.

The electrical supply at 2,000 volts and 550 volts to the consumers' premises is effected from step-down transformer stations, which are built by the consumers, but are equipped with switchgear and transformers by the power company. (Fig. 8). There are 60 of these consumers' sub-stations connected to the system, and their individual capacity varies from 10,000 k.v.a. to 2,000 k.v.a., the normal size being 5,000 k.v.a.

The standard sizes of consumers' transformers are 1,000, 500 and 250 k.v.a., designed with the primary windings arranged for either 20,000 or 10,000 volts. A temperature rise of 40 deg. C. is allowed above an air temperature of 40 deg. C. The windings near the outgoing terminals will stand a pressure of 15,000 volts between adjacent turns. The high-tension windings are tested to the secondary windings and core with a pressure of 40,000 volts, and the insulators with 60,000 volts. The transformers have been supplied by Messrs. Siemens, the Allgemeine Elektricitäts Gesellschaft, and the Westinghouse Company.

The transformers are exported filled with oil, thereby reducing the cost of transport and dispensing with the necessity of drying out after erection. In order to allow for the expansion and contraction of the oil each transformer tank is connected with a second smaller tank fixed on the wall of the sub-station. This expansion tank is fitted with a vertical vent-pipe, so that only a small surface of oil is in contact with the air, and by this means sludging is prevented. Each

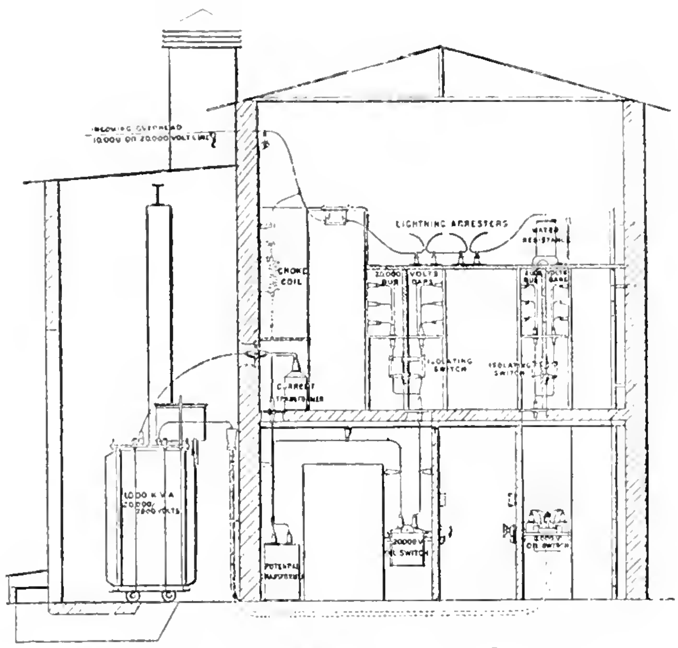

Fig. 8.—Section of Standard Type of Consumers' Sub-station.

sub-station chamber has a short stack, which induces a natural draught and provides effectual ventilation. Double bus-bars are provided for each voltage. The high-tension and low-tension switchgear in each sub-station is arranged in different chambers with a central operating passage between containing no "live" material. The "live" chambers are locked, and stringent regulations as to the possession of the keys ensure that no unauthorized person can obtain access; in no case is one man allowed to enter alone. The total capacity of the transformers in operation, including generator transformers and coupling transformers, is unusually large, amounting at the present time to 450,000 k.v.a.; but this will be increased to 508,600 k.v.a. when the transformers delivered and on order are brought into commission.

The company realize the importance of welfare work and its influence on the conditions of the life of the staff. They give a generous support to recreation and sport, and facilitate in every way the promotion of social intercourse among all classes of the employees.

Some 60 residences and quarters have been built by the company at the various power stations, and at each station

a boarding house and recreation rooms are provided. Generally speaking, the conditions of life compare very favorably with those of an engineer on the mines. A fleet of 14 motor-cars is maintained in constant service for the use of those officers and engineers of the company whose duties necessitate visiting the different parts of the system. A special department handles the entire transport of materials, and employs constantly two motor-lorries and 50 mules and horses.

Name of station.	Total capacity of electric generating plant installed.	Steam-driven air compressors installed.	Extensions in progress.
Brakpan	Two 3,000-kw. sets	—	—
Simmerpan	Six 3,000-kw. sets	—	—
Rosherville	Five 10,000-kw. sets	Six 3,500-kw. machines	Three 7,000-kw. steam-driven air compressors
Vereeniging	Four 10,000-kw. sets	—	—
Extensions in 1913.	—	—	Two 10,000-kw. sets
——	114,000 kw.	21,000 kw.	41,000 kw.

Total capacity of plant installed and in progress, 176.000 kw.

ELEVATORS ON PACIFIC COAST

Prince Rupert is to make a bid for the wheat traffic that will come to the Pacific coast from the prairie provinces. Mr. J. E. Dalrymple, third vice-president of the Grand Trunk Pacific, has announced to the board of trade of the northern city, that an elevator with a capacity of ten million bushels is to be erected on the townsite and that construction will start shortly. This is really the first definite announcement of the construction of big wheat elevator on the Canadian Pacific coast, with the intention of looking after the trade that is expected. There has been talk of many in and around Vancouver and New Westminster. Mr. Dalrymple's statement is definite, and shows that the Grand Trunk Pacific will have some of the trade from Western Alberta when its line is completed. The Canadian Pacific Railway at this point will also get busy when the time comes, so it can be taken as granted that elevators will be erected in the neighborhood of Burrard Inlet in due course. Officials of the railway have stated the traffic will be taken care of when it arises, and naturally they will do what they can to increase business.

A number of leading officers of the Great Northern and Northern Pacific Railways have been on the coast during the past week. A stated time is now given when the Northern Pacific will have its own tracks into Vancouver, that is, as far as Cloverdale on the south side of the Fraser River, thence by Great Northern Rails into Vancouver. A joint depot with the Great Northern is spoken of. There has also been a slight hint that the Great Northern would link with the Canadian Northern in a big depot at the head of False Creek. The suggestion is reasonable, for if two depots are erected they will be quite close together, and one large depot would serve the purpose better. But, as one of the officials remarked, it is three years yet before filling in operations will be completed, so there is plenty of time to figure out about the depot.

SOME QUALIFICATIONS REQUIRED OF AN ENGINEER.

By Prof. E. Brydone-Jack, B.A., C.E.*

The following extracts from an article in the Manitoba Engineer for March, 1913, will no doubt be read with interest, especially by the younger men in the profession:

The opportunities opening up to young engineers to-day are more numerous and varied than ever before. We find them taking up the business part of their profession as well as the technical part and holding positions as managers, superintendents, presidents, etc., of large corporations.

If the engineer is to take advantage of these opportunities, how must he be prepared, what are the necessary qualifications in order to attain success?

Evidently knowledge of theory is not the only qualification required, knowledge of practice is not the only qualification required. It is essential that the engineer should possess the knowledge of both theory and practice, but in addition to these he must have character and judgment.

Character and judgment are qualities which determine an engineer's advancement just as much as and perhaps more than his technical knowledge. It is no uncommon sight to see men with an excellent knowledge of both theory and practice occupying subordinate positions, while those with less knowledge but with more executive ability are placed over them.

The engineer is measured and advanced according to his efficiency. True efficiency can only be obtained by a combination of technical knowledge, character and judgment. It is essential that the engineer should learn thoroughly the fundamental principles upon which is based the particular branch of engineering which he is to follow, and that he should have the power to apply them intelligently and correctly. He should be able to observe accurately and reason logically from premises gained by observation or otherwise. His character should be such that his word and honesty can always be relied upon and that he should realize the ethical principles which should govern a man's acts in this world and which should regulate his conduct towards his fellowmen.

His judgment should in all cases be unbiased and depend entirely upon the facts presented. This implies reasoning power and ability to reach logical conclusions.

These qualifications may perhaps be best summed up in the "Specifications for a Good Engineer" in Chief Engineer Starling's report to the Mississippi Levee Commissioners, which are as follows:

"A good engineer must be of inflexible integrity, sober, truthful, accurate, resolute, discreet, of cool and sound judgment, must have command of his temper, must have courage to resist and repel attempts at intimidation, a firmness that is proof against solicitation, flattery or improper bias of any kind, must take an interest in his work, must be energetic, quick to decide, prompt to act, must be fair and impartial as a judge on the bench, must have experience in his work and in dealing with men, which implies some maturity of years, must have business habits and knowledge of accounts. Men who combine these qualities are not to be picked up every day. Still, they can be found. But they are greatly in demand, and when found, they are worth their price; rather they are beyond price, and their value cannot be estimated in dollars."

CONTENTS OF THIS ISSUE.

THE METER AS A FACTOR IN ELIMINATION OF WATER WASTE.

Within the past few years a phase of municipal engineering that has attracted more than passing interest is that which has to do with the control of public water supply for domestic purposes. In some cases municipalities are supplied by private companies, while in others the system is controlled by the municipality and run as one of its branches of the administration. In either case the problem of supplying the water to each individual on an equitable and fair basis is a very real one, and it would seem that the only satisfactory solution of the problem is the adoption of the meter system.

The waste of water that goes on in many municipalities in many cases is appalling, and in some instances positively criminal. Statistics show that the amount of water wasted during the winter months with the sole object of preventing freezing of pipes is equal to six gallons per day per capita for the entire year. While this waste is allowed to continue it most effectively prevents the enlargement of works and the attachment of new sources of supply at great cost, for almost all statistics show that could the waste of public water be brought down to its minimum, the question of an adequate supply dependent upon enlarged uses and the increase of population would practically be adjusted.

While there have been many arguments against the more general introduction of the meter system, such as references to the unlimited supply of water and its effect upon health, etc., it is a fact that the meter system stands to-day an unqualified success and the only logical solution of this very vexed question.

Looked at from the viewpoint of economics the usefulness of the water meter is unquestioned. Its value in this direction has been demonstrated time and time again. On the other hand, there are some cities in which influences are constantly at work looking to the prevention of their introduction. This will probably always be the case, but the fact remains that the only sensible way to check this enormous waste is by the introduction of the water meter.

THE ENGINEER AND HIS READING.

While, perhaps, the engineer is not more negligent about what he reads regarding what is going on in his profession than many other classes, the fact remains that too many engineers leave our universities with the impression that while at university it was proper he should read, and read much, when he gets out into the field it is work that is called for.

In this day of rapid changes the realm of engineering is no exception, and it behooves the technically trained man to see to it that he does not neglect the opportunities which are afforded him of securing information generally covering the latest practice in all branches of engineering, and particularly the one in which he is most interested. In fact, he is likely to be a better engineer if some of his time is given over to the study of other phases of engineering than the one in which he is specifically interested at the moment.

In order to keep himself posted concerning developments going on in engineering practice, he should most assuredly, in addition to relying on his text-books, spend some time in reading the current technical papers. He should come to realize the importance of knowing what the man is doing who is engaged in the same class of work as himself; in other words, he must modernize his

practice; be aware of the progress his profession is making, if he is to be in a position to adopt new ideas and new processes and apply them in his own daily work. He will get such service by a careful reading of the leading technical journals covering the profession of engineering. While a man may succeed, and succeed to a very unusual degree as an engineer without the help which the technical press can afford him, it is fair to assume, other things being equal, that the man who is posted in relation to his work, due to a careful study of technical journals, which show him how the other man is attacking and accomplishing certain results, will make an even greater success.

It is particularly important that the younger engineer just beginning his career make it a practice to read such papers as most adequately cover the particular branch of engineering he is to specialize in, and, where necessary, make a practice of clipping those articles which are of particular interest to him, and which are likely to prove of value in the days which are to come, and which will doubtless have a direct bearing upon his work.

THE WATERWORKS OF CANADA.

Through the courtesy of the Commission of Conservation we have received a copy of a report compiled by Leo. G. Denis, Hydro-Electric engineer of the Commission of Conservation, in which is given a very large amount of valuable data covering the waterworks systems now in existence throughout the Dominion of Canada. The report includes detailed information concerning something like 360 plants, as well as a table showing the number of sewage disposal plants in Canada, which information has been tabulated from data compiled by the committee on sewage disposal of the Canadian Society of Civil Engineers, 1911-1912. The information relating to each waterworks is given under the name of the city, town or village, it being arranged alphabetically under each province, while the provinces are arranged geographically from east to west. The information given has been arranged in a very concise and convenient form, and it is hoped that it will prove valuable to all who are interested in water supply generally. Not only that, but it will also help those directly connected with waterworks systems to become better acquainted with conditions relating to other plants than their own. The report contains a number of valuable charts summarizing the information gathered, and altogether is a very valuable addition to the statistical literature covering this very important phase of the civil engineer's work.

EDITORIAL COMMENT.

A most interesting and valuable symposium on the subject of expert advice comes to this office in the form of a verbatim report of a discussion held at a meeting of the American Institute of Consulting Engineers when that subject was the topic. That the need of better and more intelligent methods of securing expert evidence is called for is evident, and the subject is one that should have great interest for the engineering profession. Those interested may secure a copy of the brochure by addressing a letter to Eugene W. Stern, secretary American Institute of Consulting Engineers, 101 Park Avenue, New York.

With the announcement from Ottawa this week that tenders for the building of the first section of the Welland Canal will probably be called for toward the end of this month, one is struck with the fact that Canada is more and more being confronted with engineering projects that a few years ago would have been considered unlikely. The writer recalls being in the office a very few years ago of one of, if not perhaps the largest, engineering contractor in Great Britain, a man who was at the head of a contracting organization whose activities extend to almost every part of the civilized world. He was asked why it was he gave little or no attention to Canada as a field of operation. He answered to the effect that Canada was yet of insufficient importance to justify his giving it his attention owing to the absence of large projects of an engineering nature. It is interesting to note that that particular firm, as well as two or three others in the same class, now have very aggressive organizations in Canada and are actively bidding for work here. It is pleasant to record a fact such as this. Large work means large responsibility. Our various engineering schools throughout the Dominion will no doubt rise to the occasion and see to it that the type of engineer turned out is equal to the challenge which this day of larger things in engineering in Canada gives him.

* * * *

We beg to acknowledge the receipt of the first issue of the journal of the Regina Engineering Society. This publication, as is stated in the introduction, "symbolizes the spirit and enterprise of the West having for its object the welding of the engineers of the province into a body which shall jealously uphold 'the dignity of the profession.'" To all this *The Canadian Engineer* says "Amen," and hopes that the expectations of the gentlemen responsible for the birth of the Regina Engineering Society and those who are more actively connected with its work will realize their object, which is a laudable one. The journal contains a resumé of the beginnings of this society, the first meeting of which was convened on Tuesday, April 2nd, 1912, and at which fifty engineers were present. During the year there have been about one dozen papers presented, the titles of which indicate the broad scope in engineering which the membership of this society represents. We congratulate the society on its progress, and hope that it will in every sense of the word be successful. It is interesting to note that the following papers have been promised for presentation before the society during the coming months: "Side Hill Grades," by E. W. Murray, B.A.Sc.; "Power and Intensive Cultivation," by A. E. Eisenach; "Compressed Air Water Supply," by F. McArthur, B.Sc.; "Scientific Methods of Designing Streets," by J. R. Ellis; "The Law of Contracts and Specifications," by C. C. Owen, and "Power House Economy," by J. A. Gibson.

On representations made by the Canadian Manufacturers' Association as to the material desired to be submitted, and that more time is required to collect and codify it to the best advantage, the Board of Railway Commissioners has determined that the consideration of reciprocal demurrage and its suggested application in Canada, also what is known as the "Average Demurrage" Plan, should stand until a special hearing to be held at the Central Station Building, Ottawa, Ont., on Monday, June 16th next. Boards of Trade interested may send in their data from time to time as they desire, and present their cases entirely by written arguments.

STOPPING PLANES IN REINFORCED CONCRETE.*

By Edward J. Stead.†

It appears to the writer, from considerable experience of reinforced concrete construction, that insufficient consideration is as a rule given to the determination of positions of stopping planes in this class of work.

Beams and Slabs.—In concreting beam and slab work, it is a common practice to fill up the beam forms to the level of the under side of the slab; then, at a later stage of the work, to follow over with the slab concreting separately. During the interval, the surface of exposed concrete receives more or less injury from dirt, etc., and it has frequently been noticed that the shear reinforcement gets flattened down and knocked out of shape. These circumstances result in a plane of weakness as regards horizontal shearing on the line a—b in Fig. 1. It has further been observed that the stopping planes in the slab concreting are often made vertical over the longitudinal centre lines of beams, as at c—d in Fig. 1.

In this type of design the beams are in general calculated as T-beams; and, notwithstanding the fact that many successful contracts have been carried out in the manner indicated, it is submitted that it is undesirable to make temporary joints in the position shown. No matter how carefully the surfaces are cleaned and roughened, the homogeneity so greatly desired cannot be secured.

To obtain the full value of the area of concrete in compression—i.e., that portion of the beam proper which lies above the neutral axis, together with the width of the slab

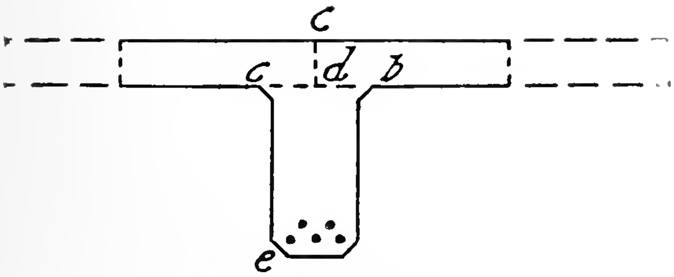

Fig. 1.—Plane Over Beam Centre, Resulting in Probable Weakness in Slab.

acting with it—stopping planes should be excluded, as far as practicable, from that area. Unless the vertical reinforcements in the beams maintain their intended shapes and positions, are rigidly attached to the tensile reinforcement, and well concreted into the compression area, the resulting construction approaches that of a rectangular beam of depth a—e with the slab resting upon it, and the strength will be considerably less than the designer intended.

As a matter of practical construction, stopping planes must occur somewhere in the concrete; and it is suggested that in the case of beams in one direction only—i.e., no secondary beams—the better practice is to cast the beam and slab in one operation, as shown in Fig. 2, in which the dotted lines f—g and h—j represent joint lines parallel with the beams and at the centres of the slabs between them. There can be no serious objection to the joint through the slab, as it is at right angles to the direction of the main reinforcement, the bars of which, being continuous over two or more beams, ensure full tensile strength being availabl[e]. A temporary face-board would be necessary to keep a vertical face of concrete to join up against on resuming. The upper part of the slab being in compression, the action under loading will be simply pressure on the two concrete faces, and the shearing stress at the joint will be nil.

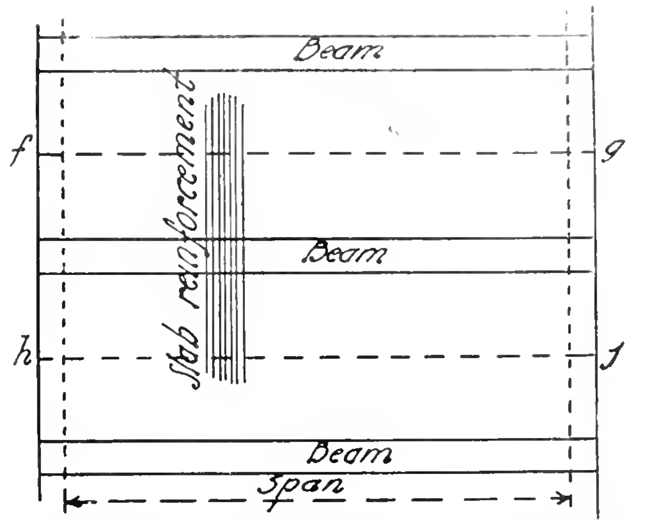

Fig. 2.—Beams Running in One Direction Only—Beams and Slabs Cast as Units—Planes Midway Between Beams.

In constructing larger floors where there are both main and secondary beams, a somewhat similar method is desirable. For the purpose of illustration, a floor has been assumed as in Fig. 3, where the main beams, supported at intervals by columns, run the short way of the building; and between the main beams are the secondary beams, with a slab over all.

Here the main beams and column connections demand special notice, and from theoretical considerations the concreting would be most advantageously carried out in bays across the short way of the building, each bay comprising a main beam and portions of the attached secondary beams and slabs, the joint lines being along the centre lines of slabs and parallel to the main beams, as shown by the broken lines a—a. Complete homogeneity would thus be assured to the main beams and the portions of the slab acting therewith as a T-beam; there would be no break in the work or around

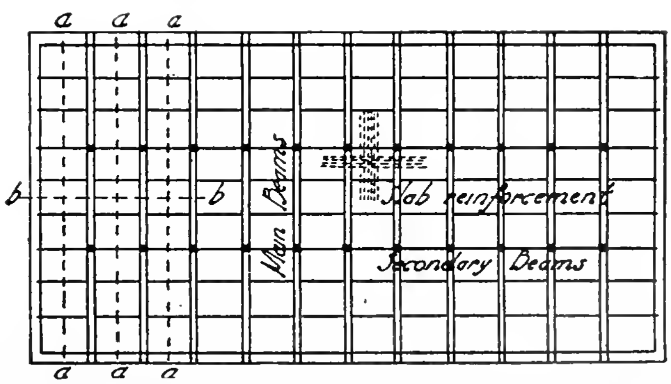

Fig. 3.—Main Beams With Column Supports; Second Beams—Planes on Centre Lines of Slabs, Parallel to Main Beams; also at Centre of Middle Span.

the column heads; and so far as the secondary beams are concerned, the stopping planes would be in the most suitable positions—viz., at the centre of the span and at right angles to the direction of the beam.

---

* From Concrete and Constructional Engineering.

† Associate Member, British Institution of Civil Engineers.

Assuming, however, that the size of the building is such that the volume of concrete in one bay, as indicated, is too great to be put in without a break, it will be necessary, in order to reduce the amount of work to be done in one operation, to make stopping planes through the main beams. The first point then calling for notice is the necessity for avoiding a break at the points of inflexion (which are at approximately a distance of one-fourth the span from the supports), on account of the shearing action at such points. A stopping plane could most advantageously be made at the centre of the middle span—i.e.. in the line b—b.

In no case should concreting be stopped in beams or slabs where shearing stress is likely to be great, as at a point near the supports or under a heavy concentrated load.

It is necessary to fix the whole of the reinforcement in beams before concreting is commenced; but in the case of slabs a common practice is to lay the bars down a few at a time as the concreting proceeds. The adoption of the stopping planes advocated above necessitates the fixing of the slab bars in advance of the concreting—a decided gain as regards accuracy of spacing and the ultimate strength of the work.

Columns.—In general, stopping planes in columns present no difficulty, as they are usually concreted for the full height between floors at one operation. Even if this does not occur, provided the concrete is temporarily left with a horizontal surface, and kept clean and free from foreign matter, no weakness is incurred, as the joint will be at right angles to the pressure upon it.

Arches.—The stopping planes in concreting arches may occur, according to the magnitude of the arch, either longitudinally or transversely. In each case, both the upper and lower reinforcements should be placed and fixed securely in position prior to commencing concreting. Where possible, a strip the full thickness of the arch should be concreted from abutment to abutment in one operation, the temporary joint being made against a profile erected on the laggings, in the case of longitudinal reinforcement only, or, in the case of mesh reinforcement, by short boards set vertically between the meshes, as shown in Fig. 4.

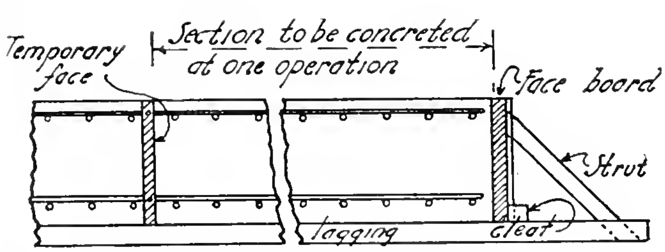

Fig. 4.—Use of Temporary Board Facing in Longitudinal Concreting of Arch.

In concreting sections of the arch transversely, the stopping planes should be at right angles to the line of pressure, or, for all practical purposes, perpendicular to the curve of the arch at the point; and, where possible, it is preferable to concrete a section the full width of the bridge at one operation. The temporary joint in this case will be made against a straight shutter of such depth as to be a very easy fit between the upper and lower reinforcement, such shutter being slipped in from the ends and temporarily secured at the proper angle. On recommencing, the shutter will be drawn out, the face-boards fixed, and concreting proceeded with. The formation of a stopping plane of this description is shown in Fig. 5.

By careful consideration beforehand, the positions of stopping planes ought to be determined and then worked to. Too much emphasis cannot be laid upon the necessity for

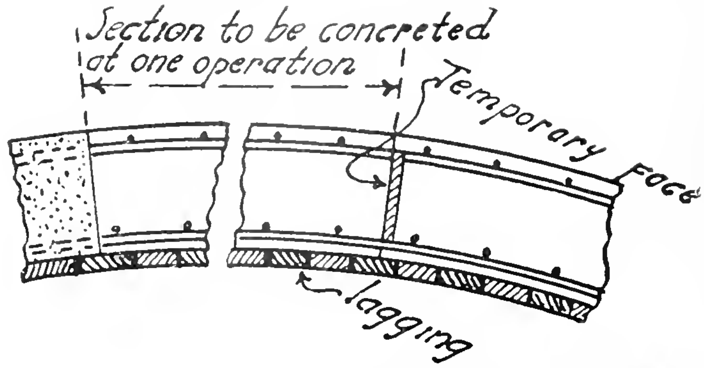

Fig. 5.—Formation of Temporary Joint in Concreting an Arch Transversely.

thoroughly cleaning, roughening, and laying thick grout upon all stopping plane surfaces when concreting is recommenced.

TRADES UNIONISM FOR PROFESSIONS.

By A. B. Howes.

In the study of the history of commerce, trade and manufacture we find that at an early period the advantage of dividing labor into special and distinct branches was realized, and as civilization progressed the adoption of this principle became one of its distinguishing features, and in many ways tended to its advancement. . . . In course of time, as trades became separate and distinct from one another, we find, on the part of the members of each trade, an increasing tendency to unite for the purpose of controlling their particular trade. . . .

Although it is rather a contradictory use of the word, we find that in the past unions among members of a particular profession were, in certain cases, recognized by the Legislature, and were given statutory control over the members of that profession. . . .

That registration is the outcome of modern requirements is abundantly shown by the action of the Colonies in requiring the registration of professions which in the Old Country can be carried on by anyone, although in all probability before many years have elapsed this wise rule will be general in Great Britain as well.

To summarize, the advantages of registration appear to be these:—

The standardization of the qualification of members, at all events as regards a minimum qualification.

Powers of discipline over the members in regard to their professional conduct; powers which are especially effective where such conduct is not within the purview of the law.

Regulation of fees paid to members of the profession.

A closer union in the profession by reason of these three principal advantages.

A general uplifting of the tone and character of the profession by reason of its recognized disciplinary organization.

[Extracts from an interesting paper which Mr. Howes recently read before Quantity Surveyors' Association.]

MAINTENANCE OF SHEET ASPHALT PAVEMENTS.*

By Francis P. Smith, C.E.†

The proper maintenance of an asphalt pavement involves the making of such repairs to it from time to time as are necessary in order that it may continue to render efficient service as a safe and smooth roadway or street.

The deterioration which eventually renders these repairs necessary commences as soon as the pavement is laid and may be broadly classified under the following heads:—

1. Defects due to the wear and tear of traffic.
2. Defects caused by the deterioration, through age and exposure of the bituminous cementing material used.
3. Defects in construction.

Traffic Deterioration.—Under traffic the surface of the pavement is abraded and gradually wears off and the mineral particles exposed on the top are more or less crushed and broken. Where these particles are large, this crushing action is plainly noticeable, but with the smaller particles of sand it is hard to detect it. Under heavy traffic and unfavorable weather conditions, these crushed grains become active centres of disintegration. The crushed particles are not bound together by the asphalt cement and are soon swept away. The holes thus made in the pavement serve to retain the moisture and the edges of the holes are eventually more or less broken down, thus enlarging the hole. This condition reproduced all over the surface tends to make it wear away much more rapidly than would otherwise be the case. The effect of this action, which at first glance appears trival, has been so well established by years of investigation and experience that it has become axiomatic in the paving industry that the heavier the traffic the finer must be the particles composing the mineral aggregate. In hot weather, when the pavement is plastic, the abrasion of the surface is much less than in cold weather, when the pavement is hard and possesses practically no plasticity. In hot weather the caulks on horses' shoes sometimes mark up the pavement to a very considerable extent, but the subsequent action of vehicular traffic wears these marks out almost completely. Nevertheless, in a community unaccustomed to sheet asphalt pavements, the appearance of these caulk marks in a new pavement is always regarded as an ominous sign presaging its speedy destruction and failure. As a matter of fact, if the pavement, especially when newly laid, were not soft enough to show these marks it would be an almost infallible sign that the asphalt cement used in it was too hard and that the total life of the pavement would be less than if a softer asphalt cement had been used. Traffic on a pavement always compresses it and increases its density, and for this reason a two-year-old pavement will always mark up less than a new one. The pressure per square inch exerted by the comparatively narrow tire of a heavily loaded vehicle is much greater than that exerted by the heaviest steam roller used in the laying of sheet asphalt pavements. Even if this were not the case, the kneading action produced by narrow tires passing many times over the surface would always give greater compression than could be obtained by the action of the broad tires of a steam roller.

When the traffic is confined to a comparatively narrow space and is always in the same direction, a distinct pushing force is exerted on the pavement. Whenever the pavement lacks inherent stability, due to an improper mineral aggregate or bitumen which is lacking in cementing value from natural causes or the rotting action of gas or water, or a combination of these defects, very distinct waves or bumps will be produced by the action of heavy traffic. These waves sometimes occur in recently laid pavements in which the asphalt cement used was of the highest quality, but in such cases will usually be confined to a few places. Investigation will almost always show defective binder in these spots, or too soft an asphalt cement, or too great a thickness of pavement owing to an error in the grade of the concrete. A paving mixture, designed to have proper stability when laid two inches thick, will often fail in this respect when laid four inches thick, which is the explanation in the case last cited. Too soft an asphalt cement will also reduce the stability of a pavement. Once these waves appear, they are aggravated by traffic passing over them. The wheel of each vehicle rises to the crest of the wave and then drops down with considerable force into the adjacent depression. The plastic pavement in this way is continually displaced at the low spots and shoved up at the high spots until in many instances the concrete will be exposed at the bottom of the depression. Similar depressions are produced by setting manholes too high above the surrounding pavement. Vehicles drop off these high manhole covers onto the pavement and soon pound it out of place. It is better to set all manholes slightly below the grade established for the finished pavement.

Waves are much less liable to appear in those portions of the pavement which are subjected to cross traffic; i.e., in which the traffic does not always move in the same direction. This is usually the case at street intersections, and, if properly constructed, the pavement in these locations almost always lasts longer than in any other part of the street. It has been seriously suggested that in order to increase the effective life of pavements, the direction of the traffic in the afternoon should be the reverse of that in the morning, but the resulting confusion would probably more than offset the gain from such a procedure. Car tracks in a street paved with sheet asphalt may cause the pavement to deteriorate very rapidly. Unless the rails are very heavy and laid on an adequate foundation, they will vibrate excessively when cars pass over them. This is especially the case where tracks designed for light city or town cars are subsequently called upon to carry heavier cars or cars of the interurban type. Not only will the vibration be excessive, but the rails will frequently sink below the level of the pavement and leave depressions where the water will collect. To prevent the vibration from being communicated directly to the sheet asphalt, rows of paving blocks or bricks are frequently placed along the rails, although in many cases the sheet asphalt is brought up directly to the rails. When the vibration is excessive, the sheet asphalt pavement crumbles or cracks in a very short time and leaves an opening for surface water to enter between the wearing surface and the concrete foundation, thus permitting the rotting action elsewhere described to take place.

Effect of Ageing and Exposure.—All bituminous materials used in paving work deteriorate upon exposure to the elements and to the rotting action of escaping gas, water and street liquids. The lighter oils contained in them gradually volatilize, thus hardening the remaining bitumen. As the hardening process goes on, the pavement loses its plasticity and wears away with increased rapidity. Eventually the bitumen loses its elasticity and the pavement cracks. The edges of these cracks crumble away and the cracks become sufficiently wide to be plainly felt by vehicles passing over them. The bumping action previously described in connection with waviness is produced and adds to the

* Abstract of lecture delivered at Columbia University.

† Chemical Engineer, New York City.

rapidity with which crumbling takes place. In order to guard against this and prolong the effective life of the pavement, the asphalt cement used in its construction is made as soft as possible without rendering the pavement too mushy when new. The extent to which this can be carried depends upon the grading and character of the sand employed. With a well-graded sharp sand and plenty of filler, a much softer asphalt cement can be used than with a poorly graded or rounded sand. This is due to the greater inherent stability of the former type of sand. It is obvious that a mineral aggregate which when dry strongly resists displacement will permit the use of a comparatively soft asphalt cement. Modern traffic conditions have in this particular respect come to the aid of the pavement makers. Automobiles in their passage over the pavement are continually dropping a certain amount of oil on its surface which is very evenly distributed by the large number of vehicles passing over it. This oil is gradually absorbed by the pavement and thus softens the bitumen and counteracts to a large extent the hardening action of time upon it. This is very clearly shown in a certain pavement in Chicago, which, prior to the passage of any considerable number of automobiles over it, some five years ago was so hard and badly cracked as to have practically reached its limit of usefulness. The street in question subsequently developed into an automobile centre with the result that the pavement was softened up by the dropping of oil upon it to such an extent that it is still giving satisfactory service. Fifth Avenue, New York City, is a somewhat similar case.

Some asphalts are more easily rotted by water action than are others. With such asphalts it is more than ever necessary to make the pavement as dense as possible to prevent the water from getting into it. Generally speaking, with all asphalts the wetter the climatic or other conditions, the denser and richer in bitumen should the mixture be made.

The action of water upon a pavement may take place from the surface downward or from the bottom upward. The latter action is the more serious and the harder to guard against. The top surface is always compressed to its maximum density by the action of traffic, and if it has sufficient crown and grade to let the water run off and is kept clean so that it will not be covered by a layer of wet mud for long periods, but little deterioration will take place. Where water is allowed to remain in the gutters, the rotting will frequently be very rapid and this will be still more marked if, as in some towns, the dirty wash water from houses is discharged into the gutters. Too frequent washing of a pavement with water at a high pressure is also bad, as the abrasive action of such a jet is very considerable and acts in the same way as the stream from a hydraulic nozzle. In a number of cases water finds its way between the wearing surface of the pavement and the concrete foundation. This may be due to the geological formation of the subsoil strata (and it must be remembered that concrete is not waterproof, especially the type used for foundation work) or the water works its way down between car tracks and the abutting pavement, or through faulty gutter construction, etc. Under such conditions, it has little or no chance to evaporate or drain off and attacks the pavement at its weakest point, i.e., where the compression is the least. It gradually destroys the life of the bitumen and renders it incapable of cementing the grains of sand together. This action progresses upward through the pavement and in some cases is not apparent until only a top shell of good pavement remains. Depending upon the conditions, this action usually manifests itself by a shoving and waviness of the pavement at the point where the rotting has taken place. Owing to the loss of the cementing power of the bitumen, the stability of the pavement has been lowered so that it can no longer withstand the shoving action of traffic previously described. If the pavement is cut through at this point, the white sand grains will be plainly apparent and the whole mass can be readily disintegrated between the fingers. As soon as the rotting action reaches the surface, the pavement is quickly worn away by traffic and a hole is produced.

Gas leaks produce a very similar result and the gas sometimes travels a long distance from the point of leakage before it actually comes in contact with the pavement.

Another cause for the deterioration of sheet asphalt pavement is lack of traffic. Pavements laid on outlying residence streets and culs-de-sac with little or no traffic, crack much more quickly than if they were subjected to a moderate traffic, which appears to be necessary to keep the life in the pavement. This is probably due to the fact that the surface is not in such cases kept at the maximum density by the action of traffic and gradually becomes porous, thus facilitating the evaporation of the lighter oils and also to the fact that the kneading action of traffic, like the continual use of a rubber band, tends to keep the life, so to speak, in the bitumen, and equalizes the stresses set up by contraction and expansion.

Defects in Construction.—These may perhaps be more clearly understood by a general discussion of the principles involved and the correct way of carrying them out and coincidentally calling attention to the particular defects arising from marked departures from standard practice.

Unless the foundation is rigid and of sufficient strength to carry the weight of the traffic passing over the finished pavement, no sheet asphalt wearing surface will give satisfactory service. Being plastic at all normal temperatures, the wearing surface will not bridge over any depressions formed by the sinking or failure of the foundation, but will sink with it. The principles governing good foundation work and design need not be considered here except to say that the sub-grade must be well rolled and compacted in the first place and that good concrete of sufficient strength and thickness should then be put in place and allowed to set before any binder or wearing surface is put upon it. Assuming that the sub-grade has been properly rolled and that the concrete is of the proper thickness and quality, the first point of importance is to see that it is laid to grade. If it is too high in places, the thickness of the binder and wearing surface must be reduced in order that the surface of the finished pavement may conform to the established grade. Any marked diminution in the thickness of the wearing surface will, under heavy traffic, considerably reduce the life of the pavement. On the other hand, if the concrete is laid too low, the thickness of the binder and wearing surface will have to be increased. Within limits, this is not objectionable if the increased thickness is not carried to such an extent as to affect the stability of the pavement, otherwise it will tend to roll and push out of shape under traffic, as previously described. It is usually considered better practice to leave the surface of the finished concrete somewhat rough in order that the binder may key into these depressions and still further resist the shoving action of traffic. After the concrete has been put in place, ample time should be allowed for setting, and this will vary with the weather conditions. Concrete laid in freezing weather will apparently set up when in reality it has frozen. When the hot binder and surface mixture are placed on frozen concrete, the latter is thawed by the action of the heat and becomes mushy and has not sufficient strength to support the weight of the steam roller. Under such circumstances it is impossible to properly compress the hot mixture. In addition to this, the water set free by the thawing of the concrete is forced into

the mass of hot material and more or less of it remains entrained in the mass.

In most forms of construction, a binder is laid directly on top of the concrete, although this is sometimes omitted and a paint consisting of asphalt dissolved in naphtha is applied directly to the dry surface of the concrete and the wearing mixture laid directly on this. It goes without saying that the surface of the concrete should be dry and swept clean before the binder is laid upon it. The binder consists of a mixture of broken stone, preferably the run of the crusher with all particles smaller than 1/10 of an inch in diameter excluded and usually not exceeding 1½ inches in its largest dimension, mixed with sufficient asphalt cement to firmly bind the particles together. Sometimes sand or gravel is added to this mixture to increase its density. Where stone chiefly of the larger sizes is used without the addition of any sand or gravel, it is termed an open binder. The denser mixture produced by the use of better graded stone and the addition of sand or gravel is called close binder. The best modern practice calls for the use of the tight binder as it gives a much firmer foundation for the wearing surface and will not be broken up and loosened from the concrete by the passage over it of the teams hauling the hot surface mixture. The stone should be hard and clean; i.e., free from fine adhering particles of dust or dirt, in order that the asphalt cement may firmly adhere to it and the mineral aggregate must be heated to the proper temperature before mixing it with the hot asphalt cement. Stone which is too cold or damp will not coat properly in the mixer and binder which is too cold can not be given sufficient compression upon the street. If the stone is too hot, it will burn the asphalt cement and harden it so that the binder will be brittle and difficult to compress. Sufficient asphalt cement should be added to thoroughly coat each particle of the mineral aggregate and make a mass which, when rolled, will be sufficiently sticky to adhere to the concrete satisfactorily.

A close binder properly made and laid will be superior in many respects to the mixtures which have been laid on a large number of country highways and will carry a fair amount of traffic for a considerable time without suffering any serious damage. Poor binder will break up very easily—sometimes it can be kicked up, and the hauling of the hot surface mixture over it will damage it very seriously. Surface mixture laid on a binder of this kind which has been badly broken up might almost as well be laid on loose broken stone and will not give satisfactory service under heavy traffic. The binder should, of course, be thoroughly compressed with a steam roller before laying the wearing surface on it. Lack of compression will produce an unsatisfactory foundation for the wearing surface, and, as previously mentioned, binder which is too cold or made with too hard an asphalt cement or an insufficient quantity of asphalt cement can not be properly compressed into a dense, tough mass. In hauling the binder to the street over long distances or in very cold weather, it may become chilled below the danger point. During the hauling process a certain amount of surplus asphalt cement usually drains off the stone and accumulates on the bottom of the cart or wagon. If these excessively rich portions be laid on the street, what are called rich or fat spots in the binder course will be produced. As the name implies, these are places carrying an excess of asphalt cement. If these are permitted to remain, the surplus asphalt cement will be absorbed by the hot surface mixture when it is placed over them. This will make a soft spot in the finished pavement which will be displaced by traffic and eventually produce a hole or depression in the pavement. They should, therefore, be cut out and replaced with normal binder.

Before laying the surface mixture on the finished binder course, the latter should be dry and swept clean of dirt; otherwise the layer of wearing surface will not adhere properly to it. The principles governing the manufacture of a suitable surface mixture are similar to those involved in the binder course, except that owing to the heavier duty which it is called upon to perform they are carried further. The particles of the mineral aggregate must be sufficiently hard and fine to carry the traffic without being fractured. They must be of such a character that the asphalt cement will firmly adhere to them and they must be so graded in size as to produce a pavement of sufficient stability and density for the purpose intended. The asphalt cement must be of the proper consistency and the heating and mixing must be so conducted as to produce the best possible mixture. When delivered upon the street, the mixture should be of such a temperature that it can be properly compressed and should be evenly spread by means of hot iron rakes. In many cases the loads of hot surface mixture are dumped directly upon the spot over which they are to be spread. This is bad practice, as the men trample upon it while shovelling and raking it and the rakes do not thoroughly loosen up this trampled material when passing over and through it. Although the mixture is raked to a uniform surface and apparently even thickness before it is rolled, those portions which have been trampled on before and during raking are really covered with a greater quantity of surface mixture than those portions which have not been trampled on and which are covered wholly with what might be termed loose or fluffy mixture. When the roller has completed its work there will, therefore, be a slight unevenness in the finished surface. Under light traffic this would make no appreciable difference, but under very heavy traffic the slight pounding action resulting from this condition would be detrimental and lead to uneven wear of the pavement. Proper and thorough compression of the finished mixture is very essential as this produces a pavement which in its earliest stages is fit to sustain the heaviest traffic. It is always questionable whether portions which are very lacking in compression will be ground out or eventually consolidated. Under unfavorable conditions the chances are strongly in favor of their being ground out. In those portions of the pavement which are inaccessible to the roller, compression is effected by the use of hot smoothers or tampers, or both. If properly handled, the desired results will be obtained, but if used too hot, they will burn the pavement and cause it to scale or grind out. Hot smoothers particularly are dangerous tools to put in the hands of incompetent or careless workmen.

Extreme care should be taken to insure a proper union between the surface laid on successive days. The first loads laid in the morning at the termination of the previous day's work should be a little hotter than normal so that the hot mixture may soften the cold edge of the pavement and bond perfectly to it. The joint should be bevelled and freshly cut away unless the rope joint or a similar method is employed.

The practice of painting the edge of the joint with hot asphalt cement is not to be recommended, as, unless extreme care is exercised, too much asphalt cement will be used and that portion of the pavement will be too rich in bitumen and consequently softer than the rest, which will result in uneven wear and possibly shoving. Great care should be taken not to have any hump or depression when the joint is made. A brief summary of the chief defects and failures met with in practice and the contributing causes is given below.

Cracking.—Cracking of the concrete base—Hardening of the asphalt cement through age—Use of too hard an asphalt cement—Use of an unsuitable asphalt cement—Too

little bitumen in the surface mixture—Insufficient compression—Lack of traffic—Improperly constructed joints—Extreme and sudden changes in temperature—Vibration of street car rails.

Disintegration of Surface.—Defective base—Unsuitable mineral aggregate—Insufficient bitumen in mixture—Insufficient compression—Use of too hard an asphalt cement—Use of overheated mixture—Burning due to use of excessively hot smoothers—Action of water—Action of illuminating gas.

Waviness.—Use of an unsuitable sand—Use of too soft an asphalt cement—Unstable binder—Lack of stability in mixture—Too great a thickness of mixture—Projecting manholes—Action of water—Action of illuminating gas—Uneven raking—Too much bitumen in mixture—Excessively heavy traffic in one direction over a limited area.

Scaling.—Too coarse a mineral aggregate—Too hard an asphalt cement—Action of water—Accumulation of mud—Too little bitumen—Excessively heavy traffic.

Repairing.—This should be carried on within a reasonable time after defects first make their appearance. If this is neglected, deterioration proceeds much more rapidly than would otherwise be the case. Holes and depressions are increased in size by the passage of vehicles over them and water accumulates in them, accelerating disintegration.

Two distinct methods of repairing are in general use: 1, The pavement is cut out and removed down to the concrete and replaced with new binder and surface.

2, The upper portion of the surface is first heated by suitable appliances and a thin layer of it removed by rakes and shovels. Immediately thereafter and while the remaining pavement is still warm, a comparatively thin layer of new hot surface mixture is spread over it and raked and compressed in the usual manner followed in the construction of new pavements.

The first method is so simple that but little description of it would appear to be necessary. The defective pavement is cut up into pieces sufficiently small to facilitate its removal and pried up with crowbars if necessary. The adjacent edges of the old pavement are trimmed up with an asphalt cutter and sparingly painted with hot asphalt cement to insure a proper bond between the old and new portions. Under favorable conditions and when the pavement being repaired is not too old and hard, this painting with asphalt cement may well be omitted. All loose debris is removed down to the concrete and a new binder course and wearing surface is then laid in exactly the same manner as when constructing a new pavement. This method should always be employed in filling up holes and depressions or wherever the defective pavement is in such shape as to necessitate its complete removal, as in the case of rotting from the bottom upward and waviness, defective binder or foundation, etc.

The second, or surface heater method of repair, is conducted as follows: The surface heater is placed over the defective pavement and put in operation. Superheated steam, hot air or flame is then brought in contact with the surface and is allowed to remain there until the pavement has been softened to the required depth, usually from ¾ to 1 inch. The heater is then withdrawn and placed on the next spot to be repaired and the burned material completely removed. The space thus left is immediately filled with new hot surface mixture which is spread, raked and finished in the usual manner. Care must be taken to completely remove all burnt material down to such a depth that the new surface after compression will be not less than ¾ inch in thickness except in a very limited number of cases. Skin patching of less depth than this has not proven satisfactory. In order that repairs made by this method will give satisfactory service, it is essential that the remainder of the old pavement which serves as a foundation should be sound and in good condition and free from water rotting. It is not applicable to the class of repairs rendered necessary by defective binder, or foundation, or water, or gas rotting. When it becomes necessary to re-surface, wholly or in part, a pavement which has become too hard through age to give satisfactory service, the surface heater method gives very good results and is much cheaper than a complete removal of the old pavement down to the concrete. By applying the hot new surface mixture to the remaining portion of the old pavement while the latter is still hot from the action of the heater, a satisfactory union between the old and new work can readily be obtained, provided that the hardening of the old pavement has not been allowed to proceed so far that it is impossible to soften it by the application of heat. Cracks may in most cases be more successfully repaired by this method than is possible in any other way. The repairing of cracks satisfactorily is a very difficult matter. If they are cut out and new material put in, this results in the formation of two joints approximately parallel to the original crack. If the pavement being repaired is old and hard, it is difficult to establish a good bond between the old and new portions, and unless this is accomplished, two cracks will shortly appear where only one existed before. This is especially the case where long cracks make their appearance at considerable intervals and in many instances these had better be left until they become sufficiently wide or numerous to render more or less extensive re-surfacing necessary at these places where they occur.

ROAD WORK IN SASKATCHEWAN FOR 1913.

In preparation for the large programme of work in the construction and improvement of public highways in the province for this year, for which $1,200,000 was voted at the last session of the Legislature, the Board of Highway Commissioners is sending out to all the municipalities in the province a copy of the regulations of the Board regarding assistance to municipalities on highway improvement, together with several blank application forms for use of the municipal councils in applying for assistance.

In those places where an improvement can be definitely described in some form or specifications so that a definite standard to work to can be set and a reasonable agreement made between a contractor and the authorities, so that each party will know definitely what is required, the contract system is the best. Most of the work of road improvement will not conform to these conditions, however, and in such cases gangs under a properly qualified and reliable overseer or foreman is the most satisfactory organization.

The worst of all systems is where councillors order out taxpayers to work out their taxes on the road with no proper provision nor systematic selection of roads that should be improved, and with no attempt made to finish the work started if the taxes run out before this is accomplished.

The Board will be much encouraged to grant large amounts of assistance where the organization approaches the best system. Where municipalities are not organized or properly equipped to economically or satisfactorily carry out road improvement the Board would rather undertake the expenditure of what funds they have available in such municipalities through their own organization.

DUCTILITY TESTS OF RAIL STEEL AND SEGREGATION OF STEEL INGOTS.

The following is an abstract of a paper recently read before the annual meeting of the American Institute of Mining Engineers by P. H. Dudley on the "Piping and Segregation of Steel Ingots and Ductility Tests of Rail Steel."

Bessemer steel of 0.10 to 0.15 per cent. of carbon, for splice-bars, spikes and tie-plates, rises in setting and is cast in bottle-mouthed moulds, which must be capped to prevent an overflow from the top. This grade of steel rises in the moulds and makes a longer ingot than the volume of molten steel when first teemed. The ingots, when allowed to cool and then cut open, show, particularly in the upper part, large occluded blowholes, which, when they are not oxidized or do not contain foreign matter, weld more or less completely if the steel is rolled or forged at about 1,100 degs. C.; and it is in this way that the blowholes are closed in the low-carbon steels.

Boiler-plate and fire-box steel often contains more or less minute laminations, which are the remains of small blowholes forming after the setting metal has reached a pasty condition. The blowholes in the low-carbon steels have not been prevented by using deoxidizers, though the ingots are slightly improved so far as the soundness of the steel is concerned. This grade of steel also rises in the moulds in setting.

Ingots of rail steel containing 0.50 to 0.75 per cent. of carbon are of entirely different character when they are sufficiently deoxidized to form comparatively pure steel, as a well-defined shrinkage cavity forms. This important fact should be remembered in discussing rail-steel, for the greater the degree of its deoxidation, the larger will be the difference between the enclosed volume of hot fluid metal in the mould and the cooler or solidified metal, and proportionately still less will be the volume, should the ingot be allowed to become cold before equalizing the heat and rolling. We must deal with three conditions or stages of the steel:—(1) The greater volume of hot molten metal. (2) The less volume of hot set metal. (3) The least volume of cold metal in the dimensions of the rail sections.

The exterior blowholes in the outside walls of the ingots can be prevented from forming by sufficient deoxidizers, as silicon, ferro-titanium, or compounds of these, and aluminum. The last has been extensively used, but all of its oxidation products do not always escape from the metal, and it should not be used when the steel is to be subjected to the present heavy steel wheel-loads. The silicon content for rail steel now ranges from 0.10 to 0.20 per cent., to make it sound and prevent small blowholes from forming in the setting metal. When sufficient deoxidizers are used to efficiently purify the steel, then, as must be expected, a small cavity starts to form in the top under the cap of the ingot in the setting steel, as already described, and its development should be retarded by stripping the ingot and promptly charging it into the reheating furnace.

Rail ingots are no longer allowed to become cold before being charged into the reheating furnaces for blooming. The size and length of the ingots must be taken into consideration, for in those ingots of which the length is from four to five times the width of the base, the steel will set on the interior walls long before their vertical shrinkage of hot to cold metal has occurred, and this increased length will add proportionately to the volume of the interior piping or shrinkage cavity.

Ingot Size in Relation to Rail Sizes.—It was customary a few years ago to teem ingots which were only 18 by 20 or 19 in. square, and roll four lengths of 100-lb. 33-ft. rails. The height compared to the base was so great that before any shrinkage occurred in the vertical hot ingot walls, the interior shrinking cavities developed so large they could not be prevented entirely from forming, even by prompt charging of the ingots, after stripping, into the reheating furnaces to equalize the heat for rolling.

The 33-ft. 100-lb. rails rolled from four-rail-length ingots of the long type developed in the track a great many split heads and some true pipes, the product from two or three mills being quite pronounced in this respect. Of rails which were rolled during August and September, one purchaser removed in less than six years' service more than 10 per cent. for split heads. The trackmen would report these rails as piped, for the segregated metal in the head would crack under the fillet and admit the air, which would soon discolor the interior surface, and these would be considered as piped rails. There was in some instances a true pipe or shrinkage cavity when rolled, which extended into the centre of the web and well up into the head. The trackmen, however, were not able to distinguish between the true piped rails and the split heads, and it was some time before the latter were attributed to segregation and slag enclosures, which, when recognized, were nearly prevented in subsequent manufacture of rails.

When the mills began to make 33-ft. rails and teemed them into the same ingot moulds which had been used for the 30-ft. rails, and then rolled them in four 33-ft. lengths for 100-lb. rails, a great many ingots were not stripped, weighed and charged into the reheating furnaces with sufficient promptness to prevent a number of piped rails, as the requisite mill practice to check them was not then comprehended under the changed manufacturing conditions.

The segregation was also large, and in 1908, for the New York Central lines, I confined the rolling of Bessemer and open-hearth rails in the United States mills to three 33-ft. rail-length ingots for those of about 19 in. square upon the base. It was also stated in the specifications for the New York Central lines that short, stubby ingots of a length from 2.5 to 3 times the width of the base were required for rails. Ingots of about 8,200 lbs. weight were teemed in moulds 20 by 24 in., and, in good mill practice, will practically complete elimination of piped rails. The blooms, however, were cut, and only rolled in three rail lengths at a time. Ingots 25 by 30 in., of about 12,000 lbs. weight, have been used for eight 33-ft. basic open-hearth 100-lb. rails where the ordinary rail-mill equipment had not been installed. The ingots were bloomed and then shipped to a rail mill to be reheated and rolled, and but a few piped rails were found during manufacture. The rails in the track fulfil the requirements of safety and severe service.

The large mass of metal in the short ingots does not cool quickly, and from the teeming of from 60 to 80-ton melts the ingots would be charged into the reheating furnaces in 1 hr. 30 min., and before all the interior metal had set, with but a trace of a shrinkage cavity started. The distance run by the ingots on their cars from the open-hearth department to the strippers and then to the reheating furnaces aids in consolidating the hot metal in the centre of the moving ingots.

Ingots have been teemed and stripped in the ordinary manner, then taken to the reheating furnaces and when ready for rolling taken out, allowed to cool, and when cut, as would be expected, have shown a shrinkage cavity. The blooms from the companion ingots, when promptly charged into the reheating furnaces and rolled as in proper mill practice, have shown only a small trace of the cavity compared to that in the cold cut ingot.

The specifications for the New York Central Lines require that as soon as the ingots are stripped, they shall be charged into the reheating furnaces to prevent the setting steel cooling from its molten temperature to that of cold metal and to thus avoid the formation of the full shrinkage cavities in the ingots. It has been shown, by the cutting of a large number of blooms, that the shrinkage cavity in the top of the hot ingot is not more than 1/20 to 1/30 of the size of that formed when the ingot is allowed to become completely cold before it is put into the reheating furnace for rolling.

There are only 25 piped rails known to have been found subsequently in service in the track in 65, 70, 75, 80, 95, and 100 lb. sections out of about 1,100,000 30-ft. rails, of which the length of the ingot was not over but under three times the width of the base. The ingots were all stripped by hand in the teeming-pit and charged into horizontal reheating-furnaces, a mill practice long since abandoned. Many 0.06 per cent. phosphorus and 0.60 to 0.65 per cent. carbon rails are still in freight and branch-line service. Some split heads have developed in these rails, due to segregation and the heavy service to which they have been subjected.

Designating Rails by Position of Metal in Ingot.—I was at the mills co-operating in the manufacture and inspection of rails and commenced in 1893 to indicate their position in the ingots by stamping on the web of the top, middle and lower rails the letters A, B, C, respectively. This was for the purpose of studying their subsequent wear and behavior in the track. The A rails contained a larger percentage of oxides, which rose in the steel before completely setting in the ingots, and were faster than the B or C rails under the same traffic. The breakages, however, have been slight in the A, B, or C rails after their many years of service. The ingots were teemed with sharp corners in the moulds, of about 2.5 in. radius, and in the A rails particularly, oxides and slag were entrapped in the corners by the columnar structure of the setting steel. The gauge-side corner of the A rails would show indications of breaking down and spawling to a greater extent under the heavy traffic than the B or C rails. It was possible, after the rails were in the track 8 or 10 years, to identify by casual inspection the A rails from the B or C rails, by the more frequent spawling on the gauge-side corner of the head.

Use of Deoxidizers.—The views of Mr. Benjamin Talbot and Sir Robert Hadfield are old, as to the desirability of completely eliminating blowholes and causing the steel to set sound at the risk of producing a shrinkage-cavity, which must be checked from full development; they have been held and practised by me for the past thirty years in the production of ingots for steel rails. The deoxidizers, apart from the manganese, should be sufficient to cause the steel to set sound without blowholes nearly to the extreme top of the cold ingot. The suggestions of Mr. Talbot and Sir Robert Hadfield, that a large percentage of aluminum be used in the ingots to reduce more completely the oxides, I do not consider advisable. It would be better to use silicon or a combination of silicon and ferro-titanium to secure the desired results. We do not use as high percentages of silicon in steel as is employed abroad, except for tyres.

It is now found for our heavy wheel loads and severe service in the low temperatures of several of the important trunk lines that the high-silicon tyres break more frequently than those in which the content is lower. The suggestion to use from 0.3 to 0.4 per cent. of silicon in rail steel without modification of the other chemical constituents would involve the risk of many rails breaking from the slipping of the drivers upon the rail heads. We must proceed with proper caution in introducing deoxidizers which remain (or whose oxidation products are liable so to do) in the bath of steel. Ferro-titanium, while more expensive than either aluminum or silicon, also acts as a flux, and can be used without danger of leaving its oxidation products in the well-made bath of steel.

Segregation of Basic Open-Hearth Steel Ingots.—The segregation in basic open-hearth ingots for steel rails and wheels has not received requisite attention. I have studied the segregation in several ingots, but do not find it as great in well-purified steel as might be expected with Bessemer metal, which contains two or more times the impurities of phosphorus and sulphur. Well-melted, purified basic open-hearth steel sets quietly and the segregation becomes less in degree.

The Illinois Steel Company, at Gary, when rolling rails for the New York Central Lines in 1912, at my request charged an ingot weighing 8,100 lbs. into the reheating furnace as in ordinary mill practice. In about 2.5 hours, when in condition to roll, it was set outside the furnace to cool. The ingot was 20 by 24 in. on the base and poured 73 in. long. A shrinkage cavity in the cold cut ingot was fully developed from hot to cold steel, and was more than twenty times larger than in the bloom crop of the rolled companion ingot as charged in the usual mill practice. Charging the ingot 10 or 15 min. earlier would have prevented even as large a shrinkage cavity as found in the bloom crop.

Drop and Exhausted Ductility Tests for Open-Hearth Rails.—The exhausted ductility tests for the purification of the steel were introduced into the specifications for the New York Central Lines in 1910 to secure from the preceding eighteen years' experience with the elongation tests Bessemer rails of sufficient toughness to withstand low temperatures of 20 to 30 degs. below zero. The ductility which is possible for a given composition, size of ingots, section and other points of manufacture, has been practically ascertained, and it is to be seen by the exhausted-ductility tests whether or not it is secured.

It requires but a moment to stamp the crop of the rail with the 6-in. spacing bar of seven points before placing the butt on the supports of the drop-testing machine. The elongation of each of the six marked inches on the test butts after the drop is measured by a flexible rule, and the increase in hundredths of an inch per inch indicates the per cent. of elongation. It takes but a moment to test the butt, and the exhausted ductility is obtained in three or more blows through it is measured after each blow and recorded. The lower carbon content of the specification gives one range and the maximum content a higher range, and the mean carbon content is between the two. One of the three can be used as may be necessary in locations for safety, speed and wheel-loads of service.

The term ductility in the specifications for the New York Central Lines is used in the sense of tenacity and toughness of the steel, the exhausted ductility being its measure. This also becomes a soundless test for seams, segregation, slag inclusions and other foreign matter in the web or head of the rails, and is better than the special nick-test in other specifications. The elongation and exhausted-ductility tests are made concurrently with manufacture at the plant under the drop-testing machine on 4 or 5-ft. lengths of the top crop of the rail bars. The butts are tested within 3 hours or less after the ingots of a melt are teemed and rolled, and the facts as to the full ductility of the steel as made and rolled are available for the manufacture of subsequent melts.

Conclusions as to Present Basic Open-Hearth Rail Manufacture.—(1) The chemical composition should provide for

sound steel of ample physical properties of tenacity and toughness rather than hardness combined with brittleness.

(2) The impurities, phosphorus and sulphur, should be in minor amounts, so the bath of metal can be purified to produce the large percentage of toughness and ductility due to the specified chemical composition.

(3) The ingot should have such relations of area of base compared to the height and weight that under good mill practice and with suitable deoxidizers it can be made with controlled segregation and only a trace of a shrinkage cavity in the top; then, when bloomed under its equalized initial heat, it is rendered pipeless by the usual 8 to 10 per cent. discard.

(4) Aluminum can be replaced and silicon partly so, as oxidizers, with advantage by the use of ferro-titanium to purify, solidify and check segregation in rail, tyre and axle steels, and also some of the lower grades of carbon steels where great purity is desired.

(5) The ductility and elongation tests to date furnish the best and only prompt means of determining the degree of purification of the steel per melt as it is made, by indicating the physical properties secured before another melt is tapped from the same furnace, and are of decided advantage to the manufacturer as well as to the consumer. These tests are so advanced that they must be applied with knowledge and understanding for proper results, and not be made mechanically for specified records.

(6) Every process or step of the entire manufacture of the steel and the rolling and finishing of the rails must contribute its part to secure the highest quality of the product incident to the chemical composition.

(7) Specifications should be drawn to indicate some of the major necessities of the consumer, and the tests and inspection should be conducted so as to aid and invite the co-operation of the manufacturers to meet the progressive requirements in rail steel.

OREGON CONSERVATION COMMISSION.

The fourth annual report of the Oregon Conservation Commission shows that unused streams in Oregon are capable of producing 3,300,000 horse-power. These streams are also capable of supplying water to irrigate fully 4,000,000 acres of land, half of which can be irrigated at a cost of $30 to $60 per acre. Of the 686,129 acres of irrigated land in the State, 3.2 per cent. has received water through the United States Reclamation Service, 3.6 per cent. through the Carey Act, 11.3 per cent. through commercial enterprises, and most of the balance through individual or partnership enterprise.

The commission recommends submission to the people of a constitutional amendment providing for a bond issue for co-operation with the United States Geological Survey. It also recommends state construction and control of sufficient power projects to regulate the market and insure cheaper power.

The report contains the complete text of the Water Code of Oregon, with comments on its operation. The law has greatly stimulated investments, and the determination and recording of early rights has progressed rapidly. Twenty-three separate stream systems have already been surveyed, involving about 275,000 acres of irrigated land. Over 2,000 claims to water have been filed with the board, and complete determinations made on fifteen stream systems, affecting 1,018 separate rights and 106,686 acres of irrigated land.

SAFETY FIRST.

A movement which in a short time has attained widespread popularity and been adopted by many prominent railways is that of "Safety First." A paper on this subject was recently read by N. S. Dunlop, claims adjuster, C.P.R., before the Canadian Railway Club, a portion of which we abstract and publish herewith.

The claims adjusters of all the railways in America, who have to follow the investigation of every accident to employees and the public, and finally settle the claims arising therefrom, are credited with originating the "Safety First" plan among railway employees.

They had a strong feeling that if the large number of avoidable accidents and serious injuries to employees were pointed out to them, they would immediately see the necessity for adopting "Safety First" measures for their own personal safety.

According to the report of the United States Interstate Commerce Commission, and the report of the Railway Commission for Canada, for 1911, there were 3,865 employees killed and 130,158 injured—more than 10 employees killed and 3,562 injured every day in the year. A man killed, or injured, about every 24 seconds.

Now, who is paying this appalling toll? Not the public, not the officers, not the clerks. The men who are paying this toll are the men on the firing line in every department of operation, and a close investigation and observation, extending over many years, has shown that from 60 to 90 per cent. of these accidents are preventable, and occur through men taking chances.

The Canadian Pacific Railway adopted the "Safety First" scheme more than a year ago with good results.

Forty-four prominent railways in the United States and Canada have adopted the plan covering 144,329 miles of railway.

On each district committees are formed with a chairman and secretary, and members from every department of operation serve on these committees and hold meetings regularly. The committees are composed of superintendents, agents, engineers, firemen, conductors, trainmen, yardmen, trackmen, freight porters, checkers, roadmasters, sectionmen, etc., etc. Every department has a right to be represented, and every employee of the railway is expected to be a "Safety First" man.

Most of the railways have adopted a "Safety First" button worn by the committee men, and in many cases employees are asking that they be supplied with buttons, to demonstrate their interest in the subject, by wearing it at all times.

If the committee meetings are held during working hours, the committee men are allowed their time and their expenses, if they are away from home.

The investigation of accidents shows that it is the little thing which many people do not bother about that leads up to a serious accident.

Broken boards in freight shed floors, or on passenger platforms, result in broken legs, or ribs. Children are killed, or injured, through allowing them to play on lumber piles and turn tables, and on railway premises. Trackmen are injured by employees throwing ice or empty boxes off moving trains. Brakemen, or yardmen, should never kick over a knuckle, adjust a coupler or angle cock while cars are moving. They may do these things successfully for a long time, but the loss of lives and limbs results too often. These men are chance takers, and the chance taker is the chief supporter of the artificial limb maker and the undertaker.

Employees should always respect the blue flag. The lives and limbs of their fellow employees depend upon it.

Never stand between the rails and attempt to get on an advancing engine or car. If it is necessary to get on either stand outside the rails. Better get on behind.

"Safety First" says emphatically "do not take chances." The time between the prevention of an accident and causing one is only a matter of a few seconds.

Obstruction should not be left near the track for train men to trip over. Drains should be covered at night. Car checkers and others moving about yards should keep from between the rails. They are made for cars and engines to run upon.

The careless, indifferent foreman will have careless men under him, and a greater number of accidents than the man who is always alive to "Safety First."

Look out for loose or missing grab irons, loose brake circles. Do not go under cars without a blue flag to protect you, and see that the car is on its trucks, or so securely blocked up that a change in weather conditions will not tumble it over upon you.

The conductor's highest duty is the protection of his passengers and he should exercise great care in the starting and stopping of his train, and live up to the very spirit and letter of the rule book.

All men engaged in the operation of trains should at all times observe the strictest sobriety, have proper rest, know the rule book by heart, and observe without any quibbling, every rule in the book. They should have no family troubles, and while on duty think of nothing else but duty.

If in doubt, stop. It is better to delay your train than land yourself and your passengers in eternity.

"Safety First" says use torches around your engine and tender, not matches.

Ring your bell before moving your engine off the ash pit.

Do not stand between the apron and the cab when coaling an engine.

Lower your crossing gates in time. Keep clear of passing trains.

Avoid flying stones, or objects falling off a train.

Do not fool with machines—they can be replaced, hands cannot.

Look out for gang planks when loading freight into cars. Do not allow freight handlers to go in their bare feet. They may step on nails and death by lockjaw is sometimes the result.

"Safety First" warns you that it is better to make your slings and scaffolds safe and to use four inch nails instead of 2½ inch nails. It is better to spend five minutes making things safe than to be taken home with a broken back.

Never allow jacks, angle bars or material near the track where they may be struck by a passing train.

When riding hand cars send a man ahead towards a curve, and, if you are likely to be caught and cannot remove the hand car, "Safety First" says: "Let the hand car go and run towards the engine." Hand cars cost $49.40 each. Human lives can never be replaced. Do not carry guns on hand cars and arrange tools so that they will not fall off.

"Safety First" says to men engaged in blasting: "Do not carry a whole box of 100 detonator caps in your pocket. Two or three are sufficient. An explosion means shocking results."

Men should tell their fellow employees of the dangers of their work before an accident happens, and warn them how to avoid it.

Never approve the actions of careless men. Caution them for their own good and for the good of others.

The vast importance of "Safety First" is demonstrated in the words themselves. You may write volumes on these two words, analyze them, describe their objects, explain them any way you like, but you cannot add to the emphasis of that slogan which is bound to reach more railway men, and be of vastly more importance, than any subject they have ever taken up.

On a large number of railways special men have been appointed whose duties are solely to educate the men on "Safety First" habits. This is done by printed literature, lectures, moving pictures showing the right and wrong way of doing work, correcting defective conditions and impressing upon the minds of all classes of employees the danger of taking chances.

In the operation of a railway "Safety First" should be placed above everything else. Unless men are willing to be careful and avoid injury to themselves and their fellow workmen, they should not engage in railway work. A railway does not want careless men in its employ. "Safety First" is always a great convenience, but in an emergency it is an absolute necessity.

The "Safety First" habit must be the creed of every railway man who hopes to succeed in the prevention of preventable accidents.

If whisky or beer interferes with a railway man's work he should give up his work.

Do not ride between crippled cars.

Pile up lumber in yards, drive down grade stakes, fill up holes, turn down boards with nails sticking out of them, and remove anything a train man may fall over.

Do not, under any consideration, go between moving cars.

Do not allow telephone or telegraph wires to hang too low over tracks. Cut them before some poor fellow is knocked off the top of a car and paralyzed for life.

Teach men to be careful. Do not overload engine tanks with coal.

Whenever an employee is killed, or injured, sorrow, suffering, expense, and, if he lives, crippled earning power, is the result.

Do not allow a man with one eye to work where cars are being moved. He cannot see from the blind side.

Do not leave dynamite, torpedoes or fusees where children can play with them, and do not carry them in your pocket.

"Safety First" never sleeps. It says: "Report and have corrected as soon as possible anything which would cause an accident." It calls at all times for suggestions and ideas, from employees, how to save men's lives and limbs.

DISCUSSION ON "SAFETY FIRST."

Prof. Keay: I think the author of this paper is to be congratulated upon having expressed so much logic in so brief a space. The paper is further to be commended for its intimate and human appeal. That it enters a field far wider than that of the railroads alone is evident from a recent request which I have from the assistant manager of one of the largest shipbuilding companies on this continent, for the bibliology of all railway literature available on the "Safety First" movement. This may be regarded as a frank recognition that the railways are the first in the field. It seems to me that the underlying principle of this movement is a practical answer to that old question: "Am I my brother's keeper?"

Mr. A. A. Maver: The subject of this paper is one of great interest to me, and it is also of great and first importance to all employees, not only in railways, but in industrial establishments of all kinds. It is also of interest to employees, and especially since the Employers' Liability Act has come into force, whereby the employer is held responsible, no matter how neglectful or careless the employee may have been in becoming injured. I was at a meeting in connection with "First Aid to the Injured," and one of our officials spoke on the subject of prevention. He said, "You gentlemen here have purposed to care for and give attention to the injured, but the greatest point of all is prevention"—and he brought in the old adage, "An ounce of prevention is worth a pound of cure." Safety first is prevention. I have noticed in connection with our works, and in the casualty reports which come before me, that the higher the intelligence of the employee the less injuries are sustained, but the lower the grade of intelligence the greater the number of injuries. This is particularly true in the case of our foreign labor, which men are generally of a very low order of intelligence. They are handicapped also by not speaking our language, and, in fact, have to be led out of danger by other employees. The great trouble is that their fellow-employees, who have more intelligence, give them credit of having an equal intelligence, and the result is they are often not warned as they should be. Mention is made in this paper of keeping torpedoes out of the hands of children. These torpedoes are used for the protection of trains during fogs or heavy snow storms, when the visual signals cannot be readily seen, the explosion warning the engineer of danger ahead. They are supposed to be removed from the locomotives when they are sent to the shop for repairs, but occasionally one is left on an engine, and it gets into the shop. It is gotten hold of by some inquisitive man, who sees in it an explosive of some kind, and who slyly puts it under a locomotive which may be moving in or out of the shop. As the wheels pass over it an explosion takes place, the metallic casing flies in all directions, and we have had some serious accidents from this cause; but it is always difficult to find out who put the torpedo on the rail. We had a case of one young man who wanted to hear what kind of a report a torpedo would make. He placed one on a piece of metal, got a hammer and struck it. He not only heard the report, but also had a very badly mutilated hand. This is all through ignorance, yet warning notices have been put up. It seems to me a duty on the part of our employees to point out to their fellow-employees where the danger exists. If this is done a great many accidents would be avoided.

CIVIL SERVICE COMMISSION.

Applications will be received by the Civil Service Commission for the following positions: A correspondence clerk in the Forestry Branch of the Department of the Interior, an assistant engineer in ore dressing and metallurgical division of the Mines Branch of the Department of Mines, twelve technical clerks for temporary employment in the Topographical Survey Branch of the Department of the Interior, and a draughtsman in the Forestry Branch with a knowledge of survey work and general drafting.

Application forms, properly filled in, must be filed in the Office of the Civil Service Commission, not later than the 26th May in the case of the first two and the last positions, and not later than the 19th May for the technical clerks in the Topographical Survey. Forms may be obtained from Wm. Foran, the Secretary of the Commission, Ottawa.

COAST TO COAST.

Ottawa, Ont.—Accompanying is a table showing the results of an analysis of the water supply about to be brought from Esquimalt, as determined by City Analyst Birch. At Elk Lake, "A"; Goldstream, "B"; Sooke Lake, "C"; Richardson Street spring, "D"; and Spring Ridge spring, "E":

	Free Ammonia	Albuminoid Ammonia	Chlorine	Volatile Solid	Fixed Solids	Total Solids	Nitrates	Nitrates	Reaction
A	.001	.012	.6	3.2	4.2	7.4	.00	.00	Neutral
B	.001	.003	.5	1.5	2.5	4.0	.00	.00	Neutral
C	.001	.008	.5	2.0	.4	2.4	.00	.00	Neutral
D	.000	.001	1.3	6.0	8.5	14.5	.5	.00	Neutral
E	.000	.003	4.2	12.5	25.0	37.5	.8	.00	Neutral

The first two columns are parts per 100,000, and the others in grains per gallon. From the standpoint of purity the albuminoid ammonia as determined from Wanklyn's process, gives the best idea of the purity or otherwise of the water from contamination, taking in view, of course, the amount of free ammonia and chlorine which would be found in excess in water fouled by excreta. That at Elk Lake is slightly lower than the British standard of 0.015; however, it is safer in this country with a higher percentage than in Britain on account of the less densely settled communities. Therefore, bad as Elk Lake supply has been in summer from the point of odor, it has practically no injurious effects, although last year at one time it was felt desirable for the board of health to issue a warning on the subject to the citizens about boiling it. The two city springs are, of course, remarkably pure.

Toronto, Ont.—The Toronto delegates attending the fifth National Conference on City Planning at Chicago have returned. The party consisted of Aldermen S. Morley Wickett and H. J. Anderson, Geo. Powell, Assistant City Engineer; Chas. E. Chambers, Parks Commissioner; Jas. C. Forman, Assessment Commissioner; Messrs. Dunington-Grubb, J. P. Hynes, and E. L. Riggs, of the Civic Guild, and Miss E. B. Neufeld, of the Central Neighborhood House. At the conference were 230 delegates, representing 53 American cities outside Chicago, and six Canadian cities. These composed the best authorities on the subject in America. A great development of the park and boulevard system is being carried out in Chicago. The parks in the city have been linked together by magnificent boulevards about 150 feet wide, splendidly paved and most efficiently maintained, and marked with a cleanliness which is most striking. In a huge semicircle these driveways surround the city, and the base is formed by Michigan Boulevard. In all, there must be between 50 and 60 miles of continuous roadway. This was one of the most impressive works they had seen, stated Mr. Riggs, and pointed out that as the geographical situation of Toronto was practically the same as that of Chicago, the plan they are carrying out there could easily be adapted to our own city. This plan has been already outlined for Toronto by Parks Commissioner Chambers, who stated: "The boulevard system made us envious. Alderman Anderson and I are going to prepare reports on both these features to be submitted to Council soon, and in the hope that Toronto may do something along the same line." Mr. Chambers said that while nothing was known as yet to the choice for the 1914 convention, Toronto would likely be the convention city. Twenty-five cities sent invitations, but Toronto will get the convention. "If they come here we will

make the association an international one," said the commissioner. "It will be the first town planning congress to be held in Toronto."

Victoria, B.C.—While the effort to obtain national government participation in the highways progress of the United States accumulate force, the various states, one after another, are adopting legislation providing for the establishment of state highway departments. According to information received by the American Automobile Association National Good Roads Board, which keeps in touch with the state automobile bodies and aids materially in their work, there will be, as a result of recent legislative action, road departments in Maine, Montana, Missouri, Colorado, Idaho, Arkansas and Texas. This makes plainly apparent that the move for federal action has not caused any "lying down" on the part of the states, which have their proper part to perform in the general roads development. Of the addresses given at the second federal aid convention in Washington, called by the National Good Roads Board, none contained a more comprehensive summing up of the situation than the remarks of Representative William P. Borland, of Missouri, who, among other things, said: "I believe that the good road question is the biggest question, without exception, now facing the American people. In Congress we are trying earnestly and sincerely to deal with this problem of the extent and character of federal control and federal aid to good roads. There are difficulties confronting us. Some of us believe in a continuous system of roads, roads that go somewhere, roads that give us the benefit of the scientific progress of engineering skill that has been developed in connection with road building. We believe that federal aid, if it comes at all—and it must come—must mean a better type of roads, long roads, roads of higher class, roads of a more permanent character, roads that go somewhere, roads that mean something in the development of the country. But here is the idea that must occur to every thinking man. We do not have to improve the 2,150,000 miles of highways in the United States. That need not stagger any man's imagination. Experience has shown, at the very threshold of this subject, that 90 per cent. of the traffic on roads goes over less than 10 per cent. of the roads. If we had a system of good roads leading fairly into every section of the country, within the reasonable reach of the majority of the citizens and producers and taxpayers of the country, that system would be a vast advantage over the present system of isolated local control of highways. If we can bring that about by a spirit of self-sacrifice and co-operation, and if we can get together on the idea that it is better to have some good roads than it is to have no good roads, then we will all get behind some proposition and accomplish something for good roads, and it is going to take that spirit of co-operation and self-sacrifice to bring about legislation."

Quebec, Que.—That there is little prospect at present of any Government action towards securing the refining in Canada of silver ore which now goes to New York for the final process, but that the Government expects to shortly enlarge the refinery at the Ottawa Mint so that it will be able to take care of the whole gold production of the Dominion, were announcements made in the Commons recently by Hon. W. T. White, Minister of Finance, in the course of a discussion on a bill increasing from $75,000 to $110,000 per annum the vote for operating expenses. Sir Wilfrid Laurier suggested that in view of the fact that practically all the Canadian silver output, amounting last year to $19,000,000, went to New York for refining purposes, the Government should take steps to encourage silver refining in Canada. Mr White, however, said that economic conditions of refining and marketing and considerations of technical processes, made it impracticable at present to change the present refining and marketing and considerations of policy of centring the silver refining industry on the large and costly American plants.

Toronto, Ont.—The supply of iron ore available under present methods of mining in the entire world has been stated by geologists of international reputation at 22,000,000,000 tons, from which it is estimated 10,000,000,000 tons of iron may be produced. At the present rate of consumption, this supply would last the world about sixty years. There are, however, more than 123,000,000,000 tons of ore not now commercially available, which, with improved methods of production, may be made to yield in the future an additional 53,000,000,000 tons of iron, which would run the world along for another 300 years, if no more iron were used annually than at present.

Winnipeg, Man.—The construction of the Canadian Pacific Railway tunnel under the Selkirk Mountains, for which the contract has been let, will be a tremendous undertaking. Owing to the fact that the tunnel work cannot be accelerated because of the impracticability of driving shafts a mile deep through the mountain, work on the tunnel proper will be necessarily confined to two ends. This will make work slower of accomplishment than if, as in the case of the Canadian Northern tunnel under the mountain into Montreal, a shaft could have been sunk near the centre of the tunnel. If this had been practicable, four shifts could have been employed in tunnelling night and day, and work would have been greatly expedited. As it is, only two shifts can be used night and day on the two drilling surfaces. Some difficult engineering feats are being faced in building the approaches, but these pale into insignificance in the presence of the vaster task of piercing the mountains. Besides this, twenty miles of double tracking, which is now being undertaken in connection with tunnelling, the Canadian Pacific is also asking for tenders for forty-nine miles more of double tracking in the mountains. Twenty-five miles of track are to be built east of Kamloops and twenty-four west of Revelstoke.

Montreal, Que.—The Phœnix Bridge and Iron Works Company is making a new issue of bonds and stock this week, through the Quebec Savings and Trust Company. This stock has already been underwritten, and is now being distributed to the public. The offering consists of $750,000 of 6 per cent. first mortgage bonds, and of $800,000 of common stock. The bonds are being offered at 96 per cent of par, and the stock at $50 per share. The offering is being made simultaneously in London and in Canada. Approximately $450,000 of the bonds and $405,000 of the stock have been taken firm. A new company has just been incorporated at Ottawa with a capitalization of $1,500,000. This company in every way takes the place of the company which has heretofore operated under the same title. After the present issue has been accomplished, there will remain in the treasury to provide funds for future expenses and for the general purposes of the company, $700,000 of the common shares of the company. All the bonds will have been issued. The company has a plant situated in the centre of the manufacturing district of Montreal, where shipping facilities are all that could be desired. The concern manufactures and erects structural steel for bridges and buildings. The cost of delivery, owing to the central location of the concern, is smaller than in the case of most other companies. Operations have now been carried on satisfactorily since 1898, and, save for an occasional year, earnings have shown a fairly constant increase, beginning with $51,000 in 1898 and progressing gradually to upwards of $600,000 during the past couple of years. The land owned by the company allows of an expansion to the works. The assets of the company, at the end of last year including $25,000 which is being provided for improvements, amounted to $1,400,00, while total liabilities were but $57,000. This leaves a surplus of $1,243

against the present bond issue of $750,000. Mr. James W. Pyke is president of the company, and Mr. T. Palmer Howard is general manager.

Victoria, B.C.—Plans for harbor improvements progress steadily. This year Victoria will have its large docks under way. These are to be built by Sir John Jackson & Company, and something will be accomplished also in connection with the dredging of False Creek in Vancouver. To give better facilities for shipping, it is announced that the government will establish a drydock at Esquimalt, this being stated as part of the naval scheme on the Pacific. Mayor Baxter, of Vancouver, who was in Vancouver in connection with harbor and other matters, returned on the 1st instant, and reports that it is very probable that a drydock will be built at Vancouver along the lines of some of the schemes proposed heretofore. News of the government grain elevator is also brought back by the mayor. He does not say, however, that this will be erected right in Vancouver, but it will be close enough for this city to reap benefit from the business Along the waterfront of Vancouver there is hardly room for a large grain elevator, since it is a very busy place. Moreover, if an elevator is erected some distance out it will help to give strength to the outlying reaches of Greater Vancouver. With the passage at Ottawa of the bill to incorporate the harbor commissioners of Vancouver, no time should be lost in completing the personnel of this board, so that this legislation may be effectively implemented. It will be found that there will be many matters for a board of this kind to adjust and adjudicate upon, and if trade grows as it has in the past, and as is anticipated, the harbor commissioners will be kept down to steady business.

Montreal, Que.—The Montreal Engineering Company, Limited, of Montreal, has been given a franchise by the Medicine Hat council to build and operate a street railway system. The by-law will be submitted to the burgesses on May 22nd, when it is expected that the agreement will be approved. The franchise is for a twenty-year term, renewable for a further term of five years or more. Construction will commence June 1st and rushed to completion of the first nine miles of track. Power will be supplied by the city as alternating current, or the company will install its own plant, operated by natural gas supplied by the city.

PERSONAL.

C. H. MITCHELL, C.E., has been appointed a member of the Board of Governors of the University of Toronto.

H. GALE LEGG, town engineer of Preston, Ont., has been appointed to a position in the chief architect's office at Ottawa.

WM. C. SAMPLE, consulting engineer of Fort William, Ont., has been called in by the Township of Neebig, to report on a sewage disposal scheme.

MR. E. J. HOLLAND, acting city engineer of Guelph, Ont., has been appointed city engineer. Mr. W. C. Clauson has been appointed assistant city engineer.

MR. A. T. ENLOW has resigned as manager of sales of the Stark Rolling Mill Company, Canton, Ohio, and has become associated with the Pedlar People, Oshawa, Ont.

MR. H. M. KENZIE, at present in the employ of the water power branch of the department of the interior at Ottawa, has been appointed as city commissioner of Prince Albert, Sask.

GEORGE H. BOWEN, B.A.Sc., has opened an office as consulting, mechanical, and electrical engineer at 34 Victoria Street, Toronto. Mr. Bowen graduated from the University of Toronto in 1909, and latterly has been connected with the Niagara Falls Park Commission.

PROF. R. B. MILLER, dean of the U.N.B. Forestry School, has accepted a position with the forestry branch of the Department of Natural Resources of the C.P.R., for the summer to do consulting work similar to that done by Prof. A. H. D. Ross, of Toronto University, in British Columbia.

MR. F. P. GUTELIUS has been appointed general manager of the Government Railways. He is appointed for a two-year term. He will supervise and direct all departments of the Government railways, and will be in charge of the Hudson Bay Railway when completed. The order provides for the abolition of the present Intercolonial Board of Management. Mr. F. P. Gutelius was born in the United States in 1864; he graduated as a civil engineer in 1887, and started to gain experience with the Pennsylvania Co., Pittsburg, Pa. He went to British Columbia in 1895 and was general superintendent of the Columbia and Western Railway (constructing and operating railway between Robson and Rossland) till 1895, when he joined the C.P.R. He successively held positions as division superintendent, in the Engineering Department, as engineer of maintenance of ways, and became assistant chief engineer of eastern lines in 1906, general superintendent of Lake Superior division in 1908, and superintendent of the Eastern division in 1910. Early in 1912 he was appointed by the Government to investigate all expenditures on the National Transcontinental Railway. He will have his headquarters at Moncton, N.B.

PROFESSIONAL DEGREES GRANTED BY UNIVERSITY OF TORONTO.

The following have completed the requirements for professional degrees as laid down by the University of Toronto:—F. A. Dallyn, the degree of civil engineer (C.E.); E. A. James, the degree of civil engineer (C.E.); C. H. Marrs, the degree of civil engineer (C.E.); D. L. H. Forbes, the degree of mining engineer (M.E.); A. G. Christie, the degree of mechanical engineer (M.E.); E. H. Darling, the degree of mechanical engineer (M.E); G. J. Manson, the degree of mechanical engineer (M.E.); R. S. Smart, the degree of mechanical engineer (M.E.); P. H. Mitchell, the degree of electrical engineer (E.E.).

THE AMERICAN INSTITUTE OF CONSULTING ENGINEERS.

A meeting of the Institute for the purpose of discussing "The Incorporation of the Institute," also "The Physical Valuation of the Railroads of the United States as Authorized by Act of Congress, March 1, 1913," will be held at the Engineers' Club, 32 West 40th Street, New York City, Thursday evening, May 22nd, 1913, at 8 p.m.

TECHNOLOGY CLUB OF LOWER CANADA.

The Alumni of the Massachusetts Institute of Technology met last week in Montreal for the purpose of forming an Association to be known as the "Technology Club of Lower Canada."

The club includes among its members this Alumni of the Institute now residing in Eastern Ontario, Province of Quebec and the Ottawa Valley. The following officers were elected:—President, Mr. F. E. Came; vice-president, Mr. H. E. Stearns; secretary-treasurer, Mr. E. B. Evans; board of governors, Mr. D. J. Spence and Mr. R. Heckle.

The club will have two regular meetings each year, as well as a weekly meeting at a local restaurant for the purpose of forming the object of the organization.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

The spring meeting will be held this year at Baltimore, Md., May 20th to 23rd, inclusive, at the invitation of the Engineers' Club, of Baltimore, and the local members of the society. The professional sessions have as usual been arranged by the Committee on Meetings, while all other events are in charge of the local committee under the chairmanship of Layton F. Smith, past president of the Engineers' Club, of Baltimore.

Special railroad transportation concessions have been secured for members and guests attending the spring meeting in Baltimore, May 20th to 23rd, 1913.

The special rate of a fare and three-fifths for the round trip, on the certificate plan, is granted when the regular fare is 75 cents and upwards in United States territory.

COMING MEETINGS.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Spring Meeting, May 20-23. Secretary's Address 29 West 39th Street, New York.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE CANADIAN FORESTRY ASSOCIATION.—National Convention will be held in Winnipeg, Man., July 7-9. James Lawler, Secretary, Canadian Forestry Association, Canadian Building, Ottawa.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

NATIONAL ASSOCIATION OF CEMENT USERS.—Tenth Annual Convention to be held at Chicago, Ill., Feb. 16-20, 1914. Secretary, E. E. Kraus, Harrison Bld., Philadelphia, Pa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Muckleston; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson, Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290. Meets 2nd Thursday in each month at Club Rooms, 534 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSIOCATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, The Thor Iron Works, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Keilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Edmund Burke; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

TECHNOLOGY CLUB OF LOWER CANADA.—President, F. E. Came; Secretary-Treasurer, E. B. Evans. Meets twice yearly.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

An Engineering Weekly

TEST-LOADING UNTIL BREAKING POINT OF A 100--FOOT ARCH BRIDGE.

By V. J. ELMONT, B.Sc., A.M. Can. Soc C.E.

On account of an exhibition in Düsseldorf, manufacturers interested in the cement industry decided to build a concrete arch bridge on the exhibition ground. It was the intention to let this bridge enter into the future street layout, and it was, therefore, designed for a 25-ton steam roller and 80 pounds per square foot uniformly distributed. Later on, however, circumstances occurred which made it necessary to change the street layout and remove the bridge, as it was of no use in the new scheme. An extraordinarily good opportunity was thereby given to test-load an actual concrete construction to destruction point, and make a very desirable comparison between theoretical and practical results.

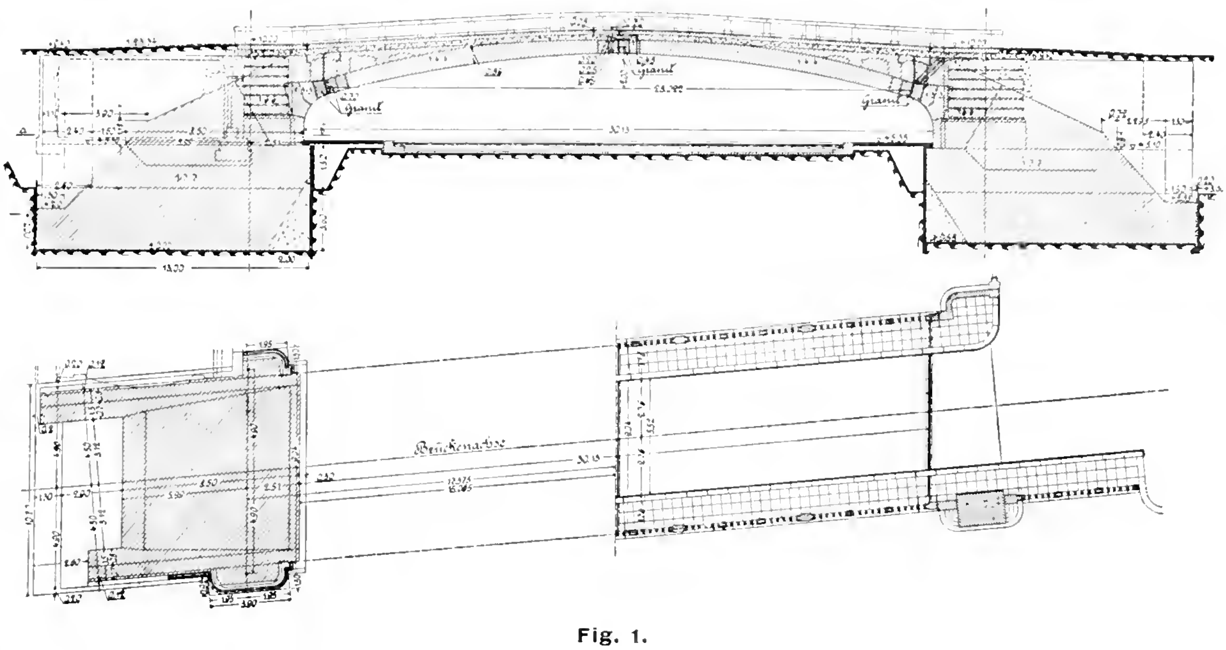

Fig. 1.

The German Concrete Society undertook the planning of the loading and carrying out of the measuring was entrusted to the Government Testing Institute at Berlin.

The span of the bridge was 91.9 feet, the rise 6.6 feet and the width 29.5 feet. There were arranged 3-foot granite hinges with 6.88 and 8.00 feet radius, and the thickness of the arch was 2.8 feet between the hinges. The concrete mixture was 1:4:4. Before loading was commenced a wooden falsework was built up under the bridge, strong enough to bear the bridge and the loading materials when the breaking point was reached. The fill concrete over the arches was removed in order to figure out the stresses due to the test-load as exactly as possible; this concrete, having been a 1:6:6 mix, had become so hard during the six years the bridge was used that it would have influenced the results of the test due to its statical co-operation.

The following measuring apparatus was used in the test:

For determination of the angle-turning of the abutments a level was used on both sides (the bridge was situated close to the Rhine, in the direction north to south) over each of the four abutments.

The vertical and horizontal movements of the abutments were measured by the apparatus shown in Fig. 2. A pin (a) was fastened to the stones with gypsum, and this pin was connected with two wooden arms which, by means of rubber bands, were held in touch to two rolls (2 and 3 in Fig. 2) whose turning could be read off.

The turning of the huge stones was measured by levels on the land side. On the Rhine side pieces of plate were fastened to each hinge, which overlapped each other. For each loading stage a line was drawn in the plate below along the edge of the plate above, and the neutral position of these lines determined the turning angle.

The deflection of the arches was measured on both sides of the bridge and at three points for each arch, and for the whole bridge at 12 points, by the apparatus shown in Fig. 3.

At the crown of the arches common inch scales were used, as greater vertical movements could be expected there.

It being an assumption for the correctness of the measuring that the piles, which carried the apparatus, were standing firmly, an investigation was set on foot to prove it. In a distance of 9 feet from the bridge a pile was driven opposite each of the apparatus. The piles were connected in pairs with timbers carrying levels. These did not show any movement during the loading of the bridge.

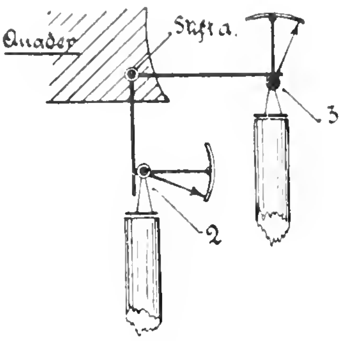

Fig. 2.

To determine the position of the resulting forces in the different sections of the arches and the value of the compression and tension stresses along the intrados and extrados a number of elongation measurements were taken at the centre of the arches by means of Martens mirror apparatus (Fig. 3 a), which give a minimum reading of 1/125,000 of an inch, and at the ends by an index apparatus (Fig. 3 b) which gives a reading of 1/60,000 of an inch. In the Martens apparatus the one end of the measuring spring is supported by a pin (p) put into the arch two inches from the edge, and between the other end and the pin (q) the mirror is placed. A change in the distance between the two pins effects a turning of the mirror to the right or the left, whereupon the variation in the length can be determined by telescope reading in the usual manner. From the elongations the stresses can be figured out directly. For the index apparatus the principle is similar. A lengthening or shortening of the measuring length effects a movement of a cylinder, connected with a long index, whose turning can be read on a scale.

On the Rhine side only were placed apparatus at the centre of the arches, at the top and below. Here was used the Frankel-Leuner's instrument, which had a turn-over ratio of 1/140 only. The alteration in the length is through a lever system carried over to a writing pin, which notes its movement on a paper roll drawn by a clock-work mechanism.

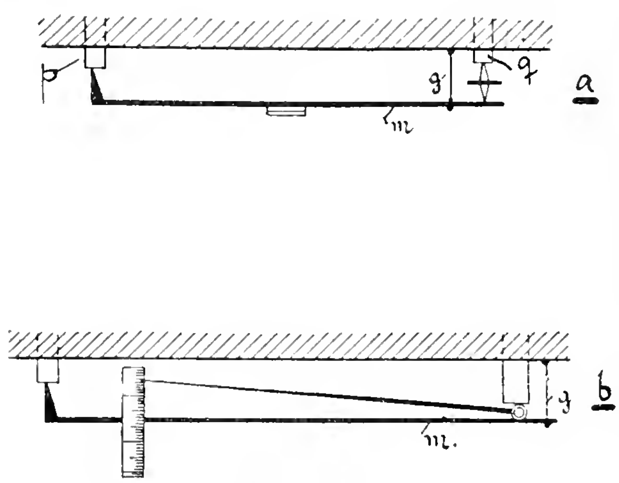
The loading consisted of pieces of steel placed on the southern half of the bridge, over an area 16 feet long and 26 feet wide. It had first been proposed to load the arch from the crown to the springing line, but this plan was given up, owing to the difficulty of procuring a sufficient quantity of steel.

As the weight on the bridge had reached 75 meters, the instruments were read for the first time, and thereafter the reading was continued during the loading. For each loading stage a measurement was taken every fifth minute, until no further alteration in the position could be seen.

The results of the observations are graphically shown in Fig. 4, which gives the alterations in the centre lines of the arch on the land side by loading increases of 75 tons; the curves give the vertical and horizontal movement of the abutment and the vertical movement of the crown, and the centre of the unloaded arch half; the measuring on the land side agreed perfectly with those on the Rhine side.

The increasing load produced first a uniformly increasing deflection at the crown and a curving and raising of the unloaded arch. In Fig. 4a and 4b is shown the movement of the arch axis under a load up to 225 tons. From Table I. it will be seen that this load gives a deflection at the crown at 2.2 of 1/25 inch and a raise in the centre of the unloaded half of the arch of 1.3.

As the test-load was increased to 225 tons a sudden change took place in the direction of the movements, due to a crack which had formed in the arch at the edge of the load. (Fig. 5). The testing institution speaks concerning this crack in the report of the experiments in the following way:—



Figs. 3a and 3b.

An hour before the load 150 tons was reached, as the load of the steel on the bridge was nearly 124 tons, more cracks, which probably did not go very deep into the concrete, were seen at the underside of the loaded part of the arch. A short time after the steel load had reached 140 tons the very fine crack (a, Fig. 5) which could be seen from the start of the experiment, commenced to enlarge, so that it could be seen under the whole bridge, and at last appeared on the Rhine side of the bridge. (Fig. 5).

At all the instruments, however, it was found that the movements of the bridge first started to go in the opposite direction to what had been the case before, when the load was 225 tons. It must, therefore, be assumed that the crack

Table I.

Point.	Movements in 1/25 of an inch. 75 Tons.	150 Tons.	225 Tons.	300 Tons.	400 Tons.
In vertical direction—					
Crown	—1.1	—1.6	—2.2	+0.5	+29.2
